INCREMENTS.

INCREMENTS, Method of, called by the French *Calcul des Différences Finies*, is a branch of analyſis invented by the learned Dr. Brook Taylor, particularly uſeful in the ſummation of ſeries, and applicable to ſeveral ſubjects of mathematical inveſtigation, where ſcarcely any other method can be ſucceſsfully employed. Montucla obſerves, that had the human mind always purſued the path which appears the moſt natural, the theory of increments, or of finite-differences, would have preceded that of fluxions, or the differential calculus; as it ſeems more natural for the mind to be carried from the conſideration of finite differences, to that of differences indefinitely ſmall, than that the latter ſhould be the precurſor of the former. Such, however, was the fact; for the firſt diſtinct notions of the method of increments did not appear till the year 1715, in a work entitled "Methodus Incrementorum," &c. by Dr. Brook Taylor, in which both the direct and inverſe method of increments are treated of in a very learned manner, and an application of the ſame to various intereſting problems; but the novelty of the ſubject, and the conciſe mode of expreſſion employed by its author, together with the very complicated notation, rendered the work nearly unintelligible to any man leſs ſkilled in analyſis than the author himſelf; even the enunciation of ſome of the propoſitions requires the greateſt poſſible attention in order to comprehend their meaning; but in other reſpects, the work bears ſtrong and evident marks of the lofty genius of its author, and contains, in the ſecond part, many very excellent applications of the preceding theory to the ſolution of ſome of the moſt intereſting and celebrated mathematical problems. Such, however, being the intricacy of the original work, it neceſſarily follows that it could only be read by the very firſt rate mathematicians; and it was therefore fortunate that any of them would condeſcend to illuſtrate a ſubject in which they could only act a ſecondary part; ſuch a perſon was however found in M. Nichole, of the Royal Academy of Sciences, who, having very early been in poſſeſſion of a copy of Dr. Taylor's work, and perceiving, at once, its general utility, he undertook the taſk of illuſtrating the principles upon which it reſted; and, by ſimplifying the notation and operations, rendered it intelligible to readers of an inferior order: his firſt paper on the ſubject was publiſhed in the Memoirs of the Academy for 1717, which was afterwards followed by two others in 1723 and 1724. Dr. Taylor himſelf alſo, in the Philoſophical Tranſactions, undertook an explanation of certain parts of his work, and its farther application to ſome kinds of ſeries beyond thoſe treated of in the original: the ſame was alſo done by M. Montmort, in the Tranſactions for the years 1719 and 1720; which latter gentleman, it ſeems, had conceived ſome idea of the theory before Dr. Taylor's work appeared; and a trifling altercation took place between them as to the originality of ſome of the notions which was claimed by both parties. In 1763, Emerſon publiſhed his "Method of Increments;" a work which, at leaſt, does this author as much credit as any that he ever produced; but the notation reſembles, in a great meaſure, that of Dr. Taylor, which renders it now almoſt obſolete. Emerſon appears to have been extremely anxious to bring the theory of increments to perfection; and earneſtly urged thoſe who were qualified for the taſk, to purſue the paths he had opened to them. "I cannot," ſays he, "promiſe that I ſhall have time and leiſure hereafter to proſecute this ſubject any farther. And as I have an earneſt deſire of advancing truth and improving ſcience, let me here

Strahan and Preſton,
New-Street-Square, London.

entreat the friendly mathematicians, who are lovers of ſcience, to lend their kind aſſiſtance for the advancement of this uncultivated branch of knowledge, yet in its infancy, or rather, as yet, in the hands of Lucina, either according to the model I have here laid before them, or ſome better if it can be found, ſo that, by degrees, it may at length be brought to perfection." Hence it appears that this author was, in 1763, ſenſible of the neglect that had been paid to the theory of increments; and even now, near half a century after this date, the ſubject has not been advanced, nay ſcarcely touched upon by any Engliſh mathematician, while foreign authors are filling quarto volumes with the theory of *differences finies*, and its almoſt univerſal application to the moſt curious and important of mathematical inquiries. Euler, whoſe univerſal genius led him to the inveſtigation of every ſubject that was uſeful and intereſting, did not leave the theory of increments untouched, but has treated of it, in his uſual maſterly ſtyle, in a work entitled "Inſtitutiones Calculi Differentiales," &c. in which he has given a new form, and much extended the bounds of this important branch of analyſis: and ſubſequent authors have adopted his ideas, and rendered permanent the form he gave it. Various other works have ſince appeared to illuſtrate and render familiar the principles of this doctrine; the moſt complete of which is the "Traité des Differences," &c. par Lacroix. Boſſut has likewiſe a chapter on this ſubject in his "Traités des Calcul Differentiel," where the theory is treated in a very elementary and comprehenſive manner; and the ſame is alſo done by Couſin, in chapter 3. of the introduction to his "Traités de Calcul Differentiel," &c.

Having thus given a brief ſketch of the hiſtory and progreſs of the method of increments, we ſhall now endeavour to explain the principles and application of it: in order to which, that we may prepare the reader for the more general theory, it will be uſeful to conſider the ſame in a more limited form in the firſt inſtance, in doing which we cannot have a better model than that of M. Nichole above-mentioned.

The method of this author is extremely ſimple, but certainly leſs general than that of Dr. Taylor; it is, however, well calculated for conveying the firſt clear and connected ideas of this theory, and prepares the reader for more general reſearches, by leading him on, from ſtep to ſtep, with order and preciſion.

If we conſider x as any variable quantity, which is continually increaſed by a conſtant quantity n, ſo that it becomes ſucceſſively x, $x + n$, $x + 2n$, &c.: and if y be any function of x, made up of factors, as $y = x\,(x + n)\,(x + 2n)\,(x + 3n)$, then the difference between this value of y, and that which it becomes when x is again increaſed by n, is the increment of y, or of $x\,(x + n)\,(x + 2n)\,(x + 3n)$; which increment is readily obtained, by obſerving, that

$$(x + n) \quad - \quad x \;\ldots\ldots\ldots\ldots\; = n$$
$$(x + n)\,(x + 2n) \quad - \quad x\,(x + n) \quad = 2n\,(x + n)$$
$$(x + n)\,(x + 2n)\,(x + 3n) - x\,(x + n)\,(x + 2n) = 3n\,(x + n)\,(x + 2n);$$

and hence generally, the increment of $x\,(x + n)\,(x + 2n) \ldots (x + rn) = (r + 1)\,n\,(x + n)\,(x + 2n) \,.\,.\, (x + rn)$: And hence again converſely, the integral of $(r + 1)\,n\,(x + n) \ldots (x + 2n)\,(x + rn) = n\,(x + n)\,(x + 2n) \ldots (x + rn)$; or more generally, the integral of $x\,(x + n)\,(x + 2n) \ldots (x + rn)$

$$= \frac{(x - n)\,x\,(x + n)\,(x + 2n) \,.\,.\, (x + rn)}{(r + 2)\,n}:$$

Again, the increment of x^m is the difference between x^m and $(x + n)^m$. Now $(x + n)^m - x^m = m\,x^{m-1}\,n + \frac{m\,(m - 1)}{1\,.\,2}\,x^{m-2}\,n^2 + \frac{m\,(m - 1)\,(m - 2)}{1\,.\,2\,.\,3}\,x^{m-3}\,n^3 + \&c.$; and by means of this general expreſſion, for the increment of x^m, we readily deduce the increment of any function of x, as $x_m + a\,x^n + b\,x_r +$ &c. Thus, for example, if it were required to find the increment of $x^3 + 3x^2 + 4x$, we have increment of $x^3 = 3x^2\,n + 3x\,n^2 + n^3$

$$\text{———— of } 3x^2 = \qquad 6x\,n + 3n^2$$
$$\text{———— of } 4x = \qquad 4n$$

Hence the increment of $x^3 + 3x^2 + 4x = 3x^2\,n + x\,(3n^2 + 6n) + n^3 + 3n^2 + 4n$.

It is therefore not neceſſary, when we proceed thus, that the propoſed function ſhould be made up of factors in arithmetical progreſſion, as in the former rule.

Again, the increment $\frac{1}{x}$ is the difference between $\frac{1}{x}$ and $\frac{1}{x + n} = -\frac{n}{x\,(x + n)}$; and in the ſame way we find the increment of $\frac{1}{x\,(x + n)} = -\frac{2n}{x\,(x + n)\,(x + 2n)}$; of $\frac{1}{x\,(x + n)\,(x + 2n)} = \frac{-3n}{x\,(x + n)\,(x + 2n)\,(x + 3n)}$; and generally the increment of

$$\frac{1}{x\,(x + n)\,(x + 2n) \ldots\ldots (x + rn)} = -\frac{(r + 1)\,n}{x\,(x + n)\,(x + 2n) \ldots (x + \overline{r + 1}\,n)}.$$

And hence, again, converſely, the integral of

$$\frac{-(r + 1)\,n}{x\,(x + n)\,(x + 2n) \ldots\ldots (x + \overline{r + 1}\,n)} = + \frac{1}{x\,(x + n)\,(x + 2n) \ldots (x + rn)}.$$

Or, more generally, the integral of $\frac{1}{x\,(x + n)\,(x + 2n) \ldots (x + rn)}$

$$= -\frac{\frac{1}{rn}}{x\,(x + n)\,(x + 2n) \ldots\ldots (x + \overline{r - 1}\,n)}.$$

This, as was before obſerved, is not the moſt general mode of conſidering the ſubject, but we are much miſtaken if it be not the moſt obvious and natural; and therefore the beſt adapted for illuſtration, and for conveying to a beginner the firſt ideas of the theory. We will now ſhew the application of the above principles to an example or two, by way of elucidation, and then proceed to a more general and extended inveſtigation of the method of increments, and its application to mathematical problems.

Ex. 1.—Let it be propoſed to find the ſum of 100 terms of the ſeries

$$1\,.\,2 + 2\,.\,3 + 3\,.\,4 + 4\,.\,5 \ldots\ldots 100\,.\,101.$$

Each of theſe terms is of the form $x\,(x + 1)$, and it is obvious that the next term to 100 . 101, that is 101 . 102, is the increment of the ſeries; or, making $100 = x$, the laſt term is $x\,(x + 1)$, and the ſucceeding one is $(x + 1)\,(x + 2)$; which is evidently the increment of the ſeries, or the difference between the propoſed ſeries in the firſt caſe, and what it becomes when x is increaſed by the common difference 1; and therefore converſely, the integral of this increment, that is, of $(x + 1)\,(x + 2)$, will be the ſum of the ſeries ſought. Now the integral of $(x + 1)\ (x + 2) = \frac{x\ (x + 1)\ (x + 2)}{3}$; and ſince x in the preſent example $= 100$, we have $\frac{100 \times 101 \times 102}{3} = 343400$ for the ſum required.

Ex. 2.—Required the ſum of n terms of the ſeries $1 . 2 . 3 + 2 . 3 . 4 + 3 . 4 . 5 +$ &c. $n\,(n + 1)\ (n + 2)$.

Here, by writing x inſtead of $n + 1$, we ſhall have for the ſucceeding term $x\ (x + 1)\ (x + 2)$, which is the increment of the ſeries, and therefore the integral of $x\ (x + 1)\ (x + 2) = \frac{(x - 1)\ x\ (x + 1)\ (x + 2)}{4}$ will be the ſum required; which, by re-eſtabliſhing the value of $x = n + 1$, becomes $\frac{n\ (n + 1)\ (n + 2)\ (n + 3)}{4} =$ the ſum of n terms.

Ex. 3.—Required the ſum of n terms of the natural ſeries of ſquares $1^2 + 2^2 + 3^2 + 4^2 + \ldots\ldots n$.

Here writing x for n, the ſucceeding term is $(x + 1)^2 = x^2 + 2x + 1 = x\ (x + 1) + (x + 1)$, which is the increment; and it conſiſts of two parts. Now the

integral of $x\ (x + 1) = \frac{(x + 1)\ x\ (x + 1)}{3}$;

integral of $x + 1 = \frac{x\ (x + 1)}{2}$.

And therefore ſince $x = n$, we have $\frac{n\ (n + 1)}{2} + \frac{(n - 1)\ n\ (n + 1)}{3} =$ the ſum required..

Ex.—Let it now be propoſed to find the ſum of the infinite ſeries $\frac{1}{1 . 2} + \frac{1}{2 . 3} + \frac{1}{3 . 4} + \frac{1}{4 . 5} +$ &c.

Here it will be neceſſary for us to conſider the ſeries as generated from the extreme term; which is 0, and therefore $\frac{1}{1 . 2}$ as its laſt term, which will therefore be the increment of the ſeries $\frac{1}{2 . 3} + \frac{1}{3 . 4} + \frac{1}{4 . 5} +$ &c.; and, conſequently, the integral of this will be the ſum of the ſeries, wanting only the term $\frac{1}{1 . 2}$. Make, therefore, $x = 2$, or $\frac{1}{2 . 3} = \frac{1}{x\ (x + 1)}$; in which caſe the increment $\frac{1}{1 . 2}$ becomes $\frac{1}{(x - 1)\ x}$, and the integral of this $= \frac{1}{x}$ (becauſe the increment is $- 1$); therefore the ſum of the ſeries, beginning at the term $\frac{1}{2 . 3}$, is $\frac{1}{2}$, to which adding the firſt term $\frac{1}{1 . 2} = \frac{1}{2}$, we have the ſum of the whole ſeries $= 1$.

This will ſerve to explain the method purſued by M. Nichole in his firſt paper, and will be uſeful as an introduction to what follows: in which we ſhall not limit ourſelves to conſidering the continual increaſe of x as conſtant as is done above; but as being variable like x itſelf; for it is under this form, that the theory of increments becomes ſo univerſally applicable to almoſt every ſpecies of mathematical inveſtigation.

Notation and Definitions.

1. As the increment of a variable quantity x is nothing more than the difference between that quantity in its firſt ſtate, and what it becomes after a certain increaſe, this difference may be properly repreſented by $D\,x$, or $\Delta\,x$; and in the ſame manner, if y be any function of a variable quantity, $D\,y$, or $\Delta\,y$, will repreſent the increment of y. And as in the fluxional or differential calculus, $\int$ is made the character of integration, ſo in the preſent inſtance, we ſhall employ it to repreſent the integral of any increment.

2. The increment of a variable quantity being, as we have obſerved above, only the exceſs of this quantity in one ſtate, over the ſame quantity in the conſecutive ſtate, it follows that if a variable magnitude x become ſucceſſively x, x', x'', x''', &c. we ſhall have $\Delta\,x = x' - x$; $\Delta\,x' = x'' - x'$; $\Delta\,x'' = x''' - x''$; $\Delta\,x''' = x^{IV} - x'''$, &c.

It may happen that an increment may be poſitive, or negative, according as the variable quantity of which it is the increment is augmented or diminiſhed, with regard to ſome other magnitude or magnitudes which we ſuppoſe to increaſe, and of which the increments are therefore neceſſarily poſitive.

3. The increments of quantities being themſelves quantities, if they be variable, we may take the increments of them, theſe are called *ſecond increments;* and if theſe ſecond increments be alſo variable, we may in like manner take the increments of theſe alſo; which are called *third increments,* and ſo on as long as the differences or increments are variable.

In all theſe caſes, the condition of the increments being variable, is neceſſary; becauſe if, in any caſe, they become conſtant, then it is obvious that the increments are 0, whether it be the firſt, ſecond, third, &c. increment that thus become conſtant or invariable.

Thus the ſeries of ſquares 1, 4, 9, 16, 25, &c. is an example of a caſe in which the ſecond differences or increments are conſtant: for this ſeries may be conſidered as generated by a variable quantity x^2; which is ſuch, that if the difference between the ſucceſſive terms be taken, they will form a ſeries of quantities in arithmetical progreſſion, and conſequently the differences of theſe differences, or the ſecond increment of x^2 will be conſtant. In the ſame manner we find the third differences of the ſeries of cubes, 1, 8, 27, 64, 125, or the third increment of x^3, is conſtant; and therefore the fourth increment $= 0$; for after any order of increments becomes conſtant, all the ulterior orders muſt, neceſſarily, become zero.

4. As $\Delta\,x$ denotes the firſt increment of any variable quantity x; ſo $\Delta^2 x$, $\Delta^3 x$, $\Delta^4 x$, &c. will repreſent the ſecond, third, fourth, &c. increments of the ſame quantity x; which expreſſions are ſufficiently diſtinct from $\Delta\,x^2$, $\Delta\,x^3$, $\Delta\,x^4$, &c. which repreſent the powers of thoſe increments; and if it be required to expreſs the power of any increment paſt the firſt, as for inſtance the nth power of the ſecond, third, &c. increment of x, that will be done thus, $\Delta^2 x^n$, $\Delta^3 x^n$, &c.

5. In ſome problems it is neceſſary to conſider a certain order of the increments as conſtant; thus, in any arithmetical progreſſion the firſt increments are conſtant. In the ſeries of natural ſquares, the ſecond increments are neceſſarily conſtant; as are alſo the third increments of cubes, &c. as we have ſeen above. But there is an in-

finite number of queſtions, in which, from their nature, it is not neceſſary that any order of their increments ſhould be conſtant: yet as we may attribute to a certain quantity whatever variation we pleaſe, providing that the variations of the other quantities depending upon the firſt be ſuch as to accord with the variation we have attributed to it; it follows, that in any problem, we may at pleaſure make any order of increments of a quantity choſen at will be conſtant; obſerving only, that the other quantities ought to vary in conſequence; and, therefore, we cannot make another order of increments alſo conſtant, unleſs, from the nature of the problem, ſome other increment has a certain ratio to that which is ſo aſſumed.

6. The whole of the method of increments conſiſts of two problems; *viz.* 1ſt. Finding the increments of all orders of any variable quantity, raiſed to any power; the product of different variable quantities; and generally of any function of variable quantities; which problem is always ſolvible, and preſents but little difficulty in any caſe; and this is called the *Direct Method of Increments.* The other problem, which is the reverſe of the preceding, is that of finding the integral of any given increment, which is frequently inſolvible; at leaſt, without infinite ſeries, or ſome other mode of approximation; and this is termed the *Inverſe Method of Increments:* which two problems we will conſider under their diſtinct heads.

Of the Direct Method of Increments.

7. Since the increment of a variable quantity is the difference between the ſums in any two conſecutive ſtates, it is obvious in general, that in order to find the increment of any function of variable quantities, we muſt ſuppoſe, that each of thoſe quantities is increaſed or diminiſhed by their reſpective increments; and ſubſtitute theſe quantities, thus changed, into the propoſed function; and from this reſult, if there be ſubtracted the original expreſſion, the remainder will be the increment ſought.

Ex. 1.—Find the firſt increment of the ſum $x + y + z$. Theſe quantities, augmented by their reſpective increments, become

$$(x + \Delta x) + (y + \Delta y) + (z + \Delta z)$$

from which ſubtracting the original expreſſion, there remains $\Delta x + \Delta y + \Delta z$, as is evident; ſince the whole increment muſt neceſſarily be equal to the ſum of each particular one.

In the ſame manner we find the increment of $x + y - z$, or $\Delta(x + y - z) = \Delta x + \Delta y - \Delta z$.

And if we had to find the increment of $a + x + y - z$, we ſhould have, conſidering a as a conſtant quantity,

$$\Delta(a + x + y - z) = \Delta x + \Delta y - \Delta z,$$

the ſame reſult as before, becauſe the conſtant quantity a has no increment, or its increment is equal to zero.

Hence it appears, that if to the ſum of any variable quantity we add or ſubtract any conſtant quantity whatever, the increment of the whole function will ſtill be the ſame.

Ex. 2. Find the firſt increment of x^m.

This is, from what is obſerved above, the difference between $(x + \Delta x)^m$ and x^m; which by the binomial theorem becomes $m\ x^{m-1}\Delta x + \frac{m(m-1)}{1 \cdot 2} x^{m-2}\Delta x^2 + \frac{m(m-1(m-2)}{1 \cdot 2 \cdot 3} x^{m-3}\Delta x^3 + \text{\&c.}\ \Delta x^m$. Thus we find the increment of x^2, or

$$\Delta(x^2) = 2x\Delta x + \Delta x^2$$
$$\Delta(x^3) = 3x^2\Delta x + 3x\Delta x^2 + \Delta x^3$$
$$\Delta(x^4) = 4x^3\Delta x + 6x^2\Delta x^2 + 4x\Delta x^3 + x^4$$
$$\text{\&c. \&c.} \qquad \text{\&c. \&c.}$$

And if the propoſed quantity, of which the increment is required, be ax^m, a being a conſtant multiplier, then it is obvious that

$$\Delta(ax^m) = \begin{cases} a(x + \Delta x)^m - ax^m = \\ a(x + \Delta x)^m - a(x^m) = \\ a[(x + \Delta x)^m - x^m] = a\Delta(x^m) \end{cases}$$

whence the increment ax^m is equal to a times, the increment of x^m.

Ex. 3. To find the firſt increment of the product xy.

Here x becomes $x + \Delta x$
and y becomes $y + \Delta y$

whence the product $= xy + y\Delta x + x\Delta y + \Delta x\Delta y$; from which, ſubtracting the original quantity xy, we have $\Delta(xy) = y\Delta x + x\Delta y + \Delta x\Delta y$.

And in the ſame way we find

$$\Delta(xyz) = \begin{cases} yz\Delta x + xz\Delta y + xy\Delta z + x\Delta y\Delta z \\ + y\Delta x\Delta z + z\Delta x\Delta y + \Delta x\Delta y\Delta z. \end{cases}$$

And in like manner may the increment of any other product be readily aſcertained.

If the product was axy, $axyz$, &c., a being a conſtant quantity, we ſhould have

$$\Delta(axy) = a\Delta(xy),\ \Delta(axyz) = a\Delta(xyz), \text{\&c.}$$

that is, we muſt find the increment as above, and multiply the reſult by the conſtant factor a.

Ex. 4.—To find the firſt increment of any quantity of the form $x(x + a)(x + 2a)(x + 3a)\ldots\ldots\ldots(x + ra)$. It is obvious that this may be referred to the preceding example, by making $x + a = u$; $x + 2a = y$; $x + 3a = z$; &c. under which ſubſtitution, the function, of which the increment is required, reduces to $xuyz$, &c. and, conſequently, $\Delta(xuyz)$ may be found as above. But if, without this ſubſtitution, we find the actual product, it is obvious that it will take the following form (where A, B, C, D, &c. repreſent conſtant quantities); *viz.*

$$x^n + Ax^{n-1} + Bx^{n-2} + Cx^{n-3} + Dx^{n-4} + \text{\&c.}$$

and hence by finding the increments of each of thoſe terms by example 2, the ſum of them will be the increment of the function propoſed. Thus,

$$\Delta\Big(x(x + a)\Big) = \Delta(x^2 + ax).$$

$$\text{Now } \Delta(x)^2 = 2x\Delta x + \Delta x^2,$$
$$\Delta(ax) = a\Delta(x) = a\Delta x;$$

whence $\Delta\Big(x(x + a)\Big) = (2x + a)\Delta x + \Delta x^2$.

And in the ſame manner

$$\Delta\Big(x(x + a)(x + 2a)\Big) = \Delta(x^3 + 3ax^2 + 2a^2x).$$

$$\text{Now } \Delta(x^3) = 3x^2\Delta x + 3x\Delta x^2 + \Delta x^3$$
$$\Delta(3ax^2) = 6ax\Delta x + 3a\Delta x^2$$
$$\Delta(2a^2x) = 2a^2\Delta x.$$

The ſum of which particular increments will be the increment of the original function propoſed: and in exactly the ſame way, the increment of any ſimilar function may be aſcertained.

Ex. 5.—To find the firſt increment of the fraction $\frac{x}{y}$.

Here we have

$$\Delta\left(\frac{x}{y}\right) = \begin{cases} \dfrac{x+\Delta x}{y+\Delta y} - \dfrac{x}{y} = \dfrac{y\,\Delta x - x\,\Delta y}{y + y\,\Delta y} = \\ (y\,\Delta x - x\,\Delta y)\;(y^2 + y\,\Delta y)^{-1} \end{cases}$$

And therefore from the expanſion of $(y^2 + y\,\Delta y)^{-1}$ into a ſeries, we have

$$\Delta\left(\frac{x}{y}\right) = \frac{(y\Delta x - x\Delta y)}{y^2} \times \left(1 - \frac{\Delta y}{y} + \frac{\Delta y^2}{y^2} + \frac{\Delta y^3}{y^3} + \&c.\right)$$

And if the propoſed fraction be effected with any conſtant factor a, the whole of the above increment muſt be multiplied by a.

Ex. 6.—To find the firſt increment of the quantity $\sqrt{(a^2 + x^2)}$.

Here it is obvious, on the ſame principles, that

$$\Delta\left(\sqrt{(a^2+x)^2}\right) = \sqrt{\left(a^2 + (x + \Delta x)^2\right)} - \sqrt{(a^2+x^2)}$$

$$\sqrt{\left((a^2 + x^2) + (2\,x\,\Delta x + \Delta x^2)\right)} - \sqrt{(a^2 + x^2)}$$

And if now we conſider theſe two expreſſions as two binomials, to be raiſed to the power $\frac{1}{2}$, it is obvious that from the developement of the firſt, there will be cancelled the firſt term, and the other terms will repreſent the increment required; and thus we have

$$\Delta\sqrt{(a^2 + x^2)} = \frac{2\,x\,\Delta x + \Delta x^2}{2\,(a^2+x^2)^{\frac{1}{2}}} - \frac{(2\,x\,\Delta x + \Delta x^2)^2}{8\,(a^2+x^2)^{\frac{2}{3}}}$$

$$+ \frac{(2\,x\,\Delta x + \Delta x^2)^3}{16\,(a^2+x^2)^{\frac{5}{2}}} - \&c.$$

Ex. 7.—Having given the equation $y^2 - a\,x + x^2 = 0$ which expreſſes the relation between the conſtant quantity a, and the two variable quantities x and y; to find the equation which ought to expreſs the relation between a, and the firſt increments of x and y.

Here we muſt ſubſtitute $x + \Delta x$ for x; and $y + \Delta y$ for y; which gives

$$(y + \Delta y)^2 - a\,(x + \Delta x) + (x + \Delta x)^2 = 0;$$

from which, ſubtracting the original equation, there remains

$$2\,y\,\Delta y - a\,\Delta x + 2\,x\,\Delta x + \Delta x^2 + \Delta y^2 = 0,$$

which is the equation required.

And in a ſimilar manner the firſt increments of any quantities whatever may be aſcertained, as alſo of any algebraical equation.

When it is required to find the ſecond, third, &c. increments of any propoſed function, it is only neceſſary to conſider the preceding order of increments as variable quantities; and we ſhall thus paſs from the firſt increments to the ſecond, from the ſecond to the third, from the third to the fourth, &c.; in the ſame manner as we paſs from the original function to the firſt increment.

Ex. 1.—To find the ſecond increment of x^2.

Here we have, in the firſt place,

$$\Delta\,(x^2) = 2\,x\,\Delta x + \Delta x^2 \text{ the firſt increment.}$$

And if now, in this expreſſion, we ſubſtitute $x + \Delta x$ for x, and $\Delta x + \Delta^2 x$ for Δx, we have

$$\Delta^2\,(x^2) = \Delta\,(2\,x\,\Delta x + \Delta x^2) = 2\,(x + \Delta x)$$
$$(\Delta x + \Delta^2 x) + (\Delta x + \Delta^2 x)^2 - (2\,x\,\Delta x + \Delta x^2)$$
$$= 2\,\Delta x^2 + 4\,\Delta x\,\Delta^2 x + 2\,x\,\Delta^2 x + \Delta^2 x^2,$$

which is the ſecond increment required.

And in the ſame way we find the third, fourth, &c. increments of a quantity or function, by ſubſtituting $\Delta^2 x + \Delta^3 x$ inſtead of $\Delta^2 x$; and $\Delta^3 x + \Delta^4 x$ inſtead of $\Delta^3 x$; and ſo on.

Remark.—If we conſider the ſecond increments as being conſtant, it adds very much to the ſimplicity of the operation; for, after having found the firſt increments, *viz.*

$$\Delta\,(x^2) = 2\,x\,\Delta x + \Delta x^2,$$
$$\Delta\,(x^3) = 3\,x^2\,\Delta x + 3\,x\,\Delta x^2 + \Delta x^3,$$
$$\Delta\,(x^4) = 4\,x^3\,\Delta x + 6\,x^2\,\Delta x^2 + 4\,x\,\Delta x^3 + \Delta x^4,$$
$$\&c.\ \&c. \qquad \&c.\ \&c.$$

we ſhall have for the higher order of increments,

$$\Delta^2\,(x^2) = 2\,\Delta x^2,\ \Delta^3\,x^2 = 0,\ \Delta^4\,(x^3) = 0,\ \&c.$$
$$\Delta^2\,(x^3) = 6\,x\,\Delta x^2 + 6\,\Delta x^3,\ \Delta^2\,(x^3) = 6\,\Delta x^3,$$
$$\Delta^4\,(x^3) = 0,\ \Delta^5\,(x^3) = 0,\ \&c.$$
$$\Delta^2\,(x^4) = 12\,x^2\,\Delta x^2 + 24\,x\,\Delta x^3 + 14\,\Delta x^4,$$
$$\Delta^3\,(x^4) = 24\,x\,\Delta x^3 + 36\,\Delta x^4,\ \Delta^4\,(x^4) = 24\,\Delta x^4,$$
$$\Delta^5\,(x^4) = 0,\ \Delta^6\,(x^4) = 0,\ \&c.$$
$$\&c.\ \&c.\ \&c.$$

Scholium.—It is eaſy to find, on the ſame principles, the ſecond increments of all ſorts of functions. For example, to find the ſecond increment of the product $x\,y$, without ſuppoſing any increment as conſtant, we muſt firſt find the firſt increment, which is,

$$\Delta\,(x\,y) = y\,\Delta x + x\,\Delta y + \Delta x\,\Delta y.$$

And ſubſtituting now in this expreſſion,

$x + \Delta x$ for x, and $y + \Delta y$ for y;
$\Delta x + \Delta^2 x$ for Δx, and $\Delta y + \Delta^2 y$ for Δy,

it becomes

$$(y + \Delta y)\;(\Delta x + \Delta^2 x) + (x + \Delta x)$$
$$(\Delta y + \Delta^2 y) + (\Delta x + \Delta^2 x)\;(\Delta y + \Delta^2 y);$$

from which, ſubtracting the firſt increment, there remains

$$\Delta^2\,(x\,y) = y\,\Delta^2 x + x\,\Delta^2 y + 2\,\Delta x\,\Delta y$$
$$+ 2\,\Delta y\,\Delta^2 x + 2\,\Delta x\,\Delta^2 y + \Delta^2 x\,\Delta^2 y.$$

And if we ſuppoſe Δx conſtant, this expreſſion reduces to

$$\Delta^2\,(x\,y) = x\,\Delta^2 y + 2\,\Delta x\,\Delta y + 2\,\Delta x\,\Delta^2 y.$$

And ſimilar methods apply in all caſes; it will, therefore, be unneceſſary to give any farther examples, except in the caſe of an exponential expreſſion, which is ſomewhat different.

Let it be propoſed, for example, to find the increment of the hyperbolic logarithm of x.

Let $y = h\,.\,l\,.\,x$; then, as x becomes $x + \Delta x$; ſo will y become $y + \Delta y$, that is,

$$y + \Delta y = h\,l\,(x + \Delta x);$$

and hence, ſince $y = h\,.\,l\,.\,x$, we have

$$y + \Delta y - y = h\,.\,l\,(x + \Delta x) - h\,.\,l\,.\,x, \text{ or}$$

$$\Delta y = h\,l\,(x + \Delta x) - h\,l\,.\,x = h\,l\left(1 + \frac{\Delta x}{x}\right).$$

Now, by the well-known logarithmic ſeries, we have

$$h\,.\,l\left(1 + \frac{\Delta x}{x}\right) = \frac{\Delta x}{x} - \frac{\Delta x^2}{2\,x^2} + \frac{\Delta x^3}{3\,x^3} - \frac{\Delta x^4}{4\,x^4} + \&c.$$

$$\text{whence } \Delta y = \Delta\,(h\,l\,x) = \frac{\Delta x}{x} - \frac{\Delta x^2}{2\,x^2} + \frac{\Delta x^3}{3\,x^3} - \frac{\Delta x^4}{4\,x^4}$$

+ &c. as required. And the higher order of increments of $h\,l\,x$ will be found as above, by taking the increments of the terms of this ſeries.

Ex. 2.—Required the firſt increment of the exponential expreſſion a^x.

Make $y = a^x$; then, when x becomes $x + \Delta x$, y will become $y + \Delta y$; whence

$$y + \Delta y = a^{x + \Delta x} = a^x \times a^{\Delta x};\ \text{but}$$
$$y \qquad = a^x \qquad = a^x:$$

$$\text{whence } \Delta y = a^x \times a^{\Delta x} - a^x = a^x\,(a^{\Delta x} - 1).$$

Now, expanding $(a^{\Delta x} - 1)$ into a ſeries, we have

$$(a^{\Delta x} - 1) = 1 + \frac{\Delta x\,(l.a)}{1} + \frac{\Delta x^2\,(l.a)^2}{1.2} + \frac{\Delta x^3\,(l.a)^3}{1.2.3} + \&c.$$

Therefore Δy, or $\Delta\,(a^x) =$

$$a^x \times \left\{\frac{\Delta\,(la)}{1} + \frac{\Delta x^2\,(l.a)^2}{1.2} + \frac{\Delta x^3\,(l.a)^3}{1.2.3} + \&c.\right\}$$

as required. And the higher order of its increments may be found by the uſual method.

Of the Inverſe Method of Increments.

8. In the inverſe method of increments, the queſtion is to find the integral, or function, from its increment being given. We muſt, therefore, examine with attention the ſteps by which we deſcend from a variable quantity to its increment; and then, by the reverſe operation, we may aſcend to the integral, when the increment is known. But this reverſe operation is attended with the very ſame difficulties as the inverſe method of fluxions, for, as in that, every fluent may be readily put into fluxions, ſo may the increment of any function be readily obtained; but it is frequently difficult, and ſometimes impoſſible to find the fluent of a given fluxion; and ſo in the method of increments, there are many caſes that will not admit of integration; we ſhall, however, give ſome of the moſt uſual and obvious rules, and which will apply to the generality of examples.

Let us firſt attend to the powers of a variable quantity x.

1. Since $\Delta x = \Delta\,(x)$; therefore, reciprocally, $\int \Delta x = x$. And if we ſuppoſe Δx as conſtant (a ſuppoſition that has place in all that follows), we ſhall have $\int \Delta x \times 1 = x$, or $\Delta x \int 1 = x$; therefore $\int 1 = \frac{x}{\Delta x}$.

2. Since $\Delta\,(x^2) = 2x\Delta x + \Delta x^2$, therefore, reciprocally, $\int (2x\Delta x + \Delta x^2) = x^2$; or, which is the ſame, $\int 2x\Delta x + \int \Delta x^2 = x^2$; whence again alſo $\int x + \int \frac{\Delta x}{2} = \frac{x^2}{2\Delta x}$; and hence, by tranſpoſition, $\int x = \frac{x^2}{2\Delta x} - \int \frac{\Delta x}{2} = \frac{x^2}{2\Delta x} - \frac{\Delta x}{2} \times \int 1 = \frac{x^2}{2\Delta x} - \frac{x}{2}$.

3. Again, ſince $\Delta\,(x^3) = 3x^2\Delta x + 3x\Delta x^2 + \Delta x^3$; therefore, reciprocally,

$\int (3x^2\Delta x + 3x\Delta x^2 + \Delta x^3) = x^3$; or, which is the ſame,

$\int 3x^2\Delta x + \int 3x\Delta x^2 + \int \Delta x^3 = x^3$; or dividing by $3\Delta x$

$\int x^2 + \Delta x \int x + \frac{\Delta x^2}{3} . \int 1 = \frac{x^3}{3\Delta x}$; whence, again,

$\int x^2 = \frac{x^3}{3\Delta x} - \Delta x \int x - \frac{\Delta x^2}{3} . \int 1$; or, which is the ſame,

$$\int x^2 = \frac{x^3}{3\Delta x} - \frac{x^2}{2} + \frac{x\Delta x}{6}.$$

We find in a ſimilar manner, by continuing to ſuppoſe Δx as conſtant, and ſubſtituting always for the quantities contained under the particular ſum their reſpective values; the following reſults for the integrals of the ſucceſſive powers of x; in which we have repeated the two preceding ones, for the ſake of uniformity.

$$\int 1 = \frac{x}{\Delta x};$$

$$\int \Delta x = \frac{x^2}{2\Delta x} - \frac{x}{2};$$

$$\int \Delta x^2 = \frac{x^3}{3\Delta x} - \frac{x^2}{2} + \frac{x\Delta x}{6};$$

$$\int \Delta x^3 = \frac{x^4}{4\Delta x} - \frac{x^3}{2} + \frac{x^2\Delta x}{4};$$

$$\int \Delta x^4 = \frac{x^5}{5\Delta x} - \frac{x^4}{2} + \frac{x^3\Delta x}{3} - \frac{x\Delta x^3}{30};$$

$$\int \Delta x^5 = \frac{x^6}{6\Delta x} - \frac{x^5}{2} + \frac{5x^4\Delta x}{12} - \frac{x^2\Delta x^3}{12};$$

&c. &c. &c. &c.

where it is only neceſſary to obſerve, that if the propoſed increment have any conſtant multiplier, the integral above found muſt have the ſame.

Cor. 1.—Hence we may find the integral of any function compoſed of the powers of x, affected with any conſtant coefficients a, b, c, &c. For in order to find the integral of ſuch an increment, it is only neceſſary to find thoſe of the different powers of x, and their ſum will be the integral required.

Ex. 1.—Required the integral of the increment $a + bx + cx^2$; conſidering Δx as conſtant.

$$\int a = a \int 1 = \frac{ax}{\Delta x}$$

$$\int bx = b \int x = \frac{bx^2}{2\Delta x} - \frac{bx}{2}$$

$$\int cx^2 = c \int x^2 = \frac{cx^3}{3\Delta x} - \frac{cx^2}{2} + \frac{cx\Delta x}{6}$$

And hence by addition,

$$\int (a + bx + cx^2) = \frac{ax}{\Delta x} + \frac{bx^2}{2\Delta x} \quad \frac{bx}{2} + \frac{cx^3}{3\Delta x} - \frac{cx^2}{2} + \frac{cx\Delta x}{6}.$$

Ex. 2.—Required the integral of $ax^4 - bx^2$, conſidering Δx as conſtant.

Here we have

$$\int ax^4 = \frac{ax^5}{5\Delta x} - \frac{ax^4}{2} + \frac{ax^3\Delta x}{3} - \frac{ax\Delta x^3}{30}$$

$$\int -bx^2 = \frac{-bx^3}{3\Delta x} + \frac{bx^2}{2} - \frac{bx\Delta x}{6}$$

the ſum of which expreſſions will be the whole increment ſought.

Cor. 2.—When it is required to find the integral of a quantity of any of the following forms, (Δx being ſuppoſed conſtant,) *viz.*

$(x + a)$
$(x + a)\,(x + 2a)$
$(x + a)\,(x + 2a)\,(x + 3a)$
$(x + a)\,(x + 2a)\,(x + 3a)\,(x + 4a)$

we arrive at them by taking the actual product of thoſe quantities, and finding ſucceſſively the increments of each of the terms: thus,

1. $\int (x + a) = \int x + \int a = \frac{x^2}{2\Delta x} - \frac{x}{2} + \frac{ax}{\Delta x}$

2. $\int (x + a)\,(x + 2a) = \int (x^2 + 3ax + 2a^2) =$

$$\begin{cases} \int x^2 = \dfrac{x^3}{3\,\Delta x} - \dfrac{x^2}{2} + \dfrac{x\,\Delta x}{6} \\ \int 3\,a\,x = \dfrac{3\,a\,x^2}{2\,\Delta x} - \dfrac{3\,a\,x}{2} \\ \int 2\,a^2 = \dfrac{2\,a^2\,x}{\Delta x} \end{cases}$$

Whence $\int (x + a)\,(x + 2\,a) = \dfrac{x^3}{3\,\Delta x} - \dfrac{x^2}{2} + \dfrac{x\,\Delta x}{6} + \dfrac{3\,a\,x^2}{2\,\Delta x} - \dfrac{3\,a\,x}{2} + \dfrac{2\,a^2\,x}{\Delta x}$.

3. Again, $\int (x + a)\,(x + 2\,a)\,(x + 3\,a) = \int (x^3 + 6\,a\,x^2 + 11\,a^2\,x + 6\,a^3) =$

$$\begin{cases} \int x^3 = \dfrac{x^4}{4\,\Delta x} - \dfrac{x^3}{2} + \dfrac{x^2\,\Delta x}{4} \\ \int 6\,a\,x^2 = \dfrac{6\,a\,x^3}{3\,\Delta x} - \dfrac{6\,a\,x^2}{2} + \dfrac{6\,a\,x\,\Delta x}{6} \\ \int 11\,a^2\,x = \dfrac{11\,a^2\,x^2}{2\,\Delta x} - \dfrac{11\,a^2\,x}{2} \\ \int 6\,a^3 = \dfrac{6\,a^3\,x}{\Delta x} \end{cases}$$

Whence by addition, we have $\int (x + a)\,(x + 2\,a)\,(x + 3\,a) = \dfrac{x^4}{4\,\Delta x} - \dfrac{x^3}{2} + \dfrac{x^2\,\Delta x}{4} + \dfrac{2\,a\,x^3}{\Delta x} - \dfrac{3\,a\,x^2}{1} + \dfrac{a\,x\,\Delta x}{1} + \dfrac{11\,a^2\,x^2}{2\,\Delta x} + \dfrac{6\,a^3\,x}{\Delta x} - \dfrac{11\,a^2\,x}{2} + \dfrac{6\,a^3\,x}{\Delta x}$; and ſo on of other ſimilar quantities.

And if it be required to find the integral of quantities of the form

$$\begin{gathered} x\,(x + a) \\ x\,(x + a)\,(x + 2\,a) \\ x\,(x + a)\,(x + 2\,a)\,(x + 3\,a) \\ \text{\&c. \&c. \&c.} \end{gathered}$$

we have in the ſame way

1. $\int x\,(x + a) = \int x^2 + \int a\,x = \dfrac{x^3}{3\,\Delta x} - \dfrac{x^2}{2} + \dfrac{x\,\Delta x}{6} + \dfrac{a\,x^2}{2\,\Delta x} - \dfrac{a\,x}{2}$

2 $\int x\,(x + a)\,(x + 2\,a) = \int x^3 + 3\,a \int x^2 + 2\,a^2 \int x =$

$$\begin{cases} \int x^3 = \dfrac{x^4}{4\,\Delta x} - \dfrac{x^3}{2} + \dfrac{x^2\,\Delta x}{4} \\ 3\,a \int x^2 = \dfrac{3\,a\,x^3}{3\,\Delta x} - \dfrac{3\,a\,x^2}{2} + \dfrac{3\,a\,x\,\Delta x}{6} \\ 2\,a \int x = \dfrac{2\,a\,x^2}{2\,\Delta x} - \dfrac{2\,a\,x}{2} \,; \end{cases}$$

the ſum of which will be the increment required.

And, in a ſimilar manner, we may find the integral to any other quantity of theſe forms.

9. *Remark.*—Before we proceed any further on this ſubject, it will be proper to attend to the correction of any integral, when from the nature of the problem under conſideration ſuch becomes neceſſary.

As the increments of any variable quantities x, and $x + a$ are both expreſſed by Δx, the conſtant part a having no increment, ſo, reciprocally, the integral of the increment Δx may be x, or $x + a$; therefore, when we have found the integral of any increment, we muſt add to it a conſtant quantity, which will be zero, if the integral needs no correction but a real quantity, poſitive or negative, in other caſes, which muſt be determined from the nature of the problem. This remark will be of conſiderable importance in what follows.

10. Let us then conſider thoſe products, of which the factors are continually increaſed by a conſtant difference; *viz.*

$$\begin{gathered} x\,(x + \Delta x) \\ x\,(x + \Delta x)\,(x + 2\,\Delta x) \\ x\,(x + \Delta x)\,(x + 2\,\Delta x)\,(x + 3\,\Delta x) \\ \text{\&c. \&c. \&c.} \end{gathered}$$

Here it is obvious that the increment of $x\,(x + \Delta x)$; or $1\,\Delta\big(x\,(x + \Delta x)\big) = (x + \Delta x)\,(x + 2\,\Delta x) - x\,(x + \Delta x)$; whence, by multiplication and ſubtraction, we have $\Delta\,\big(x\,(x + \Delta x)\big) = 2\,\Delta x\,(x + \Delta x)$.

In the ſame manner we find,

$\Delta\,\big(x\,(x + \Delta x)\,(x + 2\,\Delta x)\big) = 3\,\Delta x\,(x + \Delta x)\,(x + 2\,\Delta x)$;

And thus again,

$\Delta\big(x\,(x + \Delta x)\,(x + 2\,\Delta x)\,(x + 3\,\Delta x)\big) = 4\,\Delta x\,(x + \Delta x)\,(x + 2\,\Delta x)\,(x + 3\,\Delta x)$

and ſo on of other ſimilar products. Whence it appears, that in order to find the increment of any product of the above form, we muſt ſuppreſs the firſt factor x, and write in its place the increment Δx, effected with a co-efficient equal to the total number of factors ; all the other part of the expreſſion remaining as before.

Whence again, converſely, the integral to any increment of this form, will be found from the reverſe operation.

Thus for example,

1. $\int 2\,\Delta x\,(x + \Delta x) = x\,(x + \Delta x)$

2. $\int 3\,\Delta x\,(x + \Delta x)\,(x + 2\,\Delta x) = x\,(x + \Delta x)\,(x + 2\,\Delta x)$

3. $\int 4\,\Delta x\,(x + \Delta x)\,(x + 2\,\Delta x)\,(x + 3\,\Delta x) = x\,(x + \Delta x)\,(x + 2\,\Delta x)\,(x + 3\,\Delta x)$

and ſo on of others.

Whence, in order to find the correſponding integral to any increment of the above form, which may be repreſented generally by

$$a\,\Delta x\,(x + \Delta x)\,(x + 2\,\Delta x)\,.\,.\,.\,(x + n\,\Delta x),$$

we muſt change Δx in the firſt factor into x, and divide the whole by the number of factors ; that is,

$$\int a\,\Delta x\,(x + \Delta x)\,(x + 2\,\Delta x)\,.\,.\,.\,(x + n\,\Delta x) = \frac{a\,x\,(x + \Delta x)\,(x + 2\,\Delta x)\,.\,.\,.\,.\,(x + n\,\Delta x)}{n + 1}.$$

This part of the theory has been before conſidered in the preceding pages, in deſcribing the method employed by M. Nichole of the Academy of Sciences, publiſhed in 1717.

11. Let us now conſider thoſe fractions, the denominators of which are compoſed of factors ſimilar to thoſe above deſcribed, *viz.*

$$\frac{1}{x\,(x + \Delta x)}$$

$$\frac{1}{x\,(x + \Delta x)\,(x + 2\,\Delta x)}$$

$$\frac{1}{x\,(x + \Delta x)\,(x + 2\,\Delta x)\,(x + 3\,\Delta x)} ;\ \text{\&c.}$$

in which Δx is conſtant.

Here, by taking the differences as before, we ſhall have

$$1.\quad \Delta\left\{\frac{1}{x(x+\Delta x)}\right\}=\frac{1}{(x+\Delta x)(x+2\Delta x)}-\frac{1}{x(x+\Delta x)}$$

$$=-2\Delta x\times\frac{1}{x(x+\Delta x)(x+2\Delta x)}.$$

And in the ſame manner we find the increment, or,

$$2.\quad \Delta\left\{\frac{1}{x(x+\Delta x)(x+2\Delta x)}\right\}=-3\Delta x$$

$$\times\frac{1}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)}$$

$$3.\quad \Delta\left\{\frac{1}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)}\right\}=-$$

$$4\Delta x\times\frac{1}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)(x+4\Delta x)}$$

and ſo on of others. Whence it follows, that in order to determine the increment of any expreſſions of the above form, we muſt increaſe the denominator by one factor, and multiply the new fraction by the conſtant increment taken negatively and affected by ſuch a co-efficient, as is equal to the number of factors in the denominator of the reſulting fraction.

And hence, again, converſely, in order to find the integral correſponding to any increment of the form

$$\frac{a\Delta x}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)\,..\,(x+n\Delta x)}$$

we muſt ſuppreſs the laſt factor in the denominator, and afterwards divide the reſulting fraction, taken negatively, by the product of Δx, into the number of factors compriſed in the denominator of the ſaid fraction; thus,

$$\int\frac{a\Delta x}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)\,..\,(x+n\Delta x)}$$

$$=\frac{-a}{nx(x+\Delta x)(x+2\Delta x)(x+3\Delta x)\ldots(x+\overline{n-1}\,\Delta x)}$$

12. On the ſame principles we find

$$\Delta\left(\frac{1}{x+n\Delta x}\right)=\frac{1}{x+(n+1)\Delta x}-\frac{1}{x+n\Delta x}$$

and, therefore, reciprocally,

$$\int\frac{1}{x+(n+1)\Delta x}-\int\frac{1}{x+n\Delta x}=\frac{1}{x+n\Delta x}:$$

The integration of theſe two latter expreſſions cannot be effected ſeparately, but the difference of them is evidently equal to the algebraical fraction $\frac{1}{x+n\Delta x}$

Whence it appears, that quantities may ſometimes admit of integration, by being decompoſed into many parts; which, though they will not admit of it in their ſtate of ſeparation, may, notwithſtanding, be ſo combined with each other, that the final reſult ſhall be algebraical; a circumſtance that commonly happens in practical operations.

Examples of Integration.

13. *Ex.* 1.—Find the integral of the increment

$$\frac{3x+2\Delta x}{x(x+\Delta x)(x+2\Delta x)}.$$

This quantity admits of the following decompoſition:

$$\frac{3x+2\Delta x}{x(x+\Delta x)(x+2\Delta x)}=\frac{1}{\Delta x(x)}+\frac{1}{\Delta x(x+\Delta x)}$$

$$-\frac{2}{\Delta x(x+2\Delta x)}=\frac{1}{\Delta x}\times\frac{1}{x}+\frac{1}{\Delta x}\times\frac{1}{x+\Delta x}$$

$-\frac{2}{\Delta x}\times\frac{1}{x+2\Delta x}$: each of which parts is evidently of the form that has been inveſtigated in the preceding paragraph. By making firſt $n=0$, $n=1$, and $n=2$; thus we have

$$\int\frac{1}{x}=\int\frac{1}{x+\Delta x}-\frac{1}{x}:$$

by which means the integral of the propoſed quantity takes the following form: *viz.*

$$\frac{2}{\Delta x}\left\{\int\frac{1}{x+\Delta x}-\int\frac{1}{x+2\Delta x}\right\}-\frac{1}{x\Delta x}.$$

But the above formula gives alſo

$$\int\frac{1}{x+\Delta x}-\int\frac{1}{x+2\Delta x}=\frac{-1}{x+\Delta x}:$$

whence the whole integral is

$$\frac{1}{\Delta x}\times\left(\frac{-2}{x+\Delta x}-\frac{1}{x}\right)=-\frac{3x-\Delta x}{x\Delta x(x+\Delta x)}$$

as required.

Ex. 2.—Required the integral of the quantity

$$\frac{3\Delta x}{x(x+3\Delta x)}$$

Here we have $\frac{3\Delta x}{x(x+3\Delta x)}=\frac{1}{x}-\frac{1}{x+3\Delta x}$;

and, conſequently, the integral of the quantity will be

$$\int\frac{1}{x}-\int\frac{1}{x+3\Delta x}.$$

Now the above formula gives

$$\int\frac{1}{x}=\int\frac{1}{x+\Delta x}-\frac{1}{x}$$

$$\int\frac{1}{x+3\Delta x}=\frac{1}{x+2\Delta x}+\int\frac{1}{x+2\Delta x};$$

whence the whole integral is expreſſed by

$$\int\frac{1}{x+\Delta x}-\int\frac{1}{x+2\Delta x}-\frac{1}{x}-\frac{1}{x+2\Delta x}.$$

But $\int\frac{1}{x+\Delta x}-\int\frac{1}{x+2\Delta x}=\frac{-1}{x+\Delta x}$

by the ſame formula, and, conſequently, we have at length

$$\int\frac{3\Delta x}{x(x+3\Delta x)}=-\frac{1}{x+2\Delta x}-\frac{1}{x+\Delta x}-\frac{1}{x}.$$

Such are the elements of the direct and inverſe method of increments, and which will be found to embrace a very great number of caſes; but thoſe who wiſh for a more complete developement of the principles, cannot conſult a work better calculated to convey the neceſſary information, than the third volume of the "Traité du Calcul Differentiel, &c." par La Croix. We ſhall now conclude this article, by ſhewing the application of the foregoing theory a few examples.

Application of the Method of Increments.

14. The ſummation of ſeries, by the inverſe method of increments, is founded generally on this principle; that if we have any ſeries of quantities, as

$$a,\quad b,\quad c,\quad d,\quad e,\ \&c.$$

which are derived from each other according to ſome known law; each term may be conſidered as the increment of the ſum of all thoſe which precede it. Thus,

$$\text{let}\quad a+b+c+d+e=z$$
$$\text{and}\quad a+b+c+d+e+f=z':$$

then it is obvious, that $z' - z = \Delta z = f$; and therefore, converſely, the integral of any one of thoſe terms, conſidered as an increment, will repreſent the ſum of all the preceding part of the ſeries.

This being premiſed, we may proceed to the ſolution of the following examples.

Ex. 1. – Required the ſum of n terms of the natural ſeries

$$1+2+3+4+5+\ldots\ldots n$$

Here, by writing x inſtead of n, the term next in order will be $x+1$, which being the increment of the ſeries, we ſhall have $\int(x+1) =$ the ſum required.

Now $\int(x+1) = \int x + \int 1$; and by art. 8.

$\int x = \dfrac{x^2}{2\,\Delta x} - \dfrac{x}{2}$; and $\int 1 = \dfrac{x}{\Delta x}$.

And ſince in this caſe $\Delta x = 1$, we have

$$\int(x+1) = \frac{x^2}{2} - \frac{x}{2} + \frac{x}{1} = \frac{x^2+x}{2} = \frac{n^2+n}{2}$$

by writing again n inſtead of x, which is the ſum of n terms of the propoſed ſeries, as is alſo evident from other conſiderations.

Remark.—This example offers an eaſy illuſtration of what has been obſerved at art. 9, of the correction of an integral, which is neceſſary in many caſes, the ſame as the correction of a fluent is in the fluxional or differential calculus. Suppoſe for example, that inſtead of the preceding ſeries beginning at unity, it had commenced from any other term, as 7; the general law of formation would have been the ſame, and the increment would ſtill have had the form $x+1$; and conſequently the integral, in the firſt inſtance, would be repreſented as above; *viz.*

$$\int(x+1) = \frac{x^2+x}{2}.$$

But here a correction of the integral is neceſſary, for from the nature of the ſeries, when $x=7$, the ſum of the ſeries is 7, this being the term at which the ſeries commences; whereas, without a correction, we ſhould have the ſum $= 28$; we muſt, therefore, write

$\int(x+1) = \dfrac{x^2+x}{2} + c$; c being the correction, and ſince when $x=7$, $\dfrac{x^2+x}{2} + c = 7$; or $\dfrac{49+7}{2} + c = 7$, we find $c = -21$; after which the ſum of any number of terms of the propoſed ſeries is readily obtained. Thus for example, let $n = 16$, then the ſum of the ſeries beginning with the term 7 becomes

$$\frac{16^2+16}{2} - 21 = 115 \text{ as required.}$$

Ex. 2.—Find the ſum of the ſeries of ſquares $1^2 + 3^2 + 5^2 + 7^2 + \&c.\ n^2$.

Here the general term of the ſeries is $(x+2)^2$, and therefore the ſum required will be expreſſed by the integral of $(x+2)^2$.

Now $\int(x+2)^2 = \int x^2 + \int 4x + \int 4$; and by article 8

$$\int x^2 = \frac{x^3}{3\,\Delta x} - \frac{x^2}{2} + \frac{x\,\Delta x}{6}$$

$$4\int x = \frac{4x^2}{2\,\Delta x} - \frac{4x}{2}$$

$$4\int 1 = \frac{4x}{\Delta x}$$

And ſince in this caſe $\Delta x = 2$, we have

$$\int(x+2)^2 = \frac{x^3}{6} - \frac{x^2}{2} + \frac{2x}{6} + \frac{4x^2}{4} - \frac{4x}{2} + \frac{4x}{2}$$
$$= \frac{x^3}{6} + \frac{x^2}{2} + \frac{x}{3} = \frac{n^3}{6} + \frac{n^2}{2} + \frac{n}{3}$$

by making $x = n$.

But here again, if the ſeries do not begin at unity, it will require a correction, which will be found generally, thus: ſuppoſe the ſeries to commence at any term p; and let $x = p$, then the above formula gives the ſum of the ſeries to the term $p = \dfrac{p^3}{6} + \dfrac{p^2}{2} + \dfrac{p}{3}$, whereas it ought to be p^2; the correction therefore becomes $-\left(\dfrac{p^3}{6} + \dfrac{p^2}{2} + \dfrac{p}{3} - \dfrac{p^2}{1}\right) = -\left(\dfrac{p^3}{6} - \dfrac{p^2}{2} + \dfrac{p}{3}\right) = c$; and, therefore, the general expreſſion for any number of terms of this ſeries, between the limits p and n, will be

$$\frac{n^3}{6} + \frac{n^2}{2} + \frac{n}{3} - \frac{p^3}{6} + \frac{p^2}{2} - \frac{p}{3}.$$

Cor.—This example will alſo furniſh the ſolution of the problem, when the roots of the ſquares differ from each other by any conſtant quantity m; for it will only be neceſſary to make $\Delta x = m$, and the ſame formula will give $\int(x+m)^2 = \int x^2 + 2m\int x + m^2\int 1$

$$\int x^2 = \frac{x^3}{3\,\Delta x} - \frac{x^2}{2} + \frac{x\,\Delta x}{6}$$

$$2m\int x = \frac{2mx^2}{2\,\Delta x} - \frac{2mx}{2}$$

$$m^2\int 1 = \frac{m^2 x}{\Delta x}$$

And ſince in this caſe we have $\Delta x = m$, the ſum of theſe expreſſions becomes

$\int(x+m)^2 = \dfrac{x^3}{3m} + \dfrac{x^2}{2} + \dfrac{mx}{6} + c$, the correction; and therefore the general formula for the ſum beginning at any term p, will be

$$\frac{n^3}{3m} + \frac{n^2}{2} + \frac{mn}{6} - \frac{p^3}{3m} + \frac{p^2}{2} - \frac{mp}{6}.$$

Ex. 3.—Required the ſum of the natural ſeries of cubes $1^3 + 2^3 + 3^3 + 4^3 + \&c.\ n^3$.

Here the general term is $(x+1)^3$; and the integral of this, that is, $\int(x+1)^3 = \int x^3 + 3\int x^2 + 3\int x + \int 1$, is computed as follows:

$$\int x^3 = \frac{x^4}{4\,\Delta x} - \frac{x^3}{2} + \frac{x^2\,\Delta x}{4}$$

$$3\int x^2 = \frac{3\,x^3}{3\,\Delta x} - \frac{3\,x^2}{2} + \frac{3\,x\,\Delta x}{6}$$

$$3\int x = \frac{3\,x^2}{2\,\Delta x} - \frac{3\,x}{2}$$

$$\int 1 = \frac{x}{\Delta x}$$

And here, ſince $\Delta x = 1$, we have

$$\int (x+1)^3 = \frac{x^4}{4} + \frac{x^3}{2} + \frac{x^2}{4} = \left(\frac{x^2+x}{2}\right)^2$$

Or, by making $x = n$, the ſum required is $\left(\frac{n^2+n}{2}\right)^2$

Hence a very curious property with regard to the ſums of conſecutive cubes beginning at 1; *viz.* that this ſum is equal to the ſquare of the ſum of all their roots.

Thus, $1^3 + 2^3 = (1+2)^2$

$1^3 + 2^3 + 3^3 = (1+2+3)^2$

$1^3 + 2^3 + 3^3 + 4^3 = (1+2+3+4)^2$

&c. &c.

As to the correction in thoſe caſes that required it, it will be found as in the preceding example; as alſo the ſums of any number of cubes whoſe roots are in arithmetical progreſſion, having any common difference *m*. And the ſums of any powers whatever are attainable upon the ſame principles.

Ex. 4.—Required the ſum of any propoſed number of terms in the ſeries of triangular numbers

1, 3, 6, 10, 15, &c.

In this caſe the general term is $\frac{x(x+1)}{2}$, and it will therefore be neceſſary to find the integral of $\frac{(x+1)\,(x+2)}{2} = \frac{1}{2}\int (x+1)\,(x+2)$ but (art. 10) $= \frac{1}{2}\int (x+1)\,(x+2) = \frac{x\,(x+1)\,(x+2)}{6\,\Delta x} = \frac{n\,(n+1)\,(n+2)}{6}$ by making $x = n$, and $\Delta x = 1$.

The ſame may be otherwiſe found from art. 8; thus,

$$\tfrac{1}{2}\int (x+1)\,(x+2) = \tfrac{1}{2}\int x^2 + \tfrac{1}{2}\int 3\,x + \tfrac{1}{2}\int 2$$

$$\tfrac{1}{2}\int x^2 = \frac{x^3}{6\,\Delta x} - \frac{x^2}{4} + \frac{x\,\Delta x}{12}$$

$$\tfrac{1}{2}\int x = \frac{3\,x^2}{4\,\Delta x} - \frac{3\,x}{4}$$

$$\int 1 = \frac{x}{\Delta x}$$

And ſince $\Delta x = 1$, this ſum becomes

$$\tfrac{1}{2}\int (x+1)\,(x+2) = \frac{x^3}{6} + \frac{x^2}{2} + \frac{x}{3} = \frac{x\,(x+1)\,(x+2)}{6}.$$

And the ſums of any order of polygonal and figurate numbers may be found in the ſame manner.

Ex. 5.—Required the ſum of any number *n* terms of the ſeries

$1\cdot 2 + 2\cdot 3 + 3\cdot 4 + 4\cdot 5 +$ &c. $n\,(n+1)$

Here the general term of the ſeries is $x\,(x+1)$, it is therefore required to find the integral of $(x+1)\,(x+2)$. Firſt by art. 10. we have

$$\int (x+1)\,(x+2) = \frac{x\,(x+1)\,(x+2)}{3\,\Delta x} = \frac{n\,(n+1)\,(n+2)}{3}$$ by writing $x = n$, and $\Delta x = 1$.

The ſame may alſo be found, as in the example above, by article 8; but it is needleſs to repeat it, as it only differs from that in its conſtant factor.

We have in neither of the foregoing examples any correction, for it is obvious that when $x = 0$, the formula $\frac{x\,(x+1)\,(x+2)}{6} = 0$, as it ought to be, and therefore the integral needs no correction.

Ex. 6.—Required the ſum of any number of terms *n*, of the ſeries

$1\cdot 4\cdot 7\cdot 10 + 4\cdot 7\cdot 10\cdot 13 + 7\cdot 10\cdot 13\cdot 16 +$ &c. $n\,(n+3)\,(n+6)\,(n+9)$.

Here the general term of the ſeries is $x\,(x+3)\,(x+6)\,(x+9)$, and we have therefore to find the integral of $(x+3)\,(x+6)\,(x+9)\,(x+12)$. Now, by art. 10.

$$\int (x+3)\,(x+6)\,(x+9)\,(x+12) = \left\{\begin{array}{l} \dfrac{x\,(x+3)\,(x+6)\,(x+9)\,(x+12)}{5\,\Delta x} = \\ \dfrac{n\,(n+3)\,(n+6)\,(n+9)\,(n+12)}{15} \end{array}\right.$$

by writing $x = n$, and $\Delta x = 3$.

Ex. 7.—Required the ſum of the infinite ſeries

$$\frac{1}{1\cdot 2\cdot 3} + \frac{1}{2\cdot 3\cdot 4} + \frac{1}{3\cdot 4\cdot 5} + \frac{1}{4\cdot 5\cdot 6} + \text{\&c.}\ \frac{1}{n\,(n+1)\,(n+2)}.$$

Here the general term of the ſeries is $\frac{1}{x\,(x+1)\,(x+2)}$; and the moſt ſimple idea is now to conſider the ſeries as generated from its extremity, which is infinitely diſtant; under which circumſtance each term will be the increment of all thoſe which follow it in the above arrangement; and therefore, in order to find the ſum beginning at any term $\frac{1}{x\,(x+1)\,(x+2)}$, we have ſimply to find the integral of $\frac{1}{(x-1)\,(x)\,(x+1)}$ taken negatively, becauſe the increment *x*, that is, $\Delta x = -1$. Now, by art. 11,

$$\int \frac{1}{(x-1)\,(x)\,(x+1)} = \frac{1}{\Delta x} \times \frac{-1}{2\,x\,(x+1)} = \frac{1}{2\,x\,(x+1)},$$

becauſe $\Delta x = -1$; that is, the ſum of the above infinite ſeries beginning at any term $\frac{1}{n\,(n+1)\,(n+2)}$ is equal to $\frac{1}{2\,n\,(n+1)}$; and therefore when $n = 1$, the whole ſeries becomes $= \frac{1}{4}$.

Cor. Having thus found the ſum of the whole ſeries, we may readily find the ſum of as many terms as we pleaſe, for we have ſeen that the ſum beginning at the *n*th term from the firſt, is $\frac{1}{2n(n+1)}$; and therefore, beginning at the $(n+1)$th term, the ſum will be $= \frac{1}{2(n+1)(n+2)}$; which laſt ſum taken from the whole ſum $\frac{1}{4}$, will leave that of the firſt *n* terms, that is,

$$\text{ſum } n \text{ terms} = \frac{1}{4} - \frac{1}{2(n+1)(n+2)} = \frac{(n+1)(n+2)-2}{4(n+1)(n+2)}$$

Thus, if $n = 1$, ſum $= \frac{1}{6}$; if $n = 2$, ſum $= \frac{5}{24}$; if $n = 3$, the ſum $= \frac{9}{40}$, &c.

Ex. 8.—Find the ſum of the infinite ſeries

$$\frac{1}{1 \cdot 5} + \frac{1}{5 \cdot 9} + \frac{1}{9 \cdot 13} + \frac{1}{13 \cdot 17} + \text{\&c.} \; \frac{1}{n(n+4)}$$

Here the general term of the ſeries being $\frac{1}{x(x+4)}$; we ſhall, on the ſame principles as in the preceding example, have to find the integral of $\frac{1}{(x-4)x}$.

Now by art. 11.

$$\int \frac{1}{(x-4)x} = \frac{1}{\Delta x} \times \frac{-1}{x} = \frac{1}{4x}; \text{ becauſe } \Delta x = -4.$$

Making, therefore, $x = 1$, we have $\frac{1}{4}$ for the ſum of the whole ſeries, beginning at the firſt term. We might have added here a variety of other examples, had the limits of the article admitted of it, but ſuch as are given will be found to apply in a number of caſes; and will indicate to the intelligent reader the method of application in many others, which are reducible to ſimilar principles. It will be proper, however, before we diſmiſs this ſubject entirely, to ſay a few words on the celebrated theorem of Dr. Taylor, the learned author of this theory. This theorem may be expreſſed as follows:

Let Y′ repreſent any function whatever of the variable quantity x; then if x be increaſed by any difference Δx, the value Y, that is $Y + \Delta Y$, becomes (adopting the differential notation) $Y + \Delta Y = Y + \frac{\Delta x \, dY}{1 . dx} + \frac{\Delta x^2 \, d^2 Y}{1 . 2 . dx^2} + \frac{\Delta x^3 \, d^3 Y}{1 . 2 . 3 dx^3} + \frac{\Delta x^4 \, d^4 Y}{1 . 2 . 3 . 4 dx^4}$ &c. or, $\Delta Y = \frac{\Delta x \, dY}{1 . dx} + \frac{\Delta x^2 \, d^2 Y}{1 . 2 . dx^2} + \frac{\Delta x^3 \, d^3 Y}{1 . 2 . 3 dx^3} + \frac{\Delta x^4 \, d^4 Y}{1 . 2 . 3 . 4 dx^4}$ + &c. where the law of continuation is obvious, and requires no farther developement; it muſt, however, be remarked, that when Δx is negative, the terms of the above ſeries muſt be taken plus and minus alternately; and it will therefore be more generally expreſſed by

$$\pm \Delta Y = \frac{\Delta x \, dY}{1 \, dx} \pm \frac{\Delta x^2 \, d^2 Y}{1 . 2 \, dx^2} + \frac{\Delta x^3 \, d^3 Y}{1 . 2 . 3 \, dx^3} \pm \text{\&c.}$$

In order then to find the increment of any function of a variable quantity, we muſt take the ſucceſſive order of its fluxions, by which means all the fluxional parts in both the numerator and denominator will diſappear; and we ſhall have the value of ΔY expreſſed in terms of x and Δx; and this expreſſion will always be finite, unleſs the function be tranſcendental.

Let us propoſe the function $Y = ax + bx^2 + x^3$ to find the value of Y′, when x becomes $x + \Delta x$.

$$\begin{aligned} d . Y &= a\,dx + 2bx\,dx + 3x^2\,dx \\ d^2 Y &= 2b\,dx^2 + 6x\,dx^2 \\ d^3 Y &= 6\,dx^3 \\ d^4 Y &= 0 \end{aligned}$$

Now theſe values being ſubſtituted in the general ſeries, we ſhall have for the increment of Y,

$$\Delta Y = \Delta x (a + 2bx + 3x^2) + \Delta x^2 (b + 3x) + \Delta x^3$$

Again, given $Y = ax + bx^2 - cx^3 + x^4$, to find the increment of Y.

$$\begin{aligned} d Y &= a\,dx + 2bx\,dx - 3cx^2\,dx + 4x^3\,dx \\ d^2 Y &= + 2b\,dx^2 - 6cx\,dx^2 + 12x^2\,dx^2 \\ d^3 Y &= - 6c\,dx^3 + 24x\,dx^3 \\ d^4 Y &= + 24\,dx^4 \\ d^5 Y &= 0 \end{aligned}$$

Whence making theſe ſubſtitutions in the general theorem, we have

$$\Delta Y = \begin{cases} \Delta x(a + 2bx - 3cx^2 + 4x^3) + \Delta x^2 (b - 3cx + 6x^2) \\ + \Delta x^3 (c + 4x) + \Delta x^4. \end{cases}$$

Theſe examples will explain the method of applying the theorem to any caſe that may ariſe, it being as univerſal in its application in the theory of increments, or differences; as the binomial theorem is in the expanſion of roots and powers; but, like the latter, it was left by its author without demonſtration: it has, however, received many ſince from ſeveral able mathematicians, though there is no one of them perhaps that is quite ſo ſatisfactory as might be wiſhed; Maclaurin's reſts upon the fluxional calculus, which it would be deſirable not to introduce, if it could be obtained from more evident and obvious principles. Another demonſtration of this theorem, and which is conſidered the moſt ſatisfactory of any that has yet appeared, is given by l'Huilier of Geneva, in his work entitled "Principiorum calculi diff. et integr. expoſitio elementaris," in 4to. publiſhed in 1795.

INCROACHMENT, in *Law*. See ACCROCHING.

INCRUSTATION, the lining or coating of a wall, either with gloſſy ſtones, ruſtics, marble, pottery, or ſtucco-work; and that either equably, or in panels and compartiments.

INCRUSTATION, in *Natural Hiſtory*, is one of the modes in which organic remains are preſerved in the earth: the petrifying or incruſting matter, forming ſo thin a coat or cruſt around the extraneous foſſil, that its external form is nearly preſerved on the ſtony incruſtation. Mr. William Martin claſſes theſe among the artificial genera of reliquia; and obſerves, "Outlines," p. 177, note, that "the common calcareous incruſtations of our rivers, &c. have been ranked as petrifactions; but, with more propriety, may be conſidered as incipient matrices." If the coat of mineral matter be too thick to exhibit externally the exact figure of the foſſil which it covers, ſuch are called by this author ſub-incruſting matrices, of which ironſtone nodules incloſing leaves of plants, &c. are well-known examples. The petrifying ſprings of Derbyſhire, (for a liſt of which, ſee Mr. Farey's Report on that county, vol. i.) and other calcareous diſtricts, are well known for the curious and whimſical incruſtations which are there in a ſhort time produced.

INCRUSTED, or INCRUSTATED *Column*. See *Incruſtated* COLUMN.

INCUBATION, in *Comparative Anatomy*, is the term applied to the conduct of moſt birds in reſting or ſitting upon their eggs, in order to communicate to them the neceſſary degree of warmth for the excitement of their internal parts, and the developement of the fœtus.

The phenomena produced by incubation are ſo intereſting, on account of their exhibiting in a palpable manner the progreſs of fœtal exiſtence, that they have been ſtudied by almoſt every reſpectable phyſiologiſt. Writings have been left upon this ſubject by Ariſtotle, Hippocrates, Fabricius ab Aquapendente, Aldrovandus, Coiter, Veſling, Harvey, Langly, Schrader, Theod. Aldes, Stenon, Needham, Malpighi, Maitre Jan, Haller, Hunter, Monroe, &c. beſides ſome later obſervations by Blumenbach, Leveille, and other continental anatomiſts. Notwithſtanding the labours of ſo many eminent men, ſome of the moſt important points in the hiſtory of incubation remain ſtill undetermined. The beſt treatiſes are thoſe of Malpighi, Maitre Jan, and Haller, but even in theſe authors there are many errors to correct, and, except ſome detached figures that have been publiſhed to illuſtrate particular parts of this ſubject, we do not poſſeſs any tolerably good plates.

The deficiency and doubts that ſtill remain, with reſpect to ſeveral parts of the hiſtory of incubation, prove how difficult it is to inveſtigate the ſubject.

The membranes of the egg, and the organs of the chick, are in general ſo tender, that they do not admit of being eaſily or ſatisfactorily examined; and when prepared by immerſion in ſpirits, acids, or other aſtringent liquors, their natural appearances and connections are much obſcured.

The progreſs in the growth of the membranes is found to be in many circumſtances unlike what would be expected, and what it appears to be; and the attachments of the membranes to each other are extremely intricate and perplexing. This part of the anatomy of the incubated egg, therefore, principally requires improvement. In the following article we have endeavoured to ſupply, by our own obſervations, what was deficient in the hiſtory of incubation, but, we muſt confeſs, not with as much ſucceſs as we could wiſh; there are ſeveral anatomical points upon which we are obliged to ſpeak doubtfully, and we have not been able to ſatisfy ourſelves reſpecting the uſes attributed to ſome of the parts of the incubated egg, although we believe others will be found to be elucidated by the experiments we have made, and which are here related.

Moſt writers upon incubation, appear to us to have paid too much regard to the dates or periods at which they have obſerved the different events of incubation to occur. Much exactneſs with reſpect to dates is not of material conſequence, and if it were, it is not practicable, for the progreſs of incubation depends ſo much upon climate, ſeaſon, and the diligence of the parent, with many accidental circumſtances, that hardly any two eggs agree preciſely in their ſtate of growth, at any given period of incubation: we are not, therefore, to wonder at the difference amongſt writers upon this ſubject with reſpect to chronology.

The proper heat for the hatching of hens' eggs is 104° of Fahrenheit; to which degree the ſurface of the body of the hen will raiſe the thermometer when ſhe ſits upon her eggs. In thoſe birds that do not ſit conſtantly, but truſt to the heat of the ſun, the temperature of the eggs is probably below 104 degrees.

The full period of incubation by the *hen*, in this country, is well known to be 21 days. In warmer climates it is ſaid to be a day or two leſs. The periods of incubation vary much in different ſpecies of birds: we introduce the following table, which has been compiled from different authors by count Morozzo, in a letter from him to Lacépède, to ſhew the periods of incubation compared with thoſe of the life of certain birds.

Names of Birds.	Periods of their Incubation.	Duration of their Life.	Authority.
	Days.	Years.	
Swan	42	about 200	Aldrovandi.
Parrot	40	—— 100	Wolmaer.
Gooſe	30	80 or more	Willoughby.
Eagle	30	period of life not known.	
Buſtard	30		
Duck	30		
Turkey	30		
Peacock	26 to 27	25 to 28	Ariſtotle and Pliny.
Pheaſant	20 — 25	18 — 20	A Treatiſe on Pheaſants.
Crow	20	100 or more	Heſiod.
Nightingale	19 to 20	17 to 18	Buffon.
Hen	18 — 19	16 — 18	Buffon.
Pigeon	17 — 18	16 — 17	Several obſervations.
Linnet	14	13 — 14	Willoughby.
Canary	13 to 14	13 — 14	A Treatiſe on theſe Birds.
Goldfinch	13 — 14	18 — 20	Buffon.

Crane and *heron*, as well as *oſtrich*, hatch their eggs chiefly by the heat of the ſun. Journ. de Phyſique Ventos. an. 10.

The uſual mode of examining the progreſs of incubation, is to gently fracture the ſhell, and pick it carefully off in pieces with a pair of forceps. This ſhould be done at the large end, as it is there the changes of incubation commence, and at all periods it will be found the moſt convenient place for breaking the ſhell, on account of the air-cell being interpoſed between it and the fluids of the egg. For particular purpoſes other modes of preparation muſt be employed. If it be our object to ſtudy the formation of the membranes, theſe muſt be ſeparated from the humours, and after being cleanſed by being paſſed through ſeveral waters, they are to be floated in weak ſpirits over a blue paper, or ſome other dark coloured ſubſtance. The ſtrongeſt ſpirits, diſtilled vinegar, or a ſolution of alum, are neceſſary to render the organs of the fœtus ſufficiently plain for examination. The only uſe of boiling the contents of the egg, is to ſhew the relative ſituation and magnitude of different parts.

In many obſervations, it is neceſſary to magnify by glaſſes the ſubjects of inveſtigation; we would however recommend, that the ſight be only aſſiſted by the ſingle lens. When a higher power is employed it is liable to deceive.

After the egg has been ſat upon for 12 *hours*, the quantity of *air* contained between the two layers of the membrane that lines the ſhell, is found to be a little increaſed.

No evident change is yet to be obſerved with reſpect to the bulk or conſiſtence of the *humours*.

The *white* ſpot on the ſuperior ſurface of the yolk, which contains the *cicatricula* of the ancient anatomiſts, or the *follicle* of Haller, is now ſomewhat enlarged. There appears, in its interior, a ſmall white body of an elongated and indiſtinct figure, which is ſurrounded by a line of a deep yellow or greeniſh colour. If this part of the membrane be removed and examined with a lens on the under ſurface, after being a ſhort time immerſed in ſpirits or vinegar, it will be diſcovered that the elongated white body is the rudiment of the *fœtus*, which is already incloſed in the *amnios*. The greeniſh appearance would ſeem to depend partly upon the exiſtence of the amnios, and partly upon a depreſſion on the ſubſtance of the yolk, which is the origin of the bed of the chick. We cannot determine whether this depreſſion contains a fluid or not. The part of the white ſpot which ſurrounds the depreſſion that contains the fœtus, is occaſioned by the ſubſtance of the yolk having a peculiar organization. At that point it is white, and has a curdy or coagulated appearance. Malpighi believed that he could diſcern the fœtus as early as the ſixth hour, and even before the egg had been ſat upon; but moſt other obſervers have not been able to ſee any appearance, which they thought deſerved to be conſidered as the fœtus, before the 12th hour. It is, however, probable, that the embryo of the chick is formed after impregnation, although from its extreme tenderneſs and obſcurity of figure, it cannot be detected until it is a little developed by incubation.

The *amnios* appears to be coeval with the chick.

The *rings* or *circles* (*halones*) that ſurround the cicatricula, are now ſomewhat enlarged, and more defined in their outline. They alſo aſſume a little of an oval figure. The external circle is undulating, or forms waves, through which the colour of the yolk appears. Maitre Jan deſcribes four halones, Haller only three; we have found the number vary. This appearance of circles is not eaſily accounted for. We have thought it aroſe from the ſeparation of the membranes into their proper layers.

Firſt Day, or after 24 *Hours.*—Upon opening an egg at this period, it is perceived that the ſpace formed for the admiſſion of air between the layers of the external membrane is a little more enlarged.

The *external white* appears ſcarcely diminiſhed; it is fluid and tranſparent, and runs out at the opening if the egg be inclined to that ſide.

The *yolk* is found to float higher in the principal white than before incubation, and appears a little flattened upon the upper ſurface.

The *halones* are more extended, particularly the outer one. The internal one has acquired a little of a heart-ſhape, and is ſurrounded by a more defined line of a greeniſh colour, which is the firſt appearance of the outline of the veinous area. There are alſo ſome faint and imperfect traces of green veſſels, or rather elongated points, to be detected in different parts of the ſpace incloſed by this line, which are the rudiments of the veſſels that are to compoſe the area.

The *amnios* is well formed, and compoſed of two circles which unite two ſtraight lines, reſembling the figure of a peſtle.

The *fœtus* has a more determined figure; it is larger at both extremities than in the middle; but the end which correſponds to its head is larger than the other, and forms an oval maſs. Maitre Jan ſtates that if an egg, after being under the hen for 24 hours, be put into water, it will float with the ſmall end downwards, which is a proof that a part of its fluids is loſt, and replaced by the admiſſion of air into the air-cell at the great end of the egg.

After 36 *hours* we have found the greeniſh line, already mentioned, to have ſtill more plainly the appearance of a veſſel. It encompaſſes a larger area, and aſſumes more completely the contour of a heart. The greeniſh points alſo now are continued into each, and put on the appearance of veſſels, which are moſt numerous next the circumference of the area, but preſent no evident connection with the fœtus. Some of theſe veſſels are ſeen to contain red blood, more particularly thoſe which paſs between the head of the chick and the upper part of the veſſel in ſhape of a heart. In ſome eggs, at this period, we have found theſe red veſſels approach the chick but not join it: in others they were collected by a ſingle branch, which paſſed behind the head of the chick. This branch Leveillé has called the meningo-cardiac vein, and others the vena aſcendens. There is conſiderable variety with reſpect to the period at which red veſſels begin to appear. We have ſeen them before the 36th hour, but oftener, perhaps, not before the 40th, or even later. Authors differ extremely on this point. Malpighi repreſents the commencement of the veſſels at the 30th hour (Append. figs. 18 and 19.), and even delineates them at the 12th hour. (Epiſt. 1. fig. 5.) Stenon obſerved them at the 71ſt hour; Veſling at the 43d, but ſaw the points at the 42d hour. Aldrovandus found them the third day. Maitre Jan deſcribed the firſt appearance of veſſels at the 38th hour, and repreſented them diſtinctly formed, and carrying red blood at the 44th hour. (P. 53 and 58, and fig. 10.) Haller noticed ſome reddiſh points at the 36th hour, and to the 48th, but did not perceive perfect red veſſels before the end of the third day. Memoire 2d ſur la Formation du Cœur dans le Poulet, &c. p. 23.

Theſe contradictory accounts depend in ſome degree upon their authors not having ſufficiently attended to the exiſtence of colourleſs points and veſſels before the formation of red blood.

Haller ſtates, that he obſerved, at 31½ hours, the head of the *fœtus* to have the appearance of being ſplit, which he attributed to the veſicles of the brain having a ſmall degree of opacity, whilſt the membranes compoſing the cranium were ſo tranſparent as to be ſeen through. Malpighi alſo repreſented this appearance. We have not noticed it.

Haller likewiſe deſcribes the head of the chick to begin to form at a right angle with the tail at the 40th hour.

After 48 *hours, or two days*, the external *halones* occupy a conſiderable extent upon the ſurface of the yolk, and become fainter in their appearance.

The *liquid* or *external white* is ſomewhat diminiſhed.

The *principal white* begins to ſubſide to the bottom and ſmall end of the egg.

The *yolk-bag* appears flatter upon the upper ſurface, and its contents are a little more fluid than before incubation.

The *chalazæ*, which were originally ſituated at the two poles of the yolk-bag, are now found ſomewhat below them, and conſequently rather nearer to each other.

The *vaſcular area* (*figure veineuſe* of Haller) is now in general completely formed with colourleſs and red veſſels. The number of the latter is very variable. We have found them at this period in very different ſtates of advancement, but always diſcoverable by the greeniſh veſſels which precede them. The area has very perfectly the figure of a heart, except that the part correſponding to the baſis is formed by the outline of the two ſides being conſiderably curved before their junction in the middle, at which place the outline of the area forms a pointed projection downwards, which nearly reaches to the head of the fœtus. It is this part of the area which receives the branches of the meningo-cardiac vein already mentioned. The veſſels are now alſo connected with the chick by means of their principal trunks.

The *pulſation* of the *heart* is evident at this period, and even in ſome hours before, according to Maitre Jan's obſervations. It appears to be produced by the alternate contraction and dilatation of two or ſometimes three veſicles. This appearance is the *punctum ſaliens* of the older anatomiſts, and has been commonly, but erroneouſly, reputed the firſt action of life.

One mode of preparing eggs for examination is to remove a portion of the membranes including the fœtus and vaſcular figure around it, and having waſhed off any pieces of the yolk that may adhere to them, immerſe them for a ſhort time in ſtrong ſpirits or diſtilled vinegar, by which means the pulpy ſubſtance that compoſes the chick is rendered opaque and viſible, and the ſtructure of the membranes more diſtinguiſhable.

If this ſtep be taken with the egg at the preſent period, or even before it, a fine gloſſy tranſparent membrane will be found upon the external ſurface of the yolk-bag, which is very readily detached, leaving the fœtus and the vaſcular area beneath. This membrane, we conceive, is the ſame which, ſtrengthened by the veſicula umbilicalis, becomes the one which at laſt entirely envelopes the contents of the incubated egg.

The membrane, containing the *vaſcular area* at the ſecond day, may be diſtinguiſhed to be compoſed of two layers; the external is ſmooth, and receives the veſſels; the internal is a little thickened and ſpongy. The remaining portion of the yolk-bag is not ſeparable into different layers. From hence it would appear that the diviſion into layers is the conſequence of veſſels being diſtributed to the membrane.

The *amnios* is now found a little larger, and the tranſparent fluid with which it is filled in greater quantity. The ſuperior circle alſo, or that which incloſes the head of the chick, is larger than the lower.

The *fœtus* has altered its ſhape a little. The head has acquired ſomething the figure of the ace of clubs, the anterior prominence of which correſponds to the noſe and mouth; and the two other projections are the veſicles containing the brain in a very ſoft pellucid ſtate. Maitre Jan ſtates that the eyes alſo are viſible at this period. (P. 77.) Haller did not ſee the eyes before the 51ſt hour, at which time they had not any colour, and were merely diſtinguiſhable from the other parts of the head, by their prominences and ſituation. Sect. xii. Second Memoir.

The *heart*, before the chick is removed from the membranes, and rendered opaque by immerſion in ſpirits, appears to be ſituated on the outſide of the body, and the pulſating points ſeem unconnected with each other; but upon a cloſe examination it is ſeen that the heart is not uncovered, although, from its projection, and the natural tranſparency of the parietes of the cheſt, it had every appearance of being ſo. The heart altogether reſembles a horſe-ſhoe in form, or a portion of a circle, of which the convexity is turned forwards, and the limbs backwards, one being directed to the upper part of the cheſt, and the other to the lower. The heart at this time conſiſts of an auricular canal, a ventricle, and a bulbous enlargement belonging to the aorta. The two laſt are the ſalient points, and when the chick is ſo far advanced that the auricle is formed and pulſates, which is ſometimes the caſe at the 48th hour, there are three ſalient points to be ſeen. Maitre Jan deſcribes four ſalient points, and ſuppoſes that they are the rudiments of the two ventricles and two auricles of the heart. At other times, he ſays he has ſometimes ſeen but three pulſating points, or perhaps two, or only one. Haller, who paid particular attention to the developement of the heart of the chick, contradicts Maitre Jan's account. At the 48th hour he could diſcover but two ſalient points; at the 50th hour he ſaw three, but on no occaſion more than that number. He ſuppoſes that when there are two ſalient points the auricle does not pulſate, and when only one the bulb of the aorta is without motion. Memoire 1. p. 83.

The End of the third Day, or Seventy-two Hours.—This is a very important period in the hiſtory of incubation.

The ſeparation of the layers of the external membranes for the admiſſion of air continues to increaſe.

The *halones* are ſcarcely to be diſcovered. The *yolk* is more extended, and the *white* continues to gravitate to the lower parts of the egg.

The *vaſcular area* is now generally found to be perfected with red veſſels. The contour of the area is more extenſive, particularly in the tranverſe direction. The diameter being now about an inch and a quarter, it has therefore leſs the ſhape of a heart: the pulſation of the three veſicles, and diſtribution of the blood-veſſels, are very clearly ſeen through the tranſparent membrane which covers them.

The *amnios* begins to aſſume the figure that it is afterwards to poſſeſs. The two circles which encompaſs the head and the tail of the fœtus become enlarged, principally on the fore-part, or the ſide next the right-hand of the obſerver; but the ſac is a little contracted on the ſame ſide oppoſite to the umbilicus of the chick, thus tending, in a degree, to give the amnios the form of a kidney.

The *fœtus* has a curved poſition forwards, and its body appears larger in proportion to its head, than on the preceding day.

We have forborne to deſcribe particularly the *heart* and *blood-veſſels* of the chick and area until the preſent period, when they are more diſtinctly ſeen.

In order to diſcern perfectly theſe parts, the membrane including the fœtus and vaſcular area ſhould be removed from the yolk-bag, floated in clear water, and examined with a lens. The vaſcular area contains four or five principal veinous branches, which ramify upon the membrane, and produce a very cloſe and intricate net-work towards the circumference of the area. Theſe branches appear, when the chick is in the natural ſituation, to be ſo many diſtinct trunks. Two of them are ſeen to come from the ſides of the chick, a third from under the tail, and one, or ſometimes two, branches from under the head of the chick. The two firſt are commonly called the *umbilical* veſſels, as they come out of the chick at the umbilicus: they would, perhaps, with more propriety, be called meſenteric veins, as we have much reaſon for ſuppoſing that they are the ſame which are ſo plainly branches of the meſenteric vein in the latter ſtages of incubation. At the preſent period they terminate in the vein which correſponds to the vena cava and vena portæ. Both the branches which emerge from under the tail and head of the fœtus are found to be given off from the umbilical veins juſt outſide the body of the chick. This origin is concealed from view until the lower ſurface of the membranes and chick are carefully examined. Several anatomiſts ſeem to have publiſhed errors with reſpect to the ſuperior or aſcending veſſels of the vaſcular area. They are often deſcribed as diſtinct branches, which are loſt on each ſide of the notch or chink, which has been already mentioned to exiſt during the firſt days of incubation in the contour of the vaſcular area. They were, therefore, ſometimes ſuppoſed to be ſeparate veſſels. Langly repreſented them to be at firſt diſtinct branches, which united at the 61ſt hour; but Malpighi, Maitre Jan, Haller, &c. ſtate that theſe two branches always unite into one behind the head of the fœtus when they do not ſooner. Malpighi, Maitre Jan, and others, however, repreſent this veſſel as coming from the heart: Maitre Jan even ſuppoſes it may be the aſcending aorta. Our obſervations, nevertheleſs, lead us to agree with Haller reſpecting this veſſel, who ſtates it to be a branch of the umbilical vein. It is this veſſel to which Leveille has given, as we conceive improperly, the name of *meningo-cardiac vein.*

The veſſel which forms the contour of the vaſcular area has been commonly deſcribed as a ſingle vein: Malpighi, however, repreſented it as being compoſed of an intertexture, or plexus of the ultimate branches of the veins which are ſpread over the vaſcular figure. There appears to be ſome foundation

tion for both theſe accounts, according to our obſervations: thus we have ſometimes ſeen with a lens the appearance deſcribed by Malpighi, and at the ſame time the ſingle trunk nearly tranſparent from wanting red blood, and enveloped and concealed by the intricate and cloſe plexus formed by the extremities of the veins of the external part of the area. We believe, however, that there is in every caſe originally a ſingle veſſel which makes the outline of the veinous figure or area, and which exiſts previouſly to the veſſels which communicate with the chick. It is not uncommon to find this veſſel deficient at ſome parts of the circumference of the area, more eſpecially at the ſuperior part, where the outline makes the pointed projection inwards towards the head of the chick. Sometimes a vein is ſeen to paſs acroſs the chink formed by the outline at this part.

The arteries which go to the vaſcular area bear no proportion to the veins. They are ſo ſmall that they are not eaſily ſeen, and even have been by ſome ſuppoſed not to exiſt. The left umbilical artery is in general much more conſiderable than the right; indeed we have ſometimes doubted whether the latter exiſted or not. They accompany the veins in their courſe, but are not ſuppoſed to have any immediate connection with the veſſel which forms the contour of the area. Beſides the ſmall ſize of the arteries at this period of incubation, they are difficult to diſcover on account of all the blood-veſſels of the egg carrying blood of the ſame colour. During the firſt days the blood is a bright ſcarlet, or poſſeſſes an arterial character. The parts compoſing the heart of the chick, although formed ſeveral hours before, are now particularly evident. The vein, which in the firſt periods conveyed the blood from the vaſcular area to the horſe-ſhoe dilatation correſponding to the heart, is now ſeen to be the vena cava, or rather it ſhould be conſidered as the vena portæ and cava together. At the ſuperior part of this vein a dilatation is formed, which is prolonged tranſverſely forwards, and inclines a little downwards. This dilated part, in which the vena cava ends, is the origin of the ſingle auricle of the heart of the fœtus, and is the firſt veſicle in order which is ſeen to pulſate.

Towards the end of the third day, according to Haller, the enlargement of the head of the vena cava becomes greater, and is diſtinguiſhed from the reſt of the vein by a whitiſh-coloured interval; it is ſtill, however, but a ſingle cavity: its greateſt diameter is acroſs from the right to the left ſide of the fœtus. The canal which conveys the blood from the auricle into the ventricle (*le canal auriculaire* of Haller), exiſts, as already mentioned, before the vena cava becomes dilated to form the auricle, at which time it might be conſidered as the continuation of the cava. This canal is, therefore, one of the firſt formed parts of the heart. It is moſt long and ſlender when it firſt appears, and gradually contracts in length, until it is loſt in the ſubſtance of the heart. It is ſmalleſt where it ariſes from the auricle, and wideſt where it opens into the ventricle: its diameter, however, is always leſs than that of the latter. It enters the ventricle on the left ſide, for which purpoſe it deſcends a little, and therefore croſſes the aorta, which ariſes from the ventricle on the right ſide and aſcends backwards. There ariſes from the decuſſation of theſe two veſſels the appearance of a kind of knot, and the auricular canal ſeems to double upon itſelf, in order to be continued with the aorta in the oppoſite and concealed ſide of the knot.

When the auricular canal is viewed on the right ſide, its extremity is concealed, and the manner in which it opens into the ventricle cannot be perceived: it ſeems rather as if ſeparated from the ventricle by a line which is the border of the heart. But if it be viewed on the left ſide, there is no difficulty in diſcovering its communication with the ventricle.

The *ventricle* is a ſingle cavity during the firſt four or five days of incubation; or rather, the left ventricle exiſts only at that period. When the two ventricles make their appearance, it is in conſequence of the right ventricle being added to that which had already been formed. The left, or ſingle ventricle, ariſes out of the ring-ſhaped veſſel, which conſtitutes the firſt appearance of the heart, and probably is the firſt point which pulſates. It is an oval veſicle, with tranſparent parietes in the commencement; but it ſoon acquires more of a conic figure, with a pointed apex, and greater thickneſs and muſcular power: it is, however, very nearly oval at the preſent period.

The *aorta*, as already mentioned, is coeval with the firſt appearance of the heart, and exiſts before the formation of the auricle. It is then very long, and its arch is much greater in proportion to the length than in the ſucceeding periods of incubation, as in the adult bird. It makes an extenſive curve backwards, in order to enter the cheſt, immediately under the head, and compoſes a conſiderable part of the ring which repreſents the heart. On the left ſide this artery appears as if cut off by a line which terminates the heart. The auricle, when formed, is ſurrounded by the arch of the aorta, which is ſuperior, and more forwards.

A few hours after, the part of the aorta which appears to be outſide the cheſt, becomes ſhorter, and ſome inequality is perceived in its diameter. The part of the aorta, which immediately ariſes from the ventricle, is more contracted than any other; and the wave of blood which is ſeen to paſs through it is very ſlender. Haller gives the name of the *ſtrait* (*le détroit*) to this part.

The next part of the aorta is a dilatation, to which Haller has given the name of the *bulb* of the aorta. This portion of the veſſel, as already mentioned, conſtitutes one of the pulſating points, and is ſeen to beat even before the auricle. The bulb of the aorta has been miſtaken by Malpighi for the left ventricle, which, conſidering its lively and early pulſation, was not unnatural. He likewiſe was led by the ſame error to take the ſingle ventricle, which is actually the left for the right, or pulmonary ventricle of the heart.

The third portion of the aorta is cylindrical; its direction is changed, and it repreſents with the preceding a point or beak. It is ſmaller than the bulb, but larger than the branches which go to produce the dorſal aorta. Haller calls this part the *bec de l'aorte*.

Soon after the preſent period, and before the end of the fourth day, there are branches ſeen to ariſe from the beak of the aorta, in order to form the dorſal portion of that veſſel.

The three parts which compoſe the heart of the fœtal chick pulſate ſo rapidly, when examined immediately after the egg is opened, that the eye cannot follow them; but in proportion as the chick becomes cold and feeble, the intervals between the pulſations become longer. The pulſations may be thus gradually reduced to fifteen, to ten, to five, or two, or at laſt even to but one in a minute; nevertheleſs, the celerity with which each contraction is performed is ſcarcely diminiſhed.

When the pulſations of the heart are rendered ſufficiently ſlow to be counted, they are perceived to follow each other in a regular ſucceſſion. The auricle always beats the firſt of the three veſicles. In its ſyſtole the point deſcends, and the ſides are approximated; it ſcarcely ever appears to expel entirely the drop of blood it contains, and therefore it retains almoſt conſtantly a degree of red colour.

The wave of blood which proceeds from the auricle appears to vaniſh, as one cannot ſee its courſe into the ventricle unleſs the heart be beheld obliquely from above: then the blood will be ſeen to paſs along through the auricular canal, which, as before obſerved, is concealed by the ventricle.

The contraction of the ventricle ſucceeds to that of the auricle: it approximates its ſides, and becomes narrower and ſhorter. The ventricle frequently becomes quite pale during its contraction, owing to the entire expulſion of its contained blood.

After the contraction of the ventricle follows that of the bulb of the aorta, which pulſates as quickly and perfectly as the ventricle itſelf. It empties itſelf completely at each contraction, and therefore appears quite pale at theſe moments.

The pulſatory movement terminates at the origin of the three veſſels which go to form the dorſal aorta, and this veſſel declines very much in bulk oppoſite to the umbilicus; the branches which go to ſupply the inferior parts of the fœtus being very inſignificant.

The different *membranes* become more diſtinct at the end of the third day than they were before. At this period alſo the firſt appearance is ſeen of that remarkable membrane, which is called by ſome *allantois*, and by others *veſicula umbilicalis*.

When a portion of the membrane is removed containing the vaſcular area and the chick, and waſhed and ſpread out in clear water, it is found to contain four layers. The firſt is thin, tranſparent, and ſhining, and reſembles that which forms the yolk-bag before incubation. It very readily ſeparates from the other layers. The ſecond is alſo tranſparent, and ſtill thinner than the firſt, but is more adherent to thoſe underneath it. The third is the membrane in which the blood-veſſels are diſtributed that form the vaſcular area; and the fourth is the internal or ſpongy membrane of the yolk-bag. The third membrane ſeems to grow with the vaſcular area, by which it appears to be bounded: the internal membrane of the yolk-bag is at this period a little ſpongy or villous at every part, but much more ſo under the vaſcular area than at any other place.

The chick incloſed in the amnios is ſituated between the two firſt and two laſt of theſe membranes.

The *veſicula umbilicalis*, when firſt diſcovered, makes its appearance as a ſmall ſpherical tranſparent bag, which projects out of the opening into the abdominal cavity of the chick, that is left by the reflection of the amnios inwards. At this period, and for ſome time afterwards, it is diſtended by a clear fluid.

The end of the fourth day, or ninety-ſix hours, the appearance of *halones* is in general no longer to be perceived.

The *vaſcular area* is ſo much extended that it occupies near the half of the ſuperficies of the yolk: the outline has no remains of the heart ſhape, but has aſſumed an oval figure, the greateſt diameter of which is in the tranſverſe direction of the chick.

The *air-cell* continues to enlarge at the great end of the egg.

The *external* or *liquid white* appears to be all conſumed.

The *principal white* is chiefly to be found in the lower parts of the egg, and when poured out is ſeen to adhere a little to the internal layer of the membrane of the ſhell at the ſmall end of the egg.

The *yolk-bag* is ſtill flatter in its figure than before, and its contents are evidently more fluid than they were previous to incubation.

The *chalazæ* continue to approach each other below the poles of the yolk-bag.

The *amnios* is conſiderably increaſed, contains more fluid, and forms a deeper bed for the chick on the membrane of the yolk-bag.

The *veſicula umbilicalis* has made a rapid progreſs ſince the end of the third day. It now projects conſiderably beyond the fœtus. It appears flatter, and leſs full of fluid than at firſt; and at this period, by examination with a magnifying glaſs, a veſſel may be ſeen to ramify upon it.

Upon opening the yolk-bag, and waſhing off the yolk, the ſpongy coat is ſeen to be elevated in the courſe of the blood-veſſels of the vaſcular area: this is the firſt appearance of the valvular ſtructure of the yolk-bag, of which more hereafter.

The *fœtus* is ſtill more curved in its form, the prominence correſponding to the bill being bent down upon the breaſt. The rudiments of the upper extremities are apparent: they are two white buds or ſhort projections. The lower limbs are likewiſe produced, but without any more form. The cerebral veſicles are more eminent; and, when opened, their contents are found, though ſtill pellucid, to be mixed with ſome whitiſh fibres, which form opaque clouds, and are the commencement of the brain.

Haller found the *heart* beginning to undergo ſome changes about this period. The *auricle*, when viewed in the uſual manner on the right ſide of the fœtus, is ſeen to contain two ſemicircles. The moſt poſterior of theſe, or the one neareſt the vertebræ, is the largeſt, and terminates the auricle. The anterior ſemicircle is ſmaller, and divides the auricle as a kind of ſeptum. This is the firſt appearance of the diſtinction of the auricles into two. That which is to be called the left is the larger, and projects over the right poſteriorly. The latter, which is the ſmaller, has a ſemilunar termination, which is compriſed in the breadth of the left auricle. The vena cava and the auricular canal are inſerted in the interval of the two auricles.

The diſtinction of two auricles is likewiſe to be ſeen on viewing the heart on the left ſide. That which is to become the left is oval, wider than the other, and paſſes beyond the auricular canal.

At the end of the fourth day, or ſoon afterwards, the two auricles become more ſeparate from the vena cava and the auricular canal. They project over theſe veſſels, and are elevated from the two ſides of the baſe of the heart into a pointed top. The whole of the auricle, or the united reſervoir of the right and left auricles, appears then as a ſac with two pointed horns: each of theſe pointed tops has a ſeparate drop of blood. The border of both the auricles appears at this time notched. Mem. 2d ſur la Formation du Cœur dans le Poulet, &c. par M. de Haller, p. 70.

The *auricular canal*, towards the end of the fourth day, paſſes more in a direction from above downwards than formerly.

According to Maitre Jan, the rudiments of the *lungs* are viſible at this period; but Haller aſſerts that they do not appear before the 138th hour. The former author deſcribes at this time, in the neighbourhood of the heart, little reddiſh clouds, apparently of a ſpongy nature, which appear more or leſs red, alternately, as the heart moves, and which remain of an uniform colour when the heart has ceaſed to beat. Maitre Jan admits that the pulmonary veſſels cannot yet be diſcerned, but ſuppoſes from the above effect of the heart's motion, that they do exiſt, although they are not viſible. (Obſervat. ſur la Formation du Poulet, par Maitre Jan, p. 115 and 122.)—Not having examined this point, we cannot decide between theſe authorities, but we ſhould judge it improbable that the pulmonary veſſels could regularly tranſmit blood to the lungs, and yet not be viſible.

Both Haller and Maitre Jan agree that the *liver* makes its appearance towards the end of the fourth day. It is ſeen as a viſcous cloud of a reddiſh yellow colour, ſituated between the umbilical veſſels and the deſcending aorta. It is rendered more viſible and opaque by moiſtening it with diſtilled vinegar.

The *eye* of the fœtus appears black, the choroid coat being formed; and the ſuperior part of the eye chiefly preſenting itſelf to view, the pupil is ſituated in the inferior portion of the eye.

The end of the fifth day, or 120 *hours*, the *vaſcular area* is ſo much extended as to cover generally more than half the ſuperficies of the yolk-bag. The trunks of the veſſels are proportionally increaſed in ſize, but the branches near the circumference are not ſo much advanced. Some additional veſſels are ſeen to proceed from the umbilicus of the chick towards the left ſide of the area. Theſe appertain to the veſicula umbilicalis, as will be better underſtood hereafter. All the blood-veſſels of the area, which were in the firſt days of incubation of a fine ſcarlet, are now commonly found of a duſky red colour.

The *amnios* continues to increaſe in magnitude, and contains ſo much fluid, that the chick appears to be ſurrounded by a green liquor.

The *chick*, eſpecially when excited by a little external heat, can be perceived to move its limbs.

When the external membrane is removed, the *veſicula umbilicalis* is found to be conſiderably larger than it was the preceding day. It is likewiſe perceived to have contracted ſome adheſion with the external membrane, which however is undone by a ſlight force, particularly after the membranes have been a ſhort time immerſed in vinegar or ſpirits.

The branches of blood-veſſels which are diſtributed upon the veſicula, belong to a trunk that comes out through the opening of the abdomen at the umbilicus of the chick. The veſicula is connected with the fœtus by means of a neck, or contracted part, which is likewiſe received into the abdomen at the umbilicus.

Maitre Jan deſcribesat this period a number of fine branches of blood-veſſels upon the ſkin of the chick: we have not, however, obſerved theſe ſo early.

When the internal ſurface of the *yolk-bag* is examined, it is found that the eminences upon it, already mentioned, have aſſumed the form of veſſels ramifying from the centre, where the chick is ſituated, to the circumference of the vaſcular area. This appearance has been miſtaken by many of the older anatomiſts for real veſſels diſtributed upon the inner ſurface of the yolk-bag, and were ſuppoſed by ſome to be deſigned to convey the yolk to the chick. When the appearance of the yellow veſſels of the yolk-bag is firſt preſented, it is very difficult to detect the real occaſion of it, but as it advances, it becomes plain that the effect is produced by the inflection or doubling of the inner membrane of the yolk-bag, in the courſe of the real blood-veſſels of the bag. By a careful examination of the matter with a lens, even at this period, we have always perceived the appearance of yellow veſſels to ariſe from the blood-veſſels running in grooves, or reflections of the inner membrane. When the two tunics of the bag are ſeparated, the blood-veſſels are found to belong to the external, upon the inner ſide of which they appear as eminent lines; while upon the external ſide of the inner coat there are correſponding grooves or impreſſions.

The *heart* at this period begins to undergo the changes by which it approximates in ſtructure the heart of the adult bird. It becomes perpendicular, or in the line of the fœtus, from being placed in a tranſverſe direction. The point is recurved between the two lobes of the liver.

The *auricles* become more diſtinct, and the interval between them white.

The *auricular* canal is conſiderably ſhortened.

The *ſecond* or *right ventricle* begins to be formed before the termination of the fifth day. It appears as a little ſac under the bulb of the aorta. It is much ſhorter than the original ventricle, above which it is placed. Its figure is oval, and it has a red colour. In a ſhort time the new ventricle is ſeen in its proper ſituation, that is, on the right ſide of the heart. Haller ſtates that he found it placed on the right as early as the 117th hour. There are then two diſtinct drops of blood in this part of the heart of the fœtus, and a white line is perceived between them.

The *aorta* ariſes from the left ventricle. The branches, which are furniſhed in order to form the dorſal aorta, have an inclination downwards, and unite in an acute angle. At this period alſo the bulb of the aorta begins to diminiſh, and to retire into the fleſh of the heart.

The *liver* is more diſtinct than at the end of the preceding day; it is divided into lobes, and is of a pale or yellowiſh red colour. Its veſſels receive blood.

Haller firſt perceived the rectum at this period, although the ſtomach and other inteſtines were not yet formed. It appears in the ſhape of a trident, the lateral proceſſes of which are produced by the rudiments of the two cœca.

The End of the 6th Day, or 144 *Hours.*—Eggs placed ſo long under the hen are conſiderably diminiſhed in weight, which is even perceivable on taking them into the hand. The ſhell begins to appear more dry, and opaque coloured, and is more fragile than before incubation.

The diminution of weight depends upon the enlargement of the air-cell, which now extends over a conſiderable part of the great end of the egg. Maitre Jan has taken ſome pains to prove that the air contained in the egg is not derived from the atmoſphere. He ſuppoſed that the fluids filtered through the inner layer of the membrane which lines the ſhell, and that by the action of heat, they were volatilized or converted into air. This opinion is not only improbable, but refuted by particular facts. On opening the air-cell, we do not find its ſurface to poſſeſs any moiſture; that layer of the membrane which lies next the humours of the egg, although leſs thick, is ſmoother, denſer, and leſs porous than the layer immediately in contact with the ſhell, and therefore leſs fitted to admit the tranſpiration of either fluids or air. The chemical properties of the gaſeous contents of the air-cell ſeem to put it beyond all doubt that the atmoſpheric air paſſes into the egg. (See the article Egg.) We ſhall only add, that when we have varniſhed the external ſurface of the ſhell the air-cell no longer increaſed in ſize.

Upon opening an egg at this period of incubation, it is not unuſual to ſee the chick turned upon its back, inſtead of lying, as before, upon its left ſide. This circumſtance ſeems to depend upon the amnios having ſo much increaſed in ſize that the fœtus may roll round within it.

The membranes around the chick begin to acquire more ſtrength and firmneſs, which is the conſequence of the veſicula umbilicalis becoming more cloſely and extenſively united to the external membrane.

The *veſicula* is now found to be very much increaſed in magnitude, and to cover a conſiderable portion of the yolk-bag. When the membranes ſurrounding it are cut open, and the veſicle expoſed, its neck or peduncle may be traced as a fine tranſparent tube to the rectum, by a careful examination, particularly if the parts have been rendered opaque, by being a ſhort time ſteeped in vinegar or ſtrong ſpirits. Where it opens into the rectum it is dilated.

The connection that exiſts between the veſicula umbilicalis, and the end of the rectum, by means of a tube analogous to the urachus, has induced Haller and others to conſider this bag as the reſervoir of urine.

We ſhall find in the ſubſequent periods of incubation, that the veſicula umbilicalis performs very important and other functions than thoſe of a reſervoir of urine, in which, nevertheleſs, it does not perhaps materially differ from the allantois of quadrupeds.

It is neceſſary here to notice an error which two of the beſt writers upon the ſubject of incubation have fallen into with reſpect to the veſicula umbilicalis. Both Malpighi and Maitre Jan ſuppoſed it to be a part which afterwards became the ſtomach of the chick. This miſtake appears to have been occaſioned by the veſicula becoming, as we ſhall afterwards deſcribe, ſo much extended as to loſe the figure of a bag, and from being united to other membranes, only to be diſtinguiſhed with difficulty. Its being viſible nearly three days before the ſtomach; acquiring even then a much greater ſize than that viſcus poſſeſſes, and differing eſſentially in figure and texture, ſhould however have prevented theſe two parts from being confounded with each other.

The *chick*, on the ſixth day, has aſſumed a good deal of its natural form. The extremities are ſo much developed, that the diviſions of theſe members are viſible. The wings have their bent figure, and the legs are added to the thighs.

This period is likewiſe marked by the firſt appearance of moſt of the important organs of the body, beſides ſome changes in thoſe already formed.

Haller ſtates that he could diſcern the *pericardium* at this time.

The two *auricles* are ſtill more diſtinct than at the end of the preceding day.

The *auricular canal*, which had before begun to retire within the fleſh of the heart, is now not viſible.

The *ventricles* are better formed, and broad at their baſe.

The *bulb*, the *ſtrait*, and the *beak* of the aorta, which gave origin, in the early periods, to the principal arterial trunk, are in general not apparent at the end of the ſixth day. This veſſel is ſeen to come forth from the baſis of the heart itſelf.

The *pulmonary* artery was ſeen by Haller firſt, about the middle of the ſixth day. This veſſel is leſs firm and opaque than the aorta; it ariſes from the left ſide of the baſis of the heart with a little bulb. It is uſually of leſs diameter than the aorta. Almoſt at its exit from the heart it divides into two branches.

The branch on the left ſide forms an arch, in order to reach the lung of that ſide in paſſing behind the bronchia: it joins the aorta, towards the third vertebra of the back. The branch of the pulmonary artery, which is inſerted into the dorſal aorta, is longer than the *ductus arterioſus* of quadrupeds, to which it is analogous. It ſhould, however, receive the name of *left*, as birds have a ſimilar arterial duct upon the right ſide. The left lung receives a conſiderable branch from the ductus while on its way to join the aorta.

The other principal branch of the pulmonary artery paſſes tranſverſely to the right ſide, under the aorta; to which it adheres. It furniſhes the artery to the right lung, and deſcends behind the bronchia, in order to open into the aorta, higher than the left branch already mentioned. The right arterial duct is much ſmaller than the left.

Theſe arterial ducts are two of the three branches, which have been deſcribed in the preceding days as contributing to form the dorſal aorta. The right duct is later in appearing than the other, and hence, when the aorta is firſt diſcovered, it is obſerved to be only formed by two branches.

About this period the *lungs* have ſufficient conſiſtence to be viſible. When they are rendered opaque by vinegar, they are found to be not ſo ſmall, that they might not have been ſeen ſome time before if their tranſparency had permitted it. Their figure is cylindric. They are attached poſteriorly to the back, and connected with the two ſides of the heart.

The *liver* has acquired more of its future form than it had the preceding day.

The *ſtomach* is apparent at this time. It is very thin and tender, and reſembles a good deal the form of the human ſtomach; its orifices are, however, nearer to each other. The ſtomach is received between the lobes of the liver.

The fluid contained in the *cerebral veſicles* has acquired by this time ſome conſiſtence.

The *kidnies* are diſcovered during this day as long reddiſh granulated lines or traces in the loins.

The End of the 7th Day, or 168 *Hours*.—Upon opening an egg at this period, we perceive that the changes already mentioned in the form, conſiſtence, and ſituation of the humours have continued to increaſe.

The *white* tends more towards the lower part and ſmall end of the egg: it continues to diminiſh, and to become more tenacious in its compoſition.

The *yolk* is more fluid, more ſpread out, and apparently of a larger ſize than before. Haller nevertheleſs found it at this date to poſſeſs its original weight.

The *blood-veſſels* which are diſtributed upon the membranes, and which were in the firſt days, as before mentioned, of a brilliant ſcarlet, are now in moſt eggs found to be all of the purple or venous colour. The uniformity of colour makes it difficult to diſtinguiſh the arteries: they can indeed be only aſcertained by diſſecting the membranes and purſuing the courſe of the veſſels into the body of the chick.

The *amnios* is ſtill larger at this than any previous period; it preſerves its kidney form, and its fluid is tranſparent, and cannot be rendered opaque, or coagulated by vinegar or ſpirits.

The *veſicula umbilicalis* goes on increaſing in ſize, and its veſſels acquire ſtrength.

The *chick* has its members more developed. The *feet* are added to the poſterior extremities, and even the *toes* can be diſcerned. Oſſification has commenced. Haller ſtates that he prepared the *femur* and *tibia* at the 146th hour. The *two mandibles* begin to form at the under part of the head, leaving an aperture between them, which is to be the mouth.

Haller at this period obſerved the firſt convolutions of the *ſmall inteſtines*, which were ſo extremely tender as not to admit of being touched, although the rectum was apparent two days before.

The *ſpleen* now firſt makes its appearance. Haller ſuppoſed that he could likewiſe diſcern the *renal capſules* and *ovaries*.

The intermediate of the three veſſels which ariſe from the heart to form the dorſal aorta, is, about this time, ſeen to furniſh the *two carotids*; it is the ſame veſſel which becomes the *deſcending aorta*, when the ſtructure of the pulmonary artery is completed. Haller ſtates that the pulſation of the aorta ceaſes after the 154th hour.

The *eye* of the fœtus is conſiderably developed at the preſent period. The three humours exiſt: the *vitreous* is extremely abundant, upon which depends the great bulk of the eyes of the chick about this time. The *lens* is ſmall. The *iris* is formed, but is very tranſparent. The trunks of the *optic nerves* and *retina* are viſible. The latter is tranſparent and plaited, and ſeems to go as far as the lens. The radiated black lines which form the *corona ciliaris* are ſeen through the retina, placed around the external part of the lens.

The End of the 8th Day, or 192 Hours.—The *vaſcular area* has increaſed ſo much by this time, that it very nearly covers all the ſuperficies of the yolk-bag, except what is in contact with the white. The branches of veſſels, however, begin to decline or diſappear in ſome parts, particularly towards the circumference, although the trunks are larger than at any former period.

The blood-veſſels belonging to the veſicula umbilicalis are conſiderably enlarged and extended, and are now ſeen to turn backwards, or be reflected upon themſelves in the direction of the chick. The reflected portion of the veſſels of the veſicula appears to be diſtributed to the ſuperior half of that bag which is now in contact with the external membrane. This membrane, which was in the firſt periods of incubation, as already mentioned, perfectly tranſparent, by its connection with the veſicula becomes vaſcular, and acquires ſtrength, and contributes to form a complete ſac, which envelopes in the latter days all the humours and the chick, as will be hereafter deſcribed.

The veſicula umbilicalis is found at the preſent period to have a conſiderable extent, according to our obſervations much greater than has been repreſented by anatomiſts in general, who do not ſeem to have been acquainted with the uſes of this bag in the later ſtages of incubation.

The *chick* is a very pale pink colour, or white ſlightly tinged with red, in conſequence of the vaſcularity of the ſurface preparatory to the formation of the ſkin and feathers.

When the *head* of the *chick* is viewed poſteriorly, it preſents the appearances of four eminences, which are an opaque white, and are joined to each other by tranſparent membranes. Maitre Jan conſiders them as the rudiments of the bones of the cranium in a cartilaginous ſtate, and the tranſparent parts as correſponding to the ſutures and fontanel. Haller ſpeaks of theſe eminences as four lobes of the brain. We conceive the account of Maitre Jan to be more correct.

The head being opened at this period by Maitre Jan, he ſtates that he diſtinguiſhed the *membranes*, the *ſinuſes*, and the *veſſels* of the brain, and that the ſubſtance of the *cerebrum* and *cerebellum* was well formed, the *convolutions* even being apparent. This obſervation, according to our experience, is premature.

The ſtructure of the *eye* is more perfect than before. The *ciliary zone*, according to Haller, is as perfect at the preſent period as at any time afterwards. Its deſcription, however, is eaſier ſome days later.

The *bill* of the chick is cartilaginous. The animal occaſionally opens it in the water of the amnios as if attempting to ſwallow.

The breaſt of the fœtus, which was covered by a thin membrane, that in the firſt days was ſo tranſparent, as to give riſe to the miſtake of the heart being outſide the cheſt, has at the preſent time ſome fleſh upon it. About this period alſo the rudiments of the *ſternum* and of the *ribs* may be diſcovered.

The *gall-bladder* makes its firſt appearance towards the end of the eighth day, at which period, and for a few days afterwards, it is very ſmall and without colour.

About this time the reflections of the inner tunic of the yolk-bag, which we have deſcribed at the end of the fifth day, as putting on the appearance of yellow veſſels, acquire more decidedly the form of valves. They ſtill preſerve the ſame ſituation and courſe, commencing under the bed of the fœtus, and extending outwards in a radiated manner towards the circumference of the vaſcular area, where they terminate. They are made of a number of plaits or folds which have a tranſverſe direction, and which are more prominent, or have deeper folds in proportion as the valvular lines approach the circumference of the circle. They form merely waves where they commence, and at the preſent period they are on every part of the yolk-bag much leſs marked and ſtriking than they become towards the end of incubation.

The End of the 9th Day, or 216 Hours.—Maitre Jan mentions the appearance of ſome new parts at this period which we have not met with ſo early. He deſcribes the *kidnies* as ſecreting a milky fluid, which he ſaw diſtending the *ureters*. He diſcovered about this time the *crop* and the *trachea* and was not only able to diſtinguiſh the principal diviſions of the *brain*, but ſtates that he could diſcern the *ventricles* with the *eminences* they contained, and even the *plexus choroides*. He likewiſe ſaw upon the baſis of the brain the greater number of the *nerves* that ariſe there, more particularly the *optic* and *auditory* nerves, and found the *ſpinal marrow* to be ſplit or compoſed of two parts at its origin. He diſſected the nerves of the ſpinal marrow, which, although very ſmall, he ſtates to be much more firm than thoſe which take their origin from the brain. Obſerv. ſur la Formation de Poulet, p. 189.

The ſurface of the fœtus exhibits now a number of pores; theſe are principally ſituated upon the thighs, the back, the neck, and the wings, and are the apertures of the cells in which the *feathers* are formed.

The *eyes* are larger than the veſicles of the brain; their form is not ſpherical, but flattened upon the anterior and poſterior ſides.

The *iris* is ſtill thin and tranſparent; but there are ſeen through it and the tranſparent cornea five or ſix white points which form a circle. When the eye is opened carefully with a lancet, theſe points are found to be elongated, and to form little lines, or ciliary fibres, which at this period are white.

Maitre Jan ſtates the *eyelids* to be formed at this time, but to be ſo tranſparent as to be inviſible, unleſs after preparation by a ſtrong acid.

The *inteſtines* are now ſo firm, that they can be examined without danger of breaking them.

The *yolk-bag*, according to Maitre Jan, begins to form two lobes, a larger and a ſmaller; but we have not obſerved this change to take place before the 11th or 12th day.

Maitre Jan made the experiment of boiling an egg at this period, after having fixed it upon a plate of lead with its ſmall end downwards. When deſpoiled of the ſhell, and the chick removed, the depreſſion in which the amnios lay was fully expoſed, and found to be very conſiderable. He then made a ſection of the egg in the vertical direction, dividing the depreſſion of the yolk through the middle, when there appeared a round ſpace about the eighth of an inch in diameter, filled with a whitiſh curdy matter, and another ſpace around this of a larger extent, containing a firmer matter than the firſt, and of a paler yellow than the reſt of the yolk. Maitre Jan, very erroneouſly in our opinion, ſuppoſed the white curdy ſubſtance to be the inteſtines of the fœtal chick. Theſe do not project from the abdomen in ſufficient quantity to account for the appearance, admitting that they had been ſeparated from the chick, and had adhered to the yolk during the boiling of the egg. This appearance, we believe, ariſes from the ſame change of organization in the yolk being continued, which in the early periods of incubation produced the whitiſh appearance under and around the bed of the chick. The firm, pale yellow texture of the yolk which encompaſſes that juſt mentioned, Maitre Jan accounts for by ſuppoſing that the fluid parts of the yolk in the neighbourhood of the chick had paſſed into the amnios. There can be no doubt that different parts of the ſubſtance of the yolk are differently conſtituted, which difference is preſerved notwithſtanding the motions that eggs may experience; a fact that cannot perhaps be fully explained, but which proves that animal fluids have their peculiar organization, which they can maintain as well as the ſolids. When the fluids change this compoſition, it is often by ſome vital action in themſelves, inſtead of a fermentative proceſs, or the mechanical operation of the ſolids upon them, as is commonly ſuppoſed.

In making the experiment of boiling eggs at this period, Maitre Jan did not find that the amnios was coagulated, although Haller ſtated that the liquid of the amnios is coagulable at the 198th hour.

The *valvular ſtructure* upon the internal ſurface of the *yolk-bag* is more prominent, and when minutely examined, it is found to receive branches of the blood-veſſels which are given off at right angles with the plane of the ſurface of the bag, and having penetrated towards the edge of each valve, there unite and form a ſingle veſſel, which runs within that edge. This ſtructure is better ſeen a few days afterwards.

The End of the 10*th Day, or* 240 *Hours.*—The *veſicula umbilicalis* has now a very conſiderable extent, occupying the greateſt part of the ſurface of the vaſcular area, which laſt is ſpread over almoſt the whole of the yolk-bag. The portion of the bag that is applied to the white, is not at this date the ¼th of the whole. The chalazœ, therefore, are much nearer to each other than when we laſt mentioned them. The white is confined almoſt entirely to the lower part of the egg, and its maſs continues daily to diminiſh, while, on the contrary, the bulk and quantity of the yolk appears to be increaſed.

The *external membrane* is firm and fleſhy where it is ſtrengthened by the veſicula umbilicalis. Some of its veſſels are ſeen to extend to the white, upon which a fine pellicle may be obſerved to grow, and which is the firſt appearance of a membrane to this humour, notwithſtanding ſome authors ſpeak of the *membrana albuminis* as an original ſtructure, and others, amongſt whom is Blumenbach, deſcribe the membrane which lines the ſhell as belonging to the white.

The *amnios* is larger, its membrane more firm, and the fluid leſs clear and limpid than before. It has contracted ſome adheſions with the veſicula umbilicalis, and by that means, with the external membrane. Theſe adheſions are particularly in the courſe of the blood-veſſels, that are diſtributed to the veſicula and external membrane. One of theſe veſſels is always ſeen to paſs acroſs the back of the chick, at which place it is involved in a reflection of very fine membrane, which is connected with that of the amnios.

The *chick* is very much curved at this period: its beak is uſually doubled down between its feet. The *feathers* are apparent.

The external form of the *head* bears a greater reſemblance to that of the full-grown bird, except that the eyes are ſtill enormouſly large.

The *eyelids* are evidently formed, and are occaſionally moved by the chick. The *membrana nictitans* is likewiſe to be ſeen.

Haller prepared at this period the *ciliary zone* and radiated appearance called the *crown*, with the membrane on which the latter is ſuſtained, although he ſtates that theſe parts are formed on the 8th day, or before it.

He ſays he has ſeen on the 7th day the corona ciliaris, or corpus ciliare of Morgagni. At this epoch the retina, which is in thick folds, appears to go as far forwards as the cryſtalline lens, behind the corona ciliaris, with which it is covered, and which is dimly ſeen acroſs it. He believes, notwithſtanding, that the retina does not proceed to the lens; that the appearance of its doing ſo ariſes from its thickneſs and folds leaving ſo ſmall a ſpace between it and the lens, and that the membrane which ſupports the ciliary zone and crown, and is attached to the cryſtalline, is different from the retina.

The corona ciliaris is a row of black lines arranged alternately, long and ſhort, in ſome degree parallel, but converging as rays proceeding from the external circumference of the uvea to the cryſtalline lens. The ciliary crown is not formed entirely in the ſame manner in quadrupeds and birds. In the former it appears, when examined by a microſcope, to be compoſed of a plicated membrane, upon which ſome ramified veſſels advance towards the cryſtalline. In birds there are only ſome ſerpentine lines folded upon themſelves, which are very numerous in the contour of the ciliary crown, and of which many unite to form ſingle ones: they are joined together by theſe branches, and are covered with a black pigment.

The figure of the ciliary zone and crown is not a perfect circle, but it is broader on one ſide than the other.

The greater number of anatomiſts have deſcribed the corona ciliaris as reſting immediately upon the membrane of the vitreous humour. Others have believed that the retina extends to the cryſtalline, and that the corona is ſupported upon it. Since Zinn's publication upon the anatomy of the eye, the ſtructure of the ciliary body in man and quadrupeds has been well underſtood; but in birds the lamina, which ſerves for the baſe of the corona ciliaris, does not come from the membrane of the vitreous humour.

The membrane, which is placed under the corona ciliaris in birds, is to be ſeen from the 8th day. It is radiated, opaque, and a little aſh-coloured; more thin than the retina, and thicker than the membrane of the vitreous humour. It is of the ſame dimenſions as the corona ciliaris, and in a degree attached to the corona, and much more firmly united in the latter days of incubation; and after the excluſion of the chick, it adheres by its poſterior extremity to the great circle of the retina, and by the other to the cryſtalline lens.

The retina terminates by a diſtinctly formed circle, which is a little ſtrengthened at the circumference of the corona ciliaris, and at that of the zone. The plane of the retina is continued with that of the corona; the zone is placed more poſteriorly than the retina. Its external part, which reſts upon the vitreous humour, is nearly horizontal, and its internal part becomes ſtraight again in order to be attached to the cryſtalline lens. It does not adhere to the membrane of the vitreous humour when the chick is but little advanced. It remains often placed upon that membrane without being attached to it, and when the chick is more formed, or after incubation is finiſhed, it quits the membrane of the vitreous humour, in order to remain connected to the corona ciliaris, with which it becomes inſeparably united in the end.

The circumference of the ciliary zone, in the latter days of incubation, can be ſeparated from the membrane of the vitreous humour without leaving any ſhreds. It is diſtinguiſhed from the retina by its fineneſs and being ſeparable from the latter without being torn; but it is continued with the poſterior and inferior part of that membrane. It differs ſtill more from the membrane of the vitreous humour; it is thicker, it has more brown and leſs blue in its colour. Acids, when applied to it, affect its colour more than they do that of the vitreous membrane. It is ſituated anteriorly upon that membrane, in another plane, and evidently ſuſtained by it, and conſequently ought not to be confounded with it.

The canal of Petit does not exiſt. The membrane of the vitreous humour proceeds, without ſtopping behind the ciliary zone to be attached to the cryſtalline lens, that it ſuſtains, and which remains in its place even when the corona ciliaris has been raiſed.

The ciliary zone is eaſy to prepare even in the chick but little advanced. One method is to cut off the cornea and iris; and having waſhed away the black pigment with which the corona ciliaris is covered, it will appear between the intervals of the ciliary rays; and if ſome of thoſe rays be elevated, it will be ſeen in its proper place. It is practicable to make the lens come forth from its depreſſion, and to elevate it with the corona ciliaris, with which it is connected; and ſometimes it may be poſſible to leave the zone reſting upon the membrane of the vitreous humour.

An eaſier mode of preparation is to cut the ſclerotic coat through the middle, and to plunge the anterior half of the eye into vinegar. After ſome hours immerſion in that fluid, if the back of a fine ſcalpel be inſinuated between the retina and the choroid coat, and the vitreous and cryſtalline humours be removed, one ſometimes ſucceeds in obtaining the ciliary zone alone, the corona remaining attached to the choroid. It is rare to have the zone entire, but a conſiderable part of it is commonly preſerved, and particularly the whole of the external circle. When the experiment fails, it is the interior circle which remains attached to the corona.

In the above account of the ciliary zone and crown, we have anticipated many facts that are obſervable during the laſt days of incubation, and even after that proceſs terminates, in order to render the hiſtory of thoſe parts more intelligible. We have alſo been induced to borrow the preceding deſcription from Haller, who made the ſtructure of the ciliary zone and crown in the chick a particular ſubject of inveſtigation, as we have not much attended to the progreſs of the eye during incubation. See Mem. ſur la Format. du Cœur dans le Poulet, ſur l'Œil, &c. Obſerv. 180, 181, 182, 191, 192, 193, 215, 216, 226, 228, 231, 239, 240, 247, 249, 253, 254, 256, 261, 262, &c. and ſect. xii. Mem. ſecond par M. Haller. The *ſmall tubercle*, from whence the aorta and pulmonary arteries ariſe, and which appears to have been a remnant of the bulb of the aorta, entirely diſappears about the preſent period.

The *right ventricle* of the heart is ſtill about the one-fourth of its length ſhorter than the left.

Thoſe *bones* of the chick, according to Haller's obſervations, which are now formed, are merely in a cartilaginous ſtate; even the *cranium*, which was apparent ſome time before the preſent.

The *umbilical opening*, through which the urachus and the blood-veſſels communicate with the interior of the body of the chick, forms a projection, or a ſort of tube, which in a few days becomes more ſtriking. Some of the convolutions of the inteſtines may be ſeen in this opening, but the greateſt part of the inteſtines is contained in the body of the fœtus.

The end of the 11*th day, or* 264 *hours*, the *external membrane* goes on ſtrengthening, by its connection with the *veſicula umbilicalis*. This laſt is now ſo extenſively united to the external membrane and the amnios, that it is only by great care, and after being macerated in ſpirits, that it can be liberated from its connections, and expoſed as a diſtinct bag, pendent from the umbilicus. When thus ſeparated by diſſection, it is ſeen to be a large ſac, compoſed of a thick fleſhy membrane and hardly containing any fluid. The ſtrength of the bag appears to depend upon a reflection of ſome of the other membranes covering and being inſeparably adherent to it, for at the umbilicus the veſicula is thin. Haller traced the urachus from the veſicula to the rectum after the preſent period, and even until the laſt day of incubation; but in our obſervations it has appeared that the connection of the veſicula with the chick, except by means of the blood-veſſels, after this time, is very obſcure.

The whole of the body of the chick is now ſeen to be covered with *feathers*.

Haller at this period firſt diſcovered the *tongue*.

The ſubſtance of the *brain* is ſtill found to be a very ſoft pulp.

The *liver*, in moſt inſtances, has a yellow colour, but in ſome the red predominates.

Bile is evidently ſecreted: the *gall-bag* is green, and a greeniſh or yellow fluid is commonly found in the ſtomach. The inteſtines likewiſe appear to contain bile, or at leaſt a bitter fluid.

The *renal capſules* are evident; they have, according to Haller, the form of an S.

The tube or ſheath which projects at the umbilicus is better formed.

The *blood-veſſels*, which come out at this place, are eaſily traced from different ſources. Thoſe which are diſtributed to the external membrane and veſicula come from the loins, and thoſe belonging to the yolk-bag are from the abdomen.

The end of the 12*th day, or* 288 *hours*, the *chick* has more of the figure of the adult bird than at any preceding period. The extremities are larger, and the head ſmaller, in proportion to the reſt of the body. The bill is more pointed, and of a harder ſubſtance.

The *ſtomach* has gained greater ſtrength; it contains a white coagulated or curd-like ſubſtance.

There is *bile* found in all the inteſtines, which is very bitter.

On the outſide of the umbilical ſheath there are ſome folds of the inteſtines, with one of which the yolk-bag is ſeen to be connected by a ſhort proceſs, which is evidently the continuation of the alimentary canal into the yolk-bag. This part has commonly, and as we ſhall hereafter ſee very deſervedly, received the name of *ductus vitello-inteſtinalis*. Although we have not obſerved the duct before the preſent date, there is every reaſon to ſuppoſe that it is coeval with the inteſtines.

Malpighi ſtates that he ſaw the *ſtomach* of the chick on the outſide of the umbilical ſheath: but this would ſeem to be an error. The ſtomach, it is true, is ſituated low down in the belly, but, as far as our obſervation goes, it never is protruded from that cavity.

The ſtructure of the *eye* is the ſame that is deſcribed on the 11th day. It is proper to remark, that at no period is there to be found in the chick a *membrana pupillaris*.

The *yolk-bag*, according to our obſervations, begins in general to alter its figure. Before this date it was an irregularly round maſs, containing two depreſſions; one for accommodating the chick and amnios at the upper ſide, and another at the lower part of the yolk, in which the white is partially lodged. The latter is a regular depreſſion, and before this period contracts in breadth, although it becomes ſomewhat greater in depth; an alteration which ariſes from the diminution of the white, and from the chalazæ tending to approach each other, and thereby to bring the two poles of the yolk, at which theſe bodies were originally attached, together on the lower ſurface of the yolk. The approximation of the chalazæ ſeems likewiſe to occaſion, in the firſt inſtance, the diviſion of the yolk-bag into lobes. At the preſent period the bag forms two lobes, one large and one ſmall. Theſe afterwards, by the compreſſion of the chick, are uſually moulded into three, but in the egg of ſome other birds into a greater number: thus the yolk-bag in the *Guinea fowl* is divided into ſix or ſeven lobes.

The End of the 13th Day, or 312 Hours.—Upon opening an egg at this period, and removing the contents from the ſhell, the *white* is found to have aſſumed a greeniſh hue, and to have more conſiſtence than at any of the former periods; and it is incloſed entirely by a fine film, which retains it in one poſition, and in ſtrict connection with the depreſſion on the inferior ſurface of the yolk-bag. The external veſſels are diſtributed over the whole white.

The *yolk-bag* has ſtill more of the lobulated figure, and the chick lies obliquely acroſs the bag in the ſuperior depreſſion between the two lobes.

The *valvular* ſtructure on the internal ſurface of the yolk-bag, which we have noticed before, has now arrived at perfection. The valves are more eminent, form numerous folds or coils, their edges appear to be covered by tubes which are convoluted upon themſelves in the manner of inteſtines. Theſe have been called by Haller the *vermiform* and *inteſtiniform tubes*, and have been deſcribed both by him and other anatomiſts as real veſſels: but they have always appeared, in our examinations, as reflections or proceſſes of the valvular ſtructure, in the ſubſtance of which the real blood-veſſels ramify. Maitre Jan ſpeaks of them as veſſels which collect the fluid of the yolk, and which afterwards terminate in the blood-veſſels. Haller conſiders the blood-veſſels which run in the edge of the valves as a diſtinct order of veſſels, that end in the trunks of the veins of the yolk-bag, and which take their origin at the circle, that exiſts in the latter days of incubation around the line where the yolk and white are joined to each other. We have already ſaid that the veſſels upon the edges of the valves have numerous communications with thoſe that run along the roots or baſes of the valves, and which belong to the external tunic of the yolk-bag, and were originally the ſame veſſels that formed the vaſcular area. The venous circle of the yolk-bag, we have no doubt, is the ſame that in the early ſtages of incubation has been deſcribed as the contour of the vaſcular area: and the vermiform tubes appear to be the villous or ſpongy proceſſes of the external ſurface of the yolk-bag, which appeared in the firſt days greatly extended, and grown into the form now deſcribed.

The *chick*, at the preſent period, has ſtill more of its perfect form; its head is much curved, and the bill is placed under the wing, which poſition is preſerved throughout incubation.

The *bill* is pointed and has its natural figure. Haller ſtates, that the chick is often perceived to open and ſhut the bill about this period and afterwards. Maitre Jan, on the contrary, although the chick moves its limbs frequently and ſtrongly, aſſerts, that it does not open its mouth. We have not attended to this circumſtance, from conſidering it of little conſequence, and no way explaining the mode in which the chick is nouriſhed.

The *internal organs* of the *chick* are conſiderably advanced towards perfection. The *brain*, although ſtill ſoft and pulpy, is well formed. The *kidnies* and *teſtes* are completed in their figure. The *ſpleen* reſembles a conglobate gland. The *lungs* are of greater ſize than the heart.

The firſt branch that the aorta gives after its exit from the heart is the *left carotid*, which gives off the *ſubclavian artery* of that ſide. The trunk of the aorta then forms an arch, which turns to the right. It ſends off the *right carotid*, and approaches the vertebræ in paſſing behind the right lung: it is united to the ductus arterioſus above the liver.

The right ventricle of the heart is ſtill ſhorter than the left; it is of an oval figure, but the latter ends in a point.

The end of the 14th day, or 336 hours, the changes in the humours and the formation of the organs of the chick are found to have made progreſs ſince the preceding day.

We have already ſtated that the membrane which is external to the chick and the yolk-bag, and which is ſcarcely palpable in the firſt days of incubation, gains ſtrength and receives veſſels after the veſicula umbilicalis has acquired ſome ſize, and has adhered to it. The magnitude of the veſſels, and the thickneſs of this membrane, increaſe in proportion as the veſicula umbilicalis grows: we therefore conceive that the developement of this membrane depends upon its connection with the veſicula and the blood-veſſels which it derives from that bag. We have obſerved, that ſome days before the preſent period, the external membrane begins to extend over the white, which it uſually encloſes about the 14th day: it therefore forms a perfect ſac, containing the chick in its amnios, the yolk-bag, and the white.

The veſicula umbilicalis about this period has arrived at a very great ſize; its extent cannot be eaſily aſcertained, as it is ſo much incorporated with the external membrane, that they cannot be ſeparated or accurately diſtinguiſhed: but we ſhould conceive that the veſicula exceeds in ſize the yolk-bag, as there is the appearance of the external membrane being thickened and ſtrengthened by one under it as far as the yolk extends.

The manner in which the veſicula concurs to form a membrane which inveſts all the contents of the egg, appears to be ſimilar to the reflection of the ſerous membranes of the thorax and abdomen, in order to cover the viſcera and line the parietes of theſe cavities. It ſhould however be obſerved, that when it is opened, there is no appearance of its forming an immediate tunic ſimilar to the pleura pulmonalis, but it ſeems to be a ſimple bag, holding the contents of the egg, and only united to them by ſome reflections of very fine membrane, which are chiefly attached to the back of the amnios, and in the courſe of the trunks of the blood-veſſels. This circumſtance has embarraſſed other obſervers, and has led many to overlook the ſhare that the veſicula umbilicalis has in the formation of the common membrane of the parts of the egg.

The *blood-veſſels* which are diſtributed to the external membrane are, even at the preſent period, much larger than thoſe of the yolk-bag. There are four long branches, which ſend out numerous ramifications, that become ſo minute as to evade the ſight; but when this membrane is viewed with a magnifying glaſs, it preſents a beautiful ſpectacle. The ſituation of the four great branches is not conſtantly the ſame; as they are diſperſed upon a looſe membrane, which varies in ſome degree its poſition according to circumſtances: one of them, if not two, is always ſeen, however, to croſs the back of the amnios. The four branches are arteries, and are formed immediately on the outſide of the umbilicus of the chick from the two iliac arteries; they, therefore, correſpond to the *umbilical arteries* of mammiferous animals. The left iliac artery is always of much greater ſize than the right; it even appears larger than the aorta, of which it is the termination.

nation. The right iliac artery is often a mere filament, and in ſome inſtances it ſeems to be wanting altogether.

The *venous branches* which accompany the umbilical arteries are ſo ſmall that they are hardly diſtinguiſhable, although the former are of ſufficient magnitude to be injected, and have a viſible pulſation. There is, therefore, a quantity of blood ſent to this membrane which is not returned to the fœtus. The colour of the blood, both in the umbilical arteries and veins, is a purple.

The vaſcular membrane, above deſcribed, has received different names. By the older anatomiſts it was uſually called the *chorion*, to which perhaps it is moſt analogous. Haller gave it the name of the *umbilical membrane*, and Leveille has lately called it the *bag-ſhaped membrane* (*membrane ſacciforme*), from the circumſtance of its enveloping all the parts of the egg. We have hitherto called it the *external membrane*, until it ſhould be deſcribed; but hereafter we ſhall ſpeak of it as the *chorion*. In the account of the unincubated egg, the membrane, on which the ſhell is moulded, is called the external, which it ſtrictly is. It ſhould not be confounded with the chorion, from which it differs ſo much in figure, ſtructure, and uſe. See Egg.

Haller appears to have not diſtinguiſhed the chorion from the membrane of the yolk-bag, which contains the vaſcular area. The progreſs of theſe two membranes is exceedingly different, and the ſyſtem of veſſels belonging to each is perfectly diſtinct. The valvular area is confined to the ſurface of the yolk-bag, and is intimately connected with its membranes, and the valvular apparatus already deſcribed. The veſſels of the area are chiefly venous, and are formed independently of the heart of the chick. They are moſt numerous in the early periods of incubation, although they increaſe in ſize along with the other parts of the chick. They go to terminate in a large vein which proceeds directly to the auricle of the heart in the firſt days, but, after the liver appears, is ſeen to paſs behind it, and when the inteſtines are formed is found upon the meſentery, and conſtitutes the largeſt branch of the vena portæ.

The arteries of the vaſcular area are inſignificant, until towards the end of incubation. When firſt perceived, they are given off from the dorſal aorta, and after the developement of the inteſtines they are diſcovered to be branches of the meſenteric artery. The veſſels diſtributed to the area appear, therefore, analogous to the omphalo-meſenteric arteries of quadrupeds, although their deſtination and functions may differ.

The *veſſels* of the *chorion*, as we have already ſaid, are branches, or rather, in the fœtal ſtate, the trunks of the iliacs extended upon this membrane. They do not exiſt previous to the appearance of the veſicula umbilicalis, with the growth of which they keep pace. The arteries of the chorion exceed the ſize of its veins in the ſame proportion as the veins of the yolk-bag exceed the arteries of that part. The vaſcular area, therefore, collects and tranſmits the blood to the fœtus, while the arteries of the chorion diſpoſe of a great portion of it in an extraneous circulation, and in the formation of a thick and extenſive membrane.

Haller and others have deſcribed, at this date, an appearance of white veſſels upon the albumen. Maitre Jan reckons ſeven of theſe white lines or veſſels. They ariſe from a little circle which is in the centre of the white; they divide into branches in advancing towards the vaſcular circle of the yolk-bag, which forms at this time the boundary of the ſeptum between the yolk and the white. Maitre Jan deſcribes them as paſſing beyond the ſeptum and extending to the yolk. Haller conjectures that the uſe of theſe veſſels may be to abſorb the white and convey it into the yolk. Obſerv. 226. Mem. 1.

We have not made ſuch an examination of theſe white lines, as to enable us to pronounce whether they are veſſels or not, or what their uſe may be.

The *water* of the *amnios* appears to diminiſh about this period of incubation. It alſo becomes gradually leſs pure. It is ſtated by Maitre Jan, that when the fluid of the amnios is boiled at this date, the greater portion of it acquires the hardneſs that the white of the egg poſſeſſes after being boiled, although previous to the experiment it is much more fluid than the albumen; from whence Maitre Jan conjectures that ſome of the fluid of the white is conveyed into the ſac of the amnios, but he does not pretend to explain the means by which this is effected.

The *curd-like ſubſtance*, already mentioned as being found in the ſtomach and inteſtines, is now met with alſo in the crop and œſophagus. According to Haller, boiling water makes this ſubſtance hard in the ſame manner as it does the white of an egg.

The end of 15 days, or 360 hours, the membrane of the *chorion* continues to increaſe in ſtrength, and its arteries in ſize. Haller ſpeaks of having ſometimes found the latter of a lighter red than the veins, which does not accord with our obſervations. We have generally perceived the arteries and veins to be ſimilar in colour, or at leaſt when a difference did exiſt it was immaterial, and ſometimes the arteries, and ſometimes the veins were the lighter coloured veſſels. The veſſels of the chorion have always appeared darker in our obſervations than thoſe of the yolk-bag, but the character of all the blood is venous in the incubated egg during the latter periods. The reflections of membrane which accompany the principal veſſels of the chorion, are now more firm than before, and continuous with them appears a fine tranſparent membrane that envelopes the yolk as far as the vaſcular circle on the edge of the white, and extends over part of the amnios, to which membrane it adheres, ſo as to cover an irregular triangular portion of the chick in its amnios, and incloſe more looſely the umbilical ſheath with the convolutions of the inteſtines which project from it and the neck of the yolk-bag. This membrane does not appear to have been well underſtood by the older anatomiſts.

They ſometimes ſpeak of it as a layer of the yolk-bag, and at others as the veſicula umbilicalis, or allantois. The beſt deſcription of it has been given by Leveille, who has alſo named it very appropriately *entero-clorilyme*, or *the membrane containing both inteſtines and yolk*.

The origin of this membrane is ſtill involved in a degree of obſcurity. Leveille deſcribed it when perfectly formed, but has thrown no light upon the hiſtory of its growth. The preſent date is the firſt at which it has appeared to us to be perfected, but we conceive that it is one of the original membranes and the ſecond layer, that in the firſt days comes off the vaſcular area as a very fine pellicle. It ſeems to be connected, or rather continued into the peritoneum, lining the abdomen in the late periods of incubation, of which we ſhall ſee farther proofs hereafter. There is no reaſon for ſuppoſing this membrane to be the veſicula umbilicalis, or allantois, as the veſicula is a ſtronger membrane in the middle of incubation than this membrane is ſeveral days afterwards, when it is completely formed. The proper contents of the allantois alſo are found, throughout incubation, within the cavity of the chorion, to the formation of which we have ſuppoſed that bag contributes, but never under the membrane that incloſes the inteſtine and yolk-bag.

Haller ſtates that he examined the *valves* upon the inner ſurface of the *yolk-bag* with a lens, and diſtinctly ſaw the inteſtiniform tubes upon the edges of the valves moſt beautifully curled and folded upon themſelves. He failed to ſee the aperture of theſe tubes. By maceration in water they were detached from the valves, and ſwam in the water. The valves themſelves, by a longer maceration, were alſo ſeparated.

The *chick* increaſes regularly in ſize, though not ſo rapidly as during the early part of incubation. Haller obſerved the feathers upon the *eye-lids* at this period, and that the *ſpleen* had acquired the figure it preſerves through life.

The *curdy*, or *coagulated ſubſtance* is now found in the œſophagus and the crop, as well as in the ſtomach and inteſtines. Harvey found this ſubſtance principally in the ſtomach: this appears to be the caſe, and when met with in other places, it would ſeem to have proceeded from the ſtomach to them.

The end of 16 *days, or* 384 *hours*, the ſpace between the two layers of the membrane lining the ſhell, for containing air, is much increaſed ſince the period at which we have laſt mentioned it. About one-ſixth of the whole cavity of the egg is occupied by air.

This circumſtance depends upon the diminution of the ſubſtance of the white, which is at preſent reduced to a very ſmall ſize.

The texture of the *white* continues to become firmer.

Upon removing the chorion, which now completely encloſes the white, that humour is found to poſſeſs a thin tunic, which is proper to it. This membrane is evidently of a late growth, and appears to be formed by the veſſels of the yolk-bag extending beyond the ſeptum, or that portion of the bag which is bounded by the vaſcular circle, and which is in contact with the white.

The fluid of the *amnios* is ſomewhat diminiſhed.

The *yolk-bag* in the egg of the hen is generally formed into three lobules, although many authors ſpeak only of two lobes at this time; one, which is the moſt diſtinct, but the ſmalleſt, lies upon the ſide of the body of the chick, between the head and the thigh: the two others are placed at the two ends of the chick.

Maitre Jan deſcribes the yolk-bag as being formed only into two lobes, but ready to enter the abdomen, of which he gives a figure at this period, and of a fiſſure that aſcends from the umbilicus, between the two recti muſcles of the belly of the chick. He likewiſe deſcribes the ductus vitello-inteſtinalis for the firſt time, which, with the yolk-bag, he ſucceeded in inflating from the crop of the chick; and he ſays this part is not to be demonſtrated at an earlier period than the end of the 16th day, on account of its extreme tenderneſs; but, as already mentioned, we have found the duct on the 13th day.

Haller found the inteſtines before this period to be irritable. When ſtimulated, they contracted into knots.

The blood-veſſels of the yolk-bag appear fewer and ſmaller, owing, in part, to their being ſo much more involved in the valvular coat than they were in the middle periods of incubation. The branches of the blood-veſſels of the yolk-bag are larger than the trunks, and the veins are ſtill vaſtly greater than the arteries. Haller ſtates that the vein going upon one of the valves, is a larger veſſel than the trunk, from whence all the arteries of the yolk-bag take their origin.

The End of 17 *Days, or* 408 *Hours.*—Haller admits the appearance of three lobes of the yolk at this date, which we have ſeen before.

The *arteries* of the *chorion* are extremely large; we have ſucceeded in introducing a pipe into them, and injecting them with coloured ſize, which makes a beautiful preparation. Haller, in his obſervation of this date, found both the arteries and veins of the chorion to be a purple colour, and the veins more violet than the arteries.

It now appears that there are two ſeries of veſſels belonging to the yolk-bag. The branches, which are ſpread upon the external membrane of the bag, appear to be the ſame which formed the vaſcular area in the early periods of incubation. The veſſels of the internal coat are diſtributed to the valves. Both ſeries contribute to the vaſcular circle, which, as we have before ſtated, is the remains of the vein that formed the contour of the vaſcular area. Maitre Jan ſays there are ſeveral layers of the membrane which contains the yolk, but it is probable that he miſtook for one that membrane which incloſes the yolk-bag, the inteſtines, and a part of the chick.

Coiter has found the *yolk-bag* within the belly of the chick at the 17th day; but the ingurgitation of the yolk is a later event, according to the obſervation of other writers.

There is now a circular arrangement of muſcular fibres around the opening into the belly of the chick at the umbilicus. This ſphincter was not apparent before, and, as we ſhall ſoon find, is a very eſſential ſtructure in the laſt periods of incubation.

If the *yolk-bag* be opened, and the valvular membranes cleaned by frequent ablution and floated in clear water, the ſides of the valves will be found to be perforated by a great number of foramina, ſo as to give the valves the appearance of lace. The inteſtiniform tubes alſo upon the edges of the valves will be partially detached; the portions that remain reſemble pieces of cylindric tubes.

Many of the blood-veſſels upon the external ſurface of the yolk-bag contain apparently but little blood, and have a greeniſh colour, as if conveying a yellow or green fluid.

The End of the 18*th Day, or* 432 *Hours.*—The two layers of the external membrane, which immediately lines the ſhell, are ſeparate for about one-third of their extent, and can with little pains be detached from each other until near the ſmall end of the egg. The quantity of air contained between theſe layers, although much increaſed, is leſs than might be ſuppoſed, as the layers are not far aſunder, except at the great end of the egg.

The *water* of the *amnios* is a good deal diminiſhed, and its membrane is applied in folds to the ſurface of the chick.

The *chorion* has attained a very conſiderable ſtrength, admitting of examination and diſſection, without being previouſly hardened by ſpirits or vinegar. When this membrane is laid open, there is ſome tough lymphy ſubſtance found under it in layers or ſtreaks, which has been miſtaken for a membrane by ſome anatomiſts. There is generally mixed with this ſubſtance a certain quantity of calcareous matter. It has, therefore, been ſuppoſed to be a kind of excrement, or the ſecretion of the kidnies. Theſe white flakes are what have been called *ſtriæ reticulatæ urinæ* by Malpighi, and were deſcribed by him as being found in the allantois.

When the chorion is opened and turned down off the contents of the egg, it appears to be a diſtinct bag, and only connected to the other parts by reflections of fine membrane. Theſe are chiefly in the courſe of the trunks of its blood-veſſels, and at the junction of the yolk and white.

The *yolk-bag* is now often found gathered into more lobules than three, ſome of which have entered the abdomen of the chick, through the aperture at the umbilicus. The forming of the yolk-bag into lobes and lobules, appears to be owing to the contraction of the membrane that contains it, and the inteſtines of the chick; for, when the yolk-bag is taken out of this membrane, it ſpreads out into nearly its original figure, except that there is a marked depreſſion where the white is joined with it, and that the neck of the bag is ſomewhat elongated. It ſeems likewiſe to be the contraction of the ſame membrane which urges the yolk-bag into the cavity of the abdomen of the chick.

The *yolk* appears to be ſomewhat leſs than in the preceding days; but on the cloſeſt examination we have not been able to diſcover any of it in the inteſtinal canal. We have obſerved at this period, although it probably exiſts much ſooner, an appearance of yellow veſſels accompanying on each ſide the blood-veſſels of the yolk in the ſame manner as the ſmall veins generally attend arteries. We have not been able to determine whether this appearance be cauſed by real veſſels filled with a yellow fluid, or by the inner coat of the bag being ſeen through the outer, producing on the edge of the tract of the real blood-veſſels an appearance of yellow lines.

The *chick* has now attained nearly the utmoſt ſize that it will poſſeſs while in the egg. Its form is entirely that of the excluded chick, except that its abdomen is enlarged in proportion to the quantity of the yolk-bag which is admitted into that cavity.

The different organs of the chick are very perfect. The convolutions of the *inteſtines* which were outſide are taken into the belly with a portion of the yolk-bag, as before mentioned. Maitre Jan ſtates that he found about this period the *tympanum* and the *labyrinth* of the *ear* hard, and nearly of their full ſize. All the *bones* have acquired oſſeous matter and conſiderable hardneſs.

The *bile* contained in the *gall-bag* is an intenſe green, and gives that bag a blue colour.

The end of the 19*th day, or* 456 *hours*, the *air-cell* extends round one-half of the cavity of the egg.

The *amnios* is in ſome inſtances found to be ruptured by the bill of the chick.

According to Haller, the chick begins to cry about this period. Harvey and Langly alſo heard the piping of the chick at this date. Some other authors have not noticed the chick to cry until the twentieth day, which agrees with our obſervations. Still, however, the time at which the chick begins to cry is ſubject to vary, according to the degree of heat to which it is expoſed. Thus, in an egg from which no ſound iſſues while it is in the neſt, if placed upon warm water the piping of the chick will be heard.

The *chorion* begins to appear a little faded, the circulation of blood upon the membrane being carried on more ſluggiſhly. This change ſeems to be preparatory to the deſtruction of that membrane which is about to happen.

More than two-thirds of the *yolk-bag* and its contents have been received into the abdomen. If that cavity be opened, it will be ſeen that the bag is preſſed in amongſt the different viſcera, to which its figure is capable of being perfectly accommodated in conſequence of its folds and lobules.

The *white* is reduced to a few irregular-ſhaped knots, which generally contain ſome calcareous matter that appear to remain after all the liquid parts of the albumen have been removed. The knots are compoſed of the chalazæ, and the membrane of the white compreſſed together.

Maitre Jan very readily ſucceeded in diſtending the yolk-bag and the ductus vitello-inteſtinalis, by blowing air into the œſophagus, but did not yet perceive that any of the yolk had paſſed through the duct into the inteſtine.

Haller deſcribes at this date the effects produced upon the valvular ſtructure of the yolk-bag by maceration in water for ſome days.

Having firſt waſhed the ſac containing the yolk with ſeveral waters, he found the edges of the valves covered with the vermiform tubes before deſcribed, which ſeparate and form curves; theſe elongate and expoſe the interval of their two curvatures. They break at the end, and the two ends become nearly ſtraight, remaining attached to the edge of the valve. The breadth of theſe little membranes appears alſo covered with cylindric tubes, ſometimes branched and ſeparated by the reticular intervals. The day after, the yolk-bag having been ſteeped in water, he ſaw the appearance of cylindric tubes forming a net-work upon the membrane which makes the breadth of the valves, and continuous with the vermiform tubes of the edges. He further ſaw that the veſſels of the valves, having arrived there, were covered with ſome very fine ſmall tubes reſembling a powder. The following morning, he ſaw ſome of the tubes which aſcended from the baſe of the valves, and which were continued with the tubes of the edge. They were cylindric as far as he could perceive, and joined in form of a net-work. The ſtraight veſſels went evidently as far as the vaſcular circle of the yolk-bag.

The fourth day many of the tubes had diſappeared, and there only remained on the edge of the valves the membrane which covered the trunk of the veſſel. With reſpect to the nature of the tubes on the ſides of the valves, he found it difficult to pronounce with certainty. By examination with a ſtrong lens he perceived that there were ſome real tubes upon the ſides of the valves, which aſcended in a ſerpentine manner; but thoſe which are the moſt numerous, and which form the net-work on the breadth of the valves, were not determined to be tubes, although they are moſt probably ſo, as they appear cylindric under every point of view, and are continuous with the tubes of the edge.

The fifth day, the veſſels of the edge appeared all uncovered: theſe veſſels preſerved ſome breadth, and a round figure at the edge, and an undulating courſe. It was more eaſy to diſtinguiſh the real veſſels which deſcend from the edge in a ſerpentine manner, and traverſe obliquely the breadth of the membrane, in order to return into the plain between the valves. Haller alſo ſaw very evidently ſome branches which proceed from the veſſels between the valves, and which aſcend in a ſerpentine manner by the ſide of the valves, and communicate with the trunk which runs along the edge. The remainder of the valve was become an open net-work of extreme beauty.

The ſixth day many of the valves had diſappeared, and others preſented only a plaited border, like a meſentery, from which the inteſtines had been removed. Mem. 1. p. 379.

The *chick* at the preſent date is about the ſize that it is immediately after excluſion from the ſhell. It lies coiled round with its head under the right wing.

The *blood-veſſels* in the interior of the chick have attained more of their proper ſize in proportion to the parts they ſupply. The left branch of the aorta, however, which forms the principal umbilical artery, is ſtill nearly equal in magnitude to the aorta itſelf.

Haller obſerved at this period the *vena cava* beat between the lobes of the liver.

The end of the 20*th day, or* 480 *hours*, the *ſhell* is extremely dry, and very fragile, which is occaſioned by the more extenſive detachment of the membrane which is immediately under it. The brittleneſs of the ſhell is a very convenient circumſtance at this period, when it is about to be ruptured by the efforts of the chick.

It is uſual at the preſent date to find the greater number of the eggs in a hen's neſt cracked or chipped near the great end. This is attributed by common people to the parent, who is ſuppoſed, by a particular inſtinct, to know the proper period for the liberation of the young chick. Malpighi likewiſe ſuppoſed that the ſhell was broken by the hen, in which opinion Haller ſeems to concur. He ſtates that he found a fiſſure in the ſhell, and the membranes which incloſed the chick, at the ſame time entire. Maitre Jan, on the contrary, aſcribes the fracture of the ſhell to the chick. He found the beak had lacerated the membranes before the ſhell was broken; and having watched the eggs at the time the chicks began to cry, he did not perceive the hen touch them with her bill, but that the ſhell was ruptured from the inſide, and the fractured portions were puſhed outwards. This account of the mode in which the ſhell is opened, exactly accords with our obſervations. We have ſeen the ſhell evidently broken from within; beſides, the fact of birds being hatched by artificial heat, proves decidedly, that the aſſiſtance of the hen is not neceſſary for the fracture of the egg.

After the ſhell is broken the chick is always heard to cry, and the point of its beak is ſeen to project out of the egg for ſeveral hours before the chick attempts its liberation.

It is reported by common people who have the care of ſitting hens, and it is even aſſerted by ſome anatomiſts, that the cries of the chick are heard before there is any aperture made in the ſhell. Haller relates that he took an egg, in which he diſcovered the piping of the chick, and which was at the ſame time unbroken, and having carefully removed the ſhell, piece by piece, he found that the opaque membrane, which lines the ſhell, was alſo entire, but that there was an opening in the chorion oppoſite to the beak of the chick. He does not ſtate whether the bill had penetrated into the air-cell, but it moſt probably did, as at this period the two layers of the membrane lining the ſhell are ſeparated beyond the ſituation of the beak of the chick. In another obſervation Haller found the chorion entire under the fiſſure in the ſhell, which was on the oppoſite ſide of the egg to the bill of the chick; and therefore he ſuppoſes the ſhell to have been cracked by the hen. We cannot poſitively contradict the aſſertion of the chick uttering ſound before it has the means of freely reſpiring, but we ſhould conceive it extremely improbable; and upon every occaſion where we have heard the piping of the chick iſſue from the egg, we have found that there was a crack or fracture in the ſhell.

Where the chorion is lacerated by the beak of the chick there is always ſome blood ſhed, but the edges of the membrane ſoon dry, which prevents any farther hæmorrhage; for the circulation is not yet interrupted in the chorion by the contraction of the ſphincter at the umbilicus, although Maitre Jan deſcribes the paſſage of the yolk, and the deſtruction of the chorion, as events of the ſame date.

When incubation has proceeded regularly, the whole of the yolk-bag at this period is found within the cavity of the abdomen, which is cloſed by the contraction of the circular faſciculus, of muſcular fibres placed around the umbilicus; but, as already mentioned, this does not, until near the excluſion of the chick, compreſs the umbilical veſſels, ſo as to deſtroy their circulation.

The ingurgitation of the yolk cauſes a great tumefaction of the belly of the chick. The animal reſembles one in a gravid ſtate, but the belly is leſs ſwollen than might have been ſuppoſed from the bulk of the yolk-bag. The latter does not lie in the front of the cavity, but is preſſed in between all the viſcera, and therefore occupies the leaſt poſſible ſpace.

It is remarked by Maitre Jan, that more chicks die about this period than at any other of incubation, which he attributes to the diſtention of the abdomen by the yolk-bag; but we ſhould ſuppoſe that it is the ceſſation of the external circulation upon the membrane of the chorion, which cauſes the great fatality towards the end of incubation.

Maitre Jan ſtates that he diſcovered the fluid of the *yolk* at the 484th hour mixed with the contents of the ſmall inteſtines; but ſome other anatomiſts, who admit the paſſage of the yolk through the ductus vitello inteſtinalis, do not pretend to have detected it in the inteſtine ſo early.

The *chick*, about this period, is ſometimes obſerved to remain for a while perfectly motionleſs. Harvey ſuppoſed that it was aſleep on theſe occaſions. How far he was correct we cannot pretend to ſay.

According to Haller the weight of the yolk is not ſenſibly diminiſhed before its entrance into the belly of the chick. He weighed the entire yolk-bag at the 500dth hour, and found it to be three drachms and two grains. He ſtates that the weight of the yolk, before incubation, was three drachms and ten grains. This diminution of weight is, therefore, not greater than might have been expected from evaporation, or from an original difference in the bulk of the two eggs that were the ſubjects of the experiment.

Haller, in ſeeking for the *allantois*, or *veſicula umbilicalis*, at this period, ſtates, that he could not diſtinguiſh it from the chorion, or rather from a fine membrane he raiſed from the internal ſurface of the chorion by inflation; but he found a little ſac in the form of a pear, extremely vaſcular, full of a yellow mucus, and terminated by a peduncle which was not an inch long. We have already deſcribed the veſicula umbilicalis as being loſt in the formation of the chorion long before the preſent period. Malpighi, likewiſe, ſuppoſed this part to have the ſame deſtination in the latter periods of incubation: and in none of our obſervations have we met with the pear-ſhaped bag mentioned by Haller. We have turned back the chorion at the preſent date, and have found it to be a perfect ſac, ſuch as we have previouſly deſcribed it, and connected with the adjoining membranes by reflections of a very delicate texture. Theſe were readily detached, and left the chorion pendent by its veſſels from the umbilicus of the chick. Beſides the blood-veſſels, we could diſcover a tranſparent filament paſſing to the inverted bag, which appeared to be tubular, and perhaps was the urachus.

The End of 21 *Days, or the full Period of the Incubation of the Hen.*—When the progreſs of incubation has been regular, the chicks are now generally found to have abandoned the eggs, leaving the ſhells with the ſhreds of the chorion and amnios behind them. It happens, however, occaſionally, that ſome of the chicks have been backward in their growth, from the unfavourable poſition of the eggs in the neſt, or the negligence of the hen. Theſe are ſometimes found about this period within the broken ſhell, having the remains of the membranes ſtill attached to the umbilicus.

The ſeparation of the membranes does not appear to be effected by a proceſs of ſlough or of ulceration. They appear rather to be torn off, as ſome ſhreds and a ſhort portion of the trunks of the blood-veſſels are ſeen to project at the umbilicus. The hemorrhage from theſe veſſels alſo is not entirely ſuppreſſed by the conſtriction of the ſphincter muſcle, but in a degree by the aſſiſtance of a clot of blood, which forms in the ends of the torn veſſels.

We have not been able to obſerve whether the complete fracture of the ſhell, previous to the excluſion of the chick, and the detachment of the membranes, are accompliſhed by the efforts of the chick alone, or with the aſſiſtance of the hen.

The belly of the chick, after excluſion, is much enlarged, though leſs tumid than it was when the yolk-bag was firſt taken into the abdomen. It would, therefore, appear that the yolk begins to diminiſh immediately after it is admitted into the belly of the chick, although ſome obſervations of

Haller would lead to a different concluſion. He weighed the egg and its different contents at the 526th hour, and found the entire egg to be 13 drachms and as many grains; the weight of the yolk, with ſome light membranes that adhered to it, was four drachms. The fœtus weighed five drachms and 14 grains. In an egg which had not been ſat upon, he found the weight of the entire egg to be 10 drachms and three-ſixths, and that of the yolk three drachms and 10 grains. This account of the weight is obviouſly incorrect. See EGG.

Many anatomiſts ſtate that they have been able to detect the fluid of the yolk in the inteſtines at this period, and ſome ſuppoſed that they found it had paſſed into the alimentary canal, even before the excluſion of the chick. Haller found yolk in the inteſtines at the end of the 21ſt day, in one inſtance where the chick had not left the egg. Maitre Jan ſaw it after 20 days and ſix hours. Needham deſcribes the gradual paſſage of the yolk into the inteſtine at the end of incubation. Langly alſo found it in the inteſtine at the ſame time. Theod. Aldes ſtates that before the chick was excluded, he could not preſs the ſubſtance of the yolk into the gut, but that immediately afterwards he was able to do ſo. Stenon ſucceeded in preſſing the yolk through the ductus vitello inteſtinalis.

Notwithſtanding the teſtimony of ſo many anatomiſts, we are inclined to believe, that the ſubſtance of the yolk is not conveyed into the inteſtine. We have ſcrupulouſly examined the inteſtines of chicks, both before and after the excluſion from the egg, and in no inſtance could we diſcover with certainty any yolk in them. In the laſt periods of incubation, and until the chick has taken its natural food into the ſtomach, the alimentary canal is filled with a yellow fluid, which it is ſcarcely poſſible to diſtinguiſh from the yolk; therefore, all direct obſervations reſpecting the paſſage of the yolk into the inteſtines muſt be attended with a degree of doubt. There are, nevertheleſs, many reaſons beſides actual examination; for ſuppoſing that the yolk is not conveyed into the ſyſtem of the chick by paſſing firſt into the inteſtinal canal, which we ſhall ſtate in ſpeaking of the uſes of the different parts of the egg, we are further ſupported in our opinion by the authority of Blumenbach, who aſſerts poſitively, that the yolk does not paſs into the inteſtine. We might alſo quote the ſame opinion held by Leveille; but he advances it upon falſe grounds, as he deſcribes the ductus vitello inteſtinalis as a ligament, by which the yolk-bag is ſuſpended to the body of the chick, notwithſtanding the tubular ſtructure of this part is ſo palpable.

The ſubſtance of the yolk at the end of incubation is extremely tenacious or gluey in its conſiſtence, and of a deep green colour, particularly in the centre.

The net-work of the valves upon the inner membrane is very viſible at this period. We have thrown coloured ſize into the blood-veſſels of the yolk, and afterwards ſoftened by maceration, and by frequent ablution detached the inner membrane; when we found that the baſis of the lace-like or reticulated ſtructure of the valves was formed by real blood-veſſels, which preſented the moſt beautiful vaſcular apparatus that we have ever ſeen. This mode of preparation ſhews, that the organization of the internal membrane depends upon the growth of the blood-veſſels of the external membrane of the yolk-bag, and confirms the account we have already given of the formation of the valves. Haller conſidered the veſſels diſtributed in the valvular ſtructure of the bag as being chiefly, if not entirely, venous; but we found them moſt eaſily injected from the aorta of the chick. In the early periods of incubation we know that the branches of the veins of the yolk-bag are larger and more numerous than thoſe of the arteries, but we are inclined to believe the arterial branches predominate towards the end of incubation. Further obſervations, however, are neceſſary to explain the vacſular ſyſtem of this membrane.

Several anatomiſts ſpeak of a new membrane being found upon the yolk-bag towards the end of incubation, which is continuous with the ſkin of the chick. Haller, in ſome obſervations, deſcribes this membrane in a manner which leaves no doubt of its being the ſame that we have already noticed as including the yolk-bag and inteſtines of the chick, when they are on the outſide of the body.

We, as well as others, have found the appearance of a new tranſparent membrane covering the yolk-bag after it has entered the abdomen of the chick. This membrane ſeems to be the continuation of the peritoneum. It adheres to the inſide of the umbilicus, and to that point of the yolk-bag where the white and chalazæ were attached. We have not had it in our power to inveſtigate completely the connections of the yolk-bag with the peritoneal coat of the parietes of the belly, but we believe at preſent that any appearance of a third tunic to the bag is derived from the peritoneum.

Haller ſtates obſervations made upon the *allantois* or *veſicula umbilicalis*, even to the laſt day of incubation. He mentions that he found under the chorion an extremely fine membrane which was incorporated with the tiſſue of white filaments or ſtreaks that we have ſpoken of before. He deſcribes this membrane as giving an immediate covering to the chick: it was ſo tender that inflation burſt it. He ſuppoſes it to be either the amnios or the allantois. In the next paragraph he ſays, he ſought the centre of the yolk, and found the urachus there without having any connection with the allantois. He inflated it, one part of the air went out at the anus; another elevated the membranes of the rectum. He next paſſed an extremely fine probe into the urachus, and found an orifice on the left ſide, between the anus and that veſicle that the urachus produced by inflation in the rectum: the probe would not enter the plicated muſcular ſac, which is behind the rectum and at the ſide of the vagina.

This account appears to us to be very inaccurate in ſome points. The membrane which Haller took for the allantois was moſt probably that which envelopes the yolk-bag and inteſtines. The urachus at the periods of incubation, when it can be found, has no connection with the yolk-bag. The foramen on the left ſide of the anus appears to have been made by the probe, and the muſcular ſac he ſpeaks of was the burſa Fabricii.

Changes which take place in the Structure of the Chick after Incubation.—Theſe chiefly relate to the diſappearance of the yolk, and the degeneracy of the arterial ducts, which in the fœtus conveyed the blood from the pulmonary artery into the aorta.

In two days after excluſion from the egg, the *yolk* is very ſenſibly diminiſhed in quantity, and its conſiſtence is even more tenacious or gluey than it was before.

The *right ductus arterioſus*, which is the firſt obliterated, becomes as ſmall as a filament. The *left* is, according to Haller, diminiſhed three times the ſize it had during incubation.

In four days after excluſion, the *yolk* is found to be reduced two-thirds of its bulk. In proportion as the ſubſtance of the yolk diſappears, the membranes forming the bag alſo diminiſh. The adheſion which we have mentioned the yolk-bag to have with the internal part of the umbilicus, after its admiſſion into the abdomen, is now undone. It would appear that this attachment is produced by the contraction of the ſphincter muſcle upon the remnant of the veſſels and of the membranes connected with the centre of the yolk-bag.

It is now particularly eaſy to ſee the origin and courſe of the proper *blood-veſſels* of the yolk. The *veins* belong to a ſingle trunk, which is continued along the meſentery, and ends in the vena portæ; it is evidently a branch of the meſenteric vein. The *arteries* are alſo derived from a ſingle trunk, which is the principal branch of the meſenteric artery. This trunk, in ſome points of view, appears to be double; it divides, paſſes on each ſide of the inteſtine, and then unites to form a ſingle veſſel previous to its diſtribution in the membranes of the yolk-bag. Theſe veſſels, and the ductus vitello inteſtinalis, are connected together by ſome fine folds of peritoneum, which are the continuation of the meſentery.

The cavity of the *right ductus arterioſus* is completely obliterated, but the *left* is ſcarcely more diminiſhed than it was on the ſecond day.

In eight days after excluſion, the *yolk* is reduced to the ſize of a hazel nut. The *ductus vitello inteſtinalis* becomes thicker, and more reſembles the inteſtine than it did before.

The valvular ſtructure upon the internal ſurface of the yolk-bag is no longer apparent.

The *right ductus arterioſus,* although reduced to the ſize of a filament, is enlarged where it enters the aorta.

The left *duct* is likewiſe obliterated at its origin from the pulmonary artery; it is a filament, but is inferiorly white, opaque, and larger. Both theſe ducts, therefore, decline firſt at the ſuperior part, where they come from the pulmonary artery.

The *gizzard* of the chick, eſpecially if the animal has had the opportunity of picking up ſmall ſtones with its food, is thick and muſcular; and the internal coat, which during incubation was ſoft and ſpongy, is now become firm and dry.

In 16 *days after excluſion,* according to Haller, the ſubſtance of the *yolk* is entirely conſumed; there remains but a ſmall thin ſac, leſs than a pea, containing a granular ſubſtance, which is partly of a calcareous nature, and which is the dregs of the ſubſtance of the yolk.

Twenty-ſeven days after excluſion, Haller found both the *right ductus arterioſus,* and the left, ſtill remaining in the form of filaments. The right was ſmaller than the left. The latter was ſtill open at its junction with the aorta.

In three months after excluſion, the *ductus vitello inteſtinalis* is found to be turned down upon the ſide of the inteſtine, to which it evidently forms an appendix. At its extremity may ſtill be ſeen the remnant of the yolk-bag, reduced to nearly the ſize of the head of a pin. It is uſually dark coloured, from the nature of its contents.

In the adult bird, Stenon, Needham, and Maitre Jan, have recognized the *ductus vitello inteſtinalis* in the form of a ſmall cæcum. It is ſituated on the alimentary canal, about midway between the ſtomach and the anus.

Needham deſcribes it as being half an inch long, but this is incorrect with reſpect to any of the *gallinaceous* tribe, but in ſome other birds we have found it of a very remarkable ſize.

In the *ſnibe* it exceeds in length the cæca of the large inteſtine.

In the *curlew* it is about an inch long, and very capacious.

In the *woodcock* it is nearly as large.

It is above an inch long, and very ſlender, in the *black coot*: the cæca of the great inteſtines are alſo ſingularly long and ſlender in this bird.

In all the paſſerine birds it is ſmall.

In the *ſwan*, *gooſe*, and *duck* it is of a moderate ſize.

It is remarkably ſmall in the *heron* and in the *hawk.*

In all the birds we have examined, there exiſts during life ſome remnant of the yolk-bag at the end of the cæcum, formed by the ductus vitello inteſtinalis. This is more particularly remarkable in the *paſſerine* and *accipitrine* birds. The *nightingale* has a little ſac, about the ſize of a ſmall pea, attached to the end of this proceſs of the inteſtine.

Although there is ſo much variety with reſpect to the figure and ſize of the cæcum of the ſmall inteſtines of birds, the ſtructure of this part is conſtantly the ſame in every ſpecies. It appears to poſſeſs but two coats; one is the continuation of the peritoneum, covering the inteſtine: the other correſponds to the mucous membrane of the gut. The internal ſurface of the cæcum exhibits ſmall cells ſimilar to thoſe points of the alimentary canal on which the mucous glands are congregated. This ſtructure exiſts whether the internal membrane of the inteſtine be plicated or villous.

We have not found the appendix produced by the ductus vitello inteſtinalis to receive, in any inſtance, the contents of the alimentary canal. It is filled with a mucous fluid, which appears to be ſecreted from its internal ſurface. There is, therefore, every reaſon to ſuppoſe that this appendix performs the office of a mucous gland in the adult bird. The great ſize which it poſſeſſes in the *ſnipe*, *curlew*, *woodcock*, and *coot* is probably dependent upon the nature of the food of theſe birds, although we cannot at preſent perceive in what manner this part is ſo particularly uſeful to them. See Phil. Tranſ. part ii. 1811.

In the *Plate* deſigned to illuſtrate the incubation of the egg, *fig.* 1. exhibits an egg with a portion of the ſhell and the membrane underneath it, removed at the great end: *a* is the firſt appearance of the fœtus as it is ſeen in the cicatricula, through the membrane which covers it; around it are the concentric circles or waves (*halones*).

Fig. 2. repreſents an egg opened in the ſame manner in order to expoſe the fœtus when it is a little more advanced, with the commencement of the vaſcular area; *a*, the fœtus ſomewhat formed with the head like the top of a club; *b*, the contour of the vaſcular area aſſuming the heart-ſhape: it does not yet circulate red blood, but within it are ſeen the rudiments of veſſels containing a greeniſh fluid. Some of theſe points are of a darker colour, and are the firſt appearance of the real blood.

Fig. 3. is an egg alſo with the ſhell of the great end removed; *a* is the fœtal chick; *b* refers to the pulſating points that conſtitute the heart; *c* repreſents the appearance of the vaſcular area after the circulation of blood is perfected in it.

Fig. 4. exhibits a magnified view of the portion of the membranes at the great end of the egg, including the chick and vaſcular area about the fourth day of incubation; *a* is the thin gliſtening membrane which readily ſeparates at this period from the reſt, turned back; *b* is the fine tranſparent membrane immediately under the firſt, alſo turned a little off; *c* the chick contained in the amnios; *d* the veſicula umbilicalis attached to the chick; *e* the external membrane of the yolk-bag on which the veſſels compoſing the vaſcular area are ſeen to ſpread; *f* is the internal pulpy membrane of the yolk-bag which afterwards produces the valves, the preceding membrane being partially removed to expoſe it.

Fig. 5. exhibits a portion of the yolk-bag with the chick and veſicula umbilicalis conſiderably magnified; *a* the chick; *b* the amnios; *c* the membranous connection the amnios has with the veſicula umbilicalis; *d* the veſicula, the neck of which is ſeen to enter the opening at the umbilicus of the chick.

Fig. 6. is a magnified view of the heart of the chick as it appears when firſt formed ; *a* indicates the horſe-ſhoe dilatation mentioned in the deſcription of that organ on the ſecond day.

Fig. 7. ſhews the heart and large veſſels of the chick magnified after theſe parts are more perfectly formed ; *a* is the vena cava ; *b* the auricle ; *c* the auricular canal ; *d* the ſingle ventricle ; *e* the bulb of the aorta ; *f* the principal artery.

Fig. 8. is a view, alſo magnified, of the heart, pulmonary arteries, lungs, and aorta of the chick ; *a* is the heart ſeen on the poſterior ſide ; *b*, *b*, the two arteries which ſend off the pulmonary arteries, and afterwards concur towards the formation of the abdominal aorta. Theſe veſſels, after parting with their branches to the lungs, are analogous to the ductus arterioſus of mammalia ; *c*, *c*, are the pulmonary branches of the veſſels laſt mentioned ; *d* the third veſſel of the heart, which correſponds to the ſuperior part of the aorta ; *e* the abdominal aorta, formed as already deſcribed ; *f*, *f*, the two lungs.

Fig. 9. is a view of the internal ſurface of the yolk-bag after the valves have begun to form upon it.

Fig. 10. ſhews a ſimilar view of the internal membrane of the yolk-bag, when the valvular apparatus is completely formed ; *a*, *a*, *a*, indicate ſome of the inteſtiniform tubes upon the edges of the valves ; *b*, *b*, the appearance of veſſels in the intervals between the valves. The valvular projections themſelves are ſufficiently evident.

Fig. 11. ſhews a portion of one of the valves of the yolk-bag magnified ; *a* the baſis of the valve, where the principal veſſel runs ; *b* the plaits or folds upon its ſide ; *c* the inteſtiniform tubes upon the edge of the valve.

Fig. 12. is a magnified view of a portion of a valve of the yolk-bag after it had been converted into a fine lace, the veſſels injected, and the internal membrane waſhed, ſo that the real blood-veſſels alone remain ; *a* is the principal veſſel that runs along the baſe of the valve ; *b* the one which goes along the free edge ; *c* the lace-like ramification of veſſels between theſe two.

Fig. 13. repreſents the yolk-bag, and the portion of the inteſtine with which it is connected, taken out of the chick a few days after incubation ; *a* is the yolk-bag very much reduced in ſize, and of an irregular form ; *b* the piece of inteſtine to which the yolk-bag is attached ; *c* the ductus vitello inteſtinalis imperfectly ſeen, as it is partly covered by the blood-veſſels of the yolk-bag ; *d* the branch of the meſenteric vein, which furniſhes, in the early periods of incubation, the veins of the vaſcular area ; *e* the branch of the meſenteric artery, which goes to the yolk-bag. It divides, paſſes on each ſide of the inteſtine, and unites again before it ramifies upon the yolk-bag.

Fig. 14. ſhews the chick after the yolk-bag had been taken into the belly ; *a* the umbilical opening ſurrounding the aperture, which is cloſed, in the preſent inſtance, by the contraction of this muſcle ; *b* ſome lacerated veſſels, and a portion of the chorion hanging from the umbilical aperture ; *c* the belly of the chick diſtended in conſequence of the admiſſion of the yolk-bag.

Fig. 15. is a plan of the relative poſition and magnitude of the contents of the egg about the ninth day of incubation. The view is procured by firſt boiling the entire egg, and afterwards making an equal ſection ; *a* the edge of the ſhell ; *b* the cavity left between the two layers of the membrane that lines the ſhell to contain air. This cavity is conſiderable at the preſent period ; *c* the chick in its amnios ; *d* the yolk ; *e* the cut edge of the yolk-bag ; *f* the white which has deſcended to the ſmall end of the egg and diminiſhed ; *g* the chalazæ, much nearer each other than they were before incubation.

Fig. 16. exhibits a view of the contents of the egg, with the chorion cut open and turned down off the other parts ; *a* the chick ſeen obſcurely, as it is in ſome meaſure covered by the membrane that includes the yolk-bag and inteſtines, beſides being ſurrounded by the amnios, the fluid of which, at the preſent period is greeniſh ; *b b* the amnios ſeen at each end of the chick ; *c* indicates the yolk-bag, which is divided into three lobes ; one of them is ſeen to lie upon the ſide of the chick ; the blood-veſſels of the yolk appear ſmall, and are indiſtinctly ſeen ; *d* ſome folds of the membrane which invelopes the yolk-bag, inteſtines, and a part of the chick ; *e* the white contained in its proper membrane, and very much reduced in ſize ; *f* the chorion turned down, and therefore the ſurface that is ſeen is the internal ; *g*, *g*, *g*, reflections of fine membrane which attach the chorion to the other membranes ; *h*, *h*, the two trunks of the umbilical arteries, which each divide into two branches, and are diſtributed to the chorion.

Fig. 17. is intended to explain the formation of that membrane which includes the yolk-bag and the inteſtines of the chick, and for this purpoſe the chorion is intirely removed ; *a* is the chick contained in the amnios ; *b* indicates the membrane of the yolk-bag and inteſtines ; it is ſeen to cover a certain extent of the amnios and chick ; it deſcends poſteriorly to be connected to the ſeptum, between the yolk-bag and the white : anteriorly it is laid open, in order to turn out the yolk-bag, which was before contained in this membrane. Within the chink made by the inciſion are to be ſeen the inteſtines of the chick perfectly uncovered and deſignated by *c*. The yolk-bag hangs by the ductus vitello inteſtinalis and its blood-veſſels, and is marked by the letter *d*.

Fig. 18. ſhews an egg with the great end fractured previous to the excluſion of the chick : ſome more pieces of the ſhell are removed in order to bring into view the membranes that are lacerated by the bill of the chick ; *a* is that portion of the membrane under the ſhell which forms the air-cell, and in which there is a ſmall aperture. The chorion and amnios are torn to a greater extent to permit the bill of the chick to appear on the outſide of the ſhell ; *b* the bill of the chick : beſide it are ſeen ſome points of feathers projecting out of the opening made in the outer membrane.

Fig. 19. is a portion of the ſmall inteſtine taken from the adult bird, on which the appendix is placed, that we have deſcribed as the remnant of the ductus vitello inteſtinalis ; *a* the inteſtine ; *b* the appendix or cæcum ; *c* is a little knot which was, during fœtal life, the yolk-bag.

In ſome of the preceding figures, the form of the chick is repreſented at different ages, which the reader will underſtand without the letters of reference.

Of the Uſes of the different Parts of the Egg during Incubation, and after the Excluſion of the Chick.—Although there can be no doubt that the chick derives its nutriment from the humours of the egg, the mode in which this is effected is involved in conſiderable obſcurity. Anatomiſts have entertained very different opinions upon the ſubject. Some have ſuppoſed that both in mammiferous animals and birds, the fœtus is nouriſhed by ſwallowing or abſorbing the liquor amnii.

Heiſter, in his Compendium of Anatomy, ſtates, that after the contents of the uterus of the *cow* were frozen, he found a piece of ice of the thickneſs of a finger extended from the congealed amnios into the mouth of the fœtus, and down the œſophagus as far as the ſtomach.

There have been ſometimes ſeen alſo in the ſtomach of the *fœtal calf* the ſame kind of fatty concretions, that uſually exiſt in the amnios of this animal. The hairs of the *calf* have been diſcovered in the meconium. New-born infants have been obſerved to vomit a fluid reſembling the liquor amnii.

It has been remarked by Harvey, Haller, and ſeveral other writers upon incubation, that the fœtal chick frequently opens and ſhuts its mouth while incloſed in the amnios, as if it were performing the act of ſwallowing.

The preceding facts leave no doubt that the water of the amnios paſſes into the ſtomach of the fœtus, but by no means proves that it contributes to the nouriſhment of the young animal, but rather the contrary, as if it were either digeſted in the ſtomach, or conſumed by abſorption, it could not be found towards the end of geſtation, or afterbirth, in the quantity reported.

Thoſe who give credit to the nutrition of the fœtus by the liquor amnii, cite ſome remarkable caſes in which the umbilical cord is ſaid to have been deſtroyed before birth, or in which the infant has been born with the cicatrix at the umbilicus perfectly formed. See Obſerv. rarior cent poſt pars 1. obſ. 32.—Journal des ſavans, année 1673, p. 69. Obſervat. communiq. par Chatton.—F. Hoffmann & Triller Diſſert. de pinguid e ſucco nutr. ſuperfl. p. 10. and Rommel Ephemer. nat. cur. dic. 2 à 7, obſ. 209.

It ſhould be remarked, that of theſe obſervations, ſome are related in a manner which makes their accuracy very doubtful; and others, even if correctly ſtated, do not prove the point they are propoſed to eſtabliſh. Thus the infant with the cicatrized navel was not ſeen by Chatton until five months after birth; and in ſome of the caſes where the cord was ſaid to be injured or putrid while the child was alive, it does not appear that the circulation had been deſtroyed.

We ſhould not have noticed the doctrine of the nutrition of the fœtus from the liquor amnii, as it is generally diſcredited, had it not been advanced with ſome limitation by Lobſtein in a modern publication. This author does not pretend that the fœtus ſwallows the liquor amnii, he allows that the young animal exiſts and increaſes in growth, before the digeſtive organs or even the mouth are formed. He is alſo aware, that there have been monſters produced in whom the head was wanting. He therefore ſuppoſes, that the fluid of the amnios is taken into the body of the fœtus by the abſorbents of the ſkin, which opinion he grounds upon the following circumſtances: Many of the cold-blooded animals, he ſays, have no placenta, but in every ſpecies the fœtus floats in a clear liquor, analogous to that of the amnios. This fluid, he remarks, diminiſhes in proportion to the growth of the fœtus; it likewiſe remains uncorrupted during fœtal life, which fact, he thinks, can only be explained by its paſſing ſucceſſively into the body of the young animal. (Lobſtein ſur la Nutrition du Fœtus, § 88.) Our reply to this reaſoning would be, that the liquor amnii is not a nutritive fluid perhaps in any inſtance; that when firſt perceived, it is in a very ſmall quantity: it is, in the higher claſſes of animals, contained in a membrane which is continuous with the ſkin of the fœtus, and which membrane further derives its blood-veſſels from the fœtus. It is, therefore, a ſecretion of the young animal. During ſeveral days of incubation it increaſes as the chick grows, and in the latter periods does not perhaps actually diminiſh in quantity, but ceaſes to increaſe in proportion to the developement of the chick; for which reaſon it appears leſs than it did when the chick was ſmall. The quantity of the liquor amnii at any given time, even admitting that it is not ſecreted by the fœtus, would be quite inſufficient for the formation of the latter. The principal part of this fluid alſo is loſt when the membrane that contains it is ruptured, previous to the liberation of the young animal from the uterus or the egg. We ſhould, on all theſe grounds, deny that the liquor amnii is deſtined to ſuſtain the fœtus in any circumſtances.

In all oviparous animals, there is no neceſſity for ſuppoſing the liquor amnii to be a nutritive fluid, as there are other humours provided for the purpoſe of nouriſhing the fœtus. The ſources of nutriment, during fœtal life, are particularly evident in the ovum of birds.

In the hiſtory of incubation it will be found, that the albumen begins to diminiſh as ſoon as the fœtus becomes apparent, that it continues to decreaſe regularly as the chick grows, and that this fluid is entirely conſumed at the end of incubation: there is, therefore, no doubt that the white of the egg is the ſubſtance from which the chick is formed. It has been ſuppoſed by ſome writers, that the yolk alſo contributes to the ſupport of the chick while in the egg. This opinion reſts chiefly upon the circumſtance of the yolk becoming larger and more fluid after the white begins to diminiſh, which has been attributed to the albumen paſſing into it, that the two fluids might be mixed together, and afterwards converted into the ſubſtance of the chick. Maitre Jan, Leveille, and others believed, that the white is abſorbed by the chalazæ, and thus conveyed into the yolk-bag, and Leveille has even pretended to demonſtrate the tubular ſtructure of one of the chalazæ. We have already ſtated, that by the ſtricteſt examination we could not perceive the ſtructure deſcribed by Leveille; we are therefore led to conclude, that the fluidity of the yolk, during incubation, is occaſioned by the organization of that humour undergoing a change from the application of heat. We have found alſo the yolk become fluid when eggs were ſat upon, which had not been fecundated by the cock, and in which the white was not ſenſibly diminiſhed. The weight of the yolk at the end of incubation, almoſt proves that it is not concerned in the nouriſhment of the chick, until after the animal is excluded from the egg.

We confeſs, however, that we are unable to form a decided opinion with reſpect to the manner in which the albumen is carried into the body of the chick. Throughout incubation the white tends to the lower and ſmall end of the egg; the chick is placed at the upper and great end. There is, therefore, no direct communication between the chick and the albumen. The blood-veſſels of the egg have apparently no immediate connection with the white, until its proper membrane is formed, at which time this humour is already much reduced, and even then there are only a few wandering veſſels ſpread over its membrane. Theſe facts afford reaſon for the ſuppoſition that the white paſſes into the yolk-bag, through the chalazæ; but, on the other hand, it is ſcarcely credible that the white, after being mixed with the yolk, ſhould alone be abſorbed during incubation, and the latter fluid left undiminiſhed.

The chalazæ, whether they perform the office of abſorbents or not, act as ligaments to the yolk-bag, and have the effect of keeping, throughout incubation, that ſurface of the bag uppermoſt on which the chick is ſituated, in order that it may receive heat from the hen. See EGG.

The uſe of the veſicula umbilicalis is a ſubject on which no ſatiſfactory theory has been yet made out.

The older anatomiſts ſuppoſed this part to be a reſervoir of urine, and gave it the name of *allantois*. Lobſtein conſiders the fluid of the veſicula and the allantois as the nutriment of the fœtus during the firſt periods of its exiſtence. Soemmerring and Blumenbach ſuppoſe that the veſicula umbilicalis is intended for the nouriſhment of the fœtus in the human ſubject. Although it does not appear that this uſe of the veſicula or allantois has been in any degree proved, the arguments employed are concluſive againſt it being a reſervoir for urine, and particularly ſo with reſpect to birds and the human ſubject.

The veſicula umbilicalis attains a conſiderable ſize, and is filled with its proper fluid before the kidnies exiſt; and although the membrane continues to increaſe, the quantity of the fluid it contains by no means keeps pace with the growth of the kidnies. We cannot admit the reaſoning of Haller, who concludes that the exiſtence of fluid in the allantois is a proof that the kidnies ſecrete urine before they are viſible. It has not yet been aſcertained that the fluid contained in the allantois is urine even in quadrupeds, where this bag communicates ſo plainly with the bladder. Lobſtein found, after the allantois had acquired a very conſiderable bulk, that the kidnies were ſmall and pale, and reſembled organs which had not yet been called into action. The bladder alſo was contracted. He very judiciouſly remarks, that if the allantois were diſtended to the ſize that it is known to poſſeſs in the early periods of geſtation and incubation by the ſecretion of the kidnies, it would become before birth a moſt prodigious ſac. It is extremely improbable that the ſecretion of urine ſhould diminiſh or be ſuſpended after the kidnies were perfectly formed, by which ſuppoſition alone the ſmaller relative ſize of the allantois in the latter periods of fœtal life could be explained

We may further obſerve, that there is no reſervoir provided for any of the other ſecretions of the fœtus, and that even the gall-bag is not remarkably diſtended, although it evidently contains bile ſome time before birth, and notwithſtanding the liver is the largeſt gland in the body.

In deſcribing the progreſs of incubation, we have mentioned, that the veſicula umbilicalis of birds contributes to the formation of the membrane called the chorion; that its fluid diſappears, leaving behind it ſome layers of a ſoft calcareous ſubſtance, reſembling the excrement of birds, or rather the ſolid parts of the urine of thoſe animals. This excrementitious matter has been conſidered a proof of the veſicula being the receptacle of the urine, but it ſhould be obſerved that the ſame ſort of ſubſtance is found after the conſumption of all the fluids of the egg.

The functions of the veſicula umbilicalis in birds, if there be any peculiar to it, are loſt in thoſe of the chorion.

By recurring to the hiſtory of incubation, it will be found that the external membrane of the yolk-bag, on which the vaſcular area is ſpread, and the chorion, receive a vaſtly larger quantity of blood than circulates at any one moment in the body of the chick. The chorion is not originally a vaſcular membrane; its veſſels ariſe with the veſicula umbilicalis, by which they are conducted from the body of the fœtus. The vaſcularity of the chorion in ſome degree ſucceeds that of the vaſcular area; it appertains chiefly to the arterial ſyſtem, whilſt that of the area is almoſt entirely produced by veins.

The uſe moſt commonly aſcribed to theſe two great ſyſtems of extraneous veſſels, is the oxydation of the blood of the fœtus, for which purpoſe it is alſo believed that the air is admitted into the great end of the egg. We have, however, been led to entertain a different opinion of the offices of the vaſcular area, chorion, and air-cell, in conſequence of ſome experiments we have made, which we ſhall lay before the reader.

Experiment 1.—Two eggs of a *hen* were opened at the great end by deſtroying the ſhell and outer layer of the membrane compoſing the air-cell. The blood-veſſels were ſeen through the membrane of a deep purple colour. Being expoſed to the atmoſpheric air, they became, in a few minutes, a vivid ſcarlet. The ſame eggs were then placed in a jar filled with fixed air, and their blood very ſoon reaſſumed its original purple colour; and upon the eggs being again brought into the common air, the ſcarlet colour of the blood was ſpeedily revived. One of theſe eggs had its blood rendered venous and the other arterial, in the manner above-mentioned. Both were then placed in a veſſel of water, in which they remained all night, and on the next morning each continued to preſerve its proper colour.

Ex. 2.—We took an egg which had been ſat upon 18 days, and having removed a ſquare portion of the ſhell and membrane forming the air-cell, about a quarter of an inch in ſize, it was placed in a jar of carbonic acid gas, over a bath of quickſilver, which was kept throughout the experiment, as nearly as poſſible, at the temperature of 104° Fahrenheit. The motions of the chick cauſe an egg to roll upon a ſmooth ſurface, but in this inſtance no motion was perceived. After the egg had remained an hour in the fixed air it was taken out, and the aperture of the ſhell was carefully cloſed with paper and glue, and two hours elapſed before the egg began to roll upon the ſurface of the mercury. Upon this occaſion, therefore, the chick appeared to have been ſubmitted three hours to the influence of carbonic acid gas without being deſtroyed.

Ex. 3.—An egg, at the 18th day of incubation, was deprived of the greateſt part of the ſhell, and of the membrane that lines the ſhell; ſo that the veſſels of the chorion were fully expoſed. The membrane of the chorion was moiſtened to increaſe the effect. The egg was ſuffered to remain for 25 minutes in the fixed air, during which time the chick ſhewed no motion; but upon being removed into atmoſpheric air it ſtruggled as uſual.

Ex. 4.—The air contained in the cells, during the latter ſtages of incubation, was collected from a number of eggs, and ſubjected to experiment in a graduated glaſs tube. It afforded, as nearly as may be, the ſame products that are obtained from atmoſpheric air, after it has been ſpoiled by reſpiration; from which it would appear, that it was the preſence of undiluted fixed air in the 2d and 3d experiments that cauſed the motions of the chick to ceaſe, and not the abſence of oxygen gas.

Ex. 5.—Being aware of the fatal effects upon the chick, which have been reported to follow covering the ſhell of the egg, ſo as to ſtop the further admiſſion of air into it, we varniſhed the ſurface of ſeveral eggs at different periods of incubation. The reſult of this experiment was nearly the ſame in every inſtance. The chick always died; not, however, immediately, but in two, three, or four days, and apparently not in conſequence of being unſupplied with freſh air, but from being unprovided with any kind of air to occupy the ſpace cauſed by the expenditure of the fluid contents of the egg in the formation of the chick: for, in theſe caſes, we found the yolk more or leſs diſorganized, the membranes ſometimes ruptured, and the fœtus always malformed or imperfectly developed. If the death of the chick had been occaſioned by the deprivation of oxygen, it would have been immediate, and unattended with any change in the ſtructure of the fœtus.

The gradual admiſſion of air into the eggs of birds takes place as a matter of neceſſity, becauſe the ſhell, being hard and unyielding, cannot accommodate its form to the bulk of its contents in proportion as they diminiſh; for the parts originally contained in the egg occupy a much larger ſpace, as already mentioned, than when the chick is fully formed.

The preceding experiments prove that the air does not paſs into the egg for the purpoſe of effecting any change in the blood of the fœtal chick, ſimilar to the proceſs of reſpiration, as has been generally ſuppoſed. It is true, nevertheleſs, that when the blood is firſt expoſed to the air contained in the great end of the egg, it becomes oxydated by it ; and hence, during the firſt days of incubation, all the blood-veſſels of the vaſcular area are obſerved to be of an arterial colour : but as there are no means of expelling the air as it becomes ſpoiled, and as the ſupply of pure air afterwards is too ſmall in quantity to produce any effect upon the blood, all the veſſels are of the purple or venous colour in the latter periods of incubation. This appearance of the blood has been obſerved to exiſt by many writers upon incubation, and coincides with the experiments we have related above.

It may be aſked, what end is anſwered by the diſtribution of ſo much blood to the membranes of the egg, if it be not for its expoſure to oxygen gas? This is a queſtion which, perhaps, cannot be ſolved by direct experiments.

We conceive, however, that it is neceſſary, during fœtal life, to have a greater quantity of blood formed than is employed in the organs of the young animal. The functions of the blood-veſſels of the fœtus are almoſt confined to the creation of its body ; but in the adult animal the principal part of the maſs of blood is conſumed in furniſhing the various ſecretions. The vaſcular membranes of the ovum may be conſidered as performing the office of the various ſecretory organs, the actions of which are dormant, at leaſt during the early periods of fœtal life. By this means alſo the organs of the body are accuſtomed to the preparation and preſence of a quantity of blood which is wanted immediately after the young animal leaves the uterus or the egg : indeed, without ſuch a proviſion, it would ſeem to be impoſſible for the fœtus to aſſume, in a moment, the functions of an independent ſtate of exiſtence.

Further, the extraneous circulation on the membranes appears to be the means by which the nutritive fluids of the egg are converted into blood. This is almoſt demonſtrated in the vaſcular area, in which the red blood appears before its veſſels have any viſible connection with the body of the chick.

The *membrane* containing the vaſcular area, therefore, we deem the organ of nutriment and aſſimilation. It correſponds to the different viſcera which convert the food into blood in the full-grown or perfect animal. The *chorion* of birds ſupplies the place of the viſcera, which return the particles of the adult body to the common ſtock of nature. We could draw many arguments in ſupport of this theory from the anatomy of the lower claſſes of animals, and from the ſtructure of the vaſcular ſyſtem in particular animals of a higher rank ; but it does not ſeem conſiſtent, with the nature of the preſent article, to enter into an extenſive phyſiological diſcuſſion.

If it be admitted that the blood of the fœtus does not receive that effect from the air which gives the arterial character, it becomes deſirable to aſcertain the power of the fœtus for generating animal heat. With this view we have inſtituted the following experiments.

Ex. 1.—An egg, on which the hen had ſat 17 days, was placed upon a bath of mercury heated to 104° of Fahrenheit, and kept at that temperature for ſeveral hours. The heat of the room was 75°. The upper ſurface of the membranes, when the ſhell was broken to admit the thermometer, raiſed the inſtrument to 92°. The interior of the egg was 95°, and on the inſtrument being thruſt down ſo as to touch that part of the ſhell in contact with the mercury, it did not riſe higher than 100°. From this experiment, the ſtandard heat of the chick appeared to be about 95°.

Ex. 2.—An egg, at the ſame period of incubation as the laſt, had the ſhell entirely removed, and was placed upon a mercurial bath at the heat of 83°, the air of the apartment being 75°. The centre of the egg preſerved the inſtrument at 88°, and when puſhed down upon the membranes next the mercury, it did not fall below 85°.

Ex. 3.—A chick, about 18 days old, was removed from the egg and its membranes, and expoſed for ſome time upon the ſurface of a bath of quickſilver at the temperature of 79°, and becoming gradually cooler as the heat of the ſurrounding air was 75°. The thermometer was introduced into the thorax of the chick, and ſtood at 80° for a ſhort time, even after the chick had died.

The heat of the different parts of the incubated egg cannot be expected to correſpond with each other as long as external heat or cold is applied to one ſurface only, but the three laſt-mentioned experiments, notwithſtanding, appear to us concluſive, with reſpect to the fœtal chick poſſeſſing an independent temperature, and being capable of reſiſting, to a certain extent, both foreign heat and cold.

It is proper to obſerve, that we have made ſome experiments with reſpect to the oxydation of the blood, and the animal heat of the fœtus in mammalia, which entirely correſpond in their reſults with thoſe above related ; and, therefore, fortify our opinion with regard to the abſence of any proceſs analogous to reſpiration during fœtal exiſtence, and likewiſe prove that the young animal has an independent temperature.

We have already mentioned that the yolk loſes very little, if any, of its original weight during incubation ; but that after the chick is excluded from the ſhell it is ſpeedily conſumed. This humour, therefore, is obviouſly deſigned for a proviſional nutriment to ſuſtain the chick until it is able to procure a ſufficient quantity of its natural food. This diſpoſition of the yolk is particularly neceſſary to thoſe birds that live in a wild ſtate, but is uſeful to all.

Anatomiſts are divided with reſpect to the manner in which the yolk is conveyed into the ſyſtem of the chick. Some aſſert that it paſſes into the alimentary canal, through the ductus vitello inteſtinalis, where it is digeſted previous to its being abſorbed by the lacteals. Others deny that it is to be found in the ſtomach or inteſtines, and believe that it is abſorbed immediately from the yolk-bag. We are diſpoſed to adopt the latter opinion, both from never having being able to diſcover any yolk in the inteſtinal canal, and from a number of reaſons, which indirectly go to diſprove the paſſage of the yolk through the ductus vitello inteſtinalis.

In the firſt place, there does not ſeem to be any power by which the yolk can be tranſmitted into the inteſtine. The yolk-bag itſelf has no muſcular coat, and the mere preſſure of the parietes of the abdomen of the chick, even if ſufficiently ſtrong, would be exerted as much upon the inteſtines as the yolk-bag, and might therefore as readily urge the contents of the former into the latter, as the yolk into the gut ; for the ductus vitello inteſtinalis does not penetrate the coats of the inteſtine obliquely, ſo as to produce the effect of a valve, but has merely a ſlight contraction at the orifice, which muſt operate equally on both ſides.

There would appear to be no neceſſity for the yolk to paſs into the alimentary canal, or to be ſubjected to any proceſs of digeſtion or aſſimilation previous to its entering the ſyſtem of the chick. It is already a vital fluid, which is proved by Mr. Hunter's experiments upon the temperature of eggs. (See Egg.) If the humours of the egg did not poſſeſs vital properties, they would very ſoon become putrid from the heat of incubation.

When we contemplate the ſtructure of the yolk-bag, it muſt be perceived to be not only continuous with the inteſtinal canal, but to reſemble the latter in organization, except that the muſcular coat is wanting. The external membrane of the bag differs in no reſpect from the peritoneal coat of the inteſtines; and the internal membrane is ſo analogous to the villous coat, that we cannot heſitate to allow them the ſame functions. No advantage, therefore, would be gained by the paſſage of the yolk into the inteſtine.

The abſorption of this humour, by the valvular or internal membrane of the yolk-bag, ſeems proved by the organization of the yolk undergoing a change upon the ſurface which is in contact with the membrane, while the central part is unaltered. The circumſtance alſo, of a concrete ſubſtance, reſembling the reſidue of the albumen, being left in the yolk-bag after the nutritious parts of the yolk are conſumed, affords a ſtrong evidence that the latter are removed by a proceſs of abſorption; for if the yolk paſſed through the ductus vitello inteſtinalis, it would diſappear without diſtinction of parts.

The authors who believe that the yolk is carried into the ſyſtem without a previous preparation in the alimentary canal, attribute the office of abſorption to the red veins. In proof of this opinion Blumenbach and others ſtate that they have detected upon ſome occaſions a yellow fluid in the veins of the bag, which they have ſuppoſed to be the yolk in its paſſage. Notwithſtanding this appearance, which we have ſometimes alſo ſeen, it appears to us moſt probable that the yolk is abſorbed by the ſame ſyſtem of veſſels which take up the chyle from the ſmall inteſtines. The yolk-bag and inteſtinal canal, as already mentioned, are continuous parts, and ſimilarly organized. The yolk-bag is, in fact, a proceſs of the inteſtines, and ſhould be conſidered as a portion of the body of the chick. It is ſupplied by the ſame blood-veſſels as the inteſtines; why ſhould we therefore deny it the lacteal veſſels?

Another argument againſt the abſorbing function of the veins of the yolk-bag may be deduced from the ſize of theſe veſſels at different periods. During the early part of incubation they are large and numerous; but after the yolk-bag paſſes into the abdomen of the chick, where their abſorbing function chiefly, if not entirely, exiſts, if it does at all, they become ſmaller and fewer than the arteries. The veſſels of the yolk-bag, when they conſtitute the vaſcular area, are the organs of ſanguification for the chick. After incubation they appear to become the nutritious veſſels of the bag itſelf.

It may ſeem not eaſy to aſſign a uſe for the ductus vitello inteſtinalis, unleſs we grant it to be for tranſmitting the ſubſtance of the yolk into the alimentary canal. If, however, this ſhould not be the caſe, ſtill a communication would probably exiſt between the yolk-bag and the inteſtine; for it is without example, we believe, for the continuity to be interrupted by two adjoining cavities that have a ſimilar organization. The ductus vitello inteſtinalis we think, therefore, would exiſt as a matter of courſe, independently of any offices it might perform. We have deſcribed the purpoſes this part ſerves in the full grown bird; it is not, therefore, without its uſes.

For the hiſtory of fœtal life in oviparous animals in general, ſee Ovum.

INCUBUS, in *Medicine*, from the Latin *incubare, to lie* or *ſit upon*, the ſame with the Engliſh *night-mare*, ſignifies a ſtate of imperfect ſleep, accompanied with an oppreſſion of the breathing, and frightful dreams.

By the Greeks this affection was deſignated by a name of ſimilar import, ἐφιάλτης, *ephialtes*, from the verb ἐφάλλομαι, *I leap upon*; and it has received various other appellations expreſſive of the ſenſe of weight and oppreſſion of the cheſt, the laborious reſpiration, &c. as well as indicative of the hypotheſes by which its occurrence was explained. Thus it has been called ἐπιβολη, πνιγμὸς, *epilepſia nocturna, aſthma nocturnum*, &c.; and by Pliny, *ludibria fauni*, from the ſame notion which dictated the more modern appellations of *hag-riding, wizard-preſſing, mare-riding*; *dier mahr*, or *das reiten der mahr*, of the Germans; *cochemar* of the French; *night-mare*, &c.

This diſorder ſeizes perſons, while ſleeping, who imagine that they feel an extraordinary compreſſion or weight about the breaſt and ſtomach, which they cannot by any effort ſhake off. In this agony they ſigh, groan, and utter indiſtinct ſounds; ſometimes they cry out, but more frequently they attempt to ſpeak, or to move in vain. Theſe feelings give riſe to various frightful ſuggeſtions of the imagination: the patient fancies himſelf to be ſtruggling with ſtrong men or devils, or to be in a houſe on fire, or in danger of being drowned in the ſea or ſome river; and in attempting to run away from danger, or climb up a hill, he fancies he falls back as much after every ſtep as he had advanced before. At length the ſenſations of oppreſſion become intolerable, and the patient awakes; but the terror excited by the frightful ideas attending the night-mare, leaves often a palpitation of the heart, with great anxiety and languor, and ſometimes a tingling of the ears, and a tremor over the whole body.

It is altogether unneceſſary to attempt an enumeration of the numerous hypothetical explanations which have been attempted to be given of the phenomenon of *incubus*, and which have been detailed by Awen, Bond, and other writers. (See Awen, Poſit. inaugur. de Incubo. Argentorat. 1676. Bond, Eſſay on the Incubus or Night-mare, 1753.) The diſorder has commonly been ſuppoſed to proceed from a ſtagnation of the blood in the ſinuſes of the brain, or in the veſſels of the lungs, or from too great a quantity of blood being ſent to the head. The horizontal poſture, in time of ſleep, and the preſſure of the ſtomach upon the *aorta*, in a ſupine ſituation, have been thought ſufficient to occaſion a more than uſual diſtention of the *ſinuſes* and other veſſels of the brain; and the weight of the heart, preſſing on the left auricle and large trunks of the pulmonary veins, may, it is ſuppoſed, prevent the eaſy return of the blood from the lungs, and thus produce an oppreſſion and ſenſe of weight and ſuffocation in the breaſt. (See Bond, chap. ii.) But without entering into a particular examination of theſe opinions, which are far from being ſatisfactory, we may obſerve, with Dr. Whytt, that, if they were true, ſome degree of the night-mare ought to happen to every body that lies upon his back, eſpecially after eating a full meal. Further, if a horizontal ſituation could overcharge the brain with blood, ſo as to occaſion the *incubus*, how comes it that people, who remain for ſome time in an inverted poſture, do not feel this diſeaſe beginning to attack them? And why does a ſlighter degree of the night-mare ſometimes ſeize people who ſleep in an erect ſituation in a chair? a circumſtance which ſometimes occurs, not only after eating, but when the ſtomach is out of order, and troubled with wind. As the weight of the ſtomach, even when filled with food, can have ſcarcely any effect upon the motion of the blood in the *aorta*, ſo the preſſure of the heart is by much too ſmall to be able ſenſibly to retard the motion of that fluid in the pulmonary veins, otherwiſe, people exhauſted by tedious diſeaſes, who generally lie on their back, would be conſtantly affected with the *incubus*.

We know that certain medicines or poiſons, worms, and even corrupted bile, or other humours, by diſagreeably affecting the nerves of the ſtomach, produce an oppreſſion about the breaſt, wild imaginations, frightful dreams, raving, and inſenſibility; and there is no doubt that low ſpirits, melancholy, and diſturbed ſleep, often proceed from a diſordered ſtate of the ſtomach. It ſeems, therefore, more probable that the ſeat of the night-mare is principally in that organ. It is well aſcertained that ſome forms of epilepſy, and of hyſterical fits, originate from diſorder in that *viſcus*; and Galen conſidered the *incubus* as a nocturnal or ſlighter epilepſy. People troubled with nervous and hypochondriac affections, and who have delicate or flatulent ſtomachs, are more peculiarly ſubject to this diſorder; and it is obſerved, that a heavy or flatulent ſupper greatly aggravates the night-mare, in thoſe who are prediſpoſed to it. The ſympathy of the ſtomach with the head, heart, lungs, and diaphragm, is ſo remarkable, that there can be no difficulty in referring the ſeveral ſymptoms of the *incubus* to a diſagreeable irritation of the nerves of the ſtomach.

The *incubus* is moſt apt to ſeize perſons when lying on their back, becauſe, in this poſition, on account of the ſtomach and other abdominal viſcera preſſing more upon the diaphragm, we cannot inſpire with the ſame eaſe as when we ſit up or lie on one ſide. Further, in that ſituation of the body the food ſeems to lie heavier on the ſtomach, and wind in it does not ſeparate ſo readily by the *æſophagus* and *pylorus*, as in an erect poſture, when theſe orifices are higher than the other parts of the ſtomach. The night-mare only occurs in the time of ſleep, becauſe the ſtrange ideas excited in the mind, in conſequence of the diſordered feelings of the ſtomach, are not then corrected by the external ſenſes as they are when we are awake; nor do we, by an increaſed reſpiration or other motions of the body, endeavour to ſhake off any beginning uneaſy ſenſation about the ſtomach or breaſt. The *incubus* generally occurs in the firſt ſleep, and ſeldom towards morning, becauſe at the earlier period the ſtomach is more loaded with food, and that in a more crude and indigeſted ſtate than in the morning. A leſſer degree, amounting only to frightful dreams, is almoſt a conſtant concomitant of overloaded ſtomach in ſome habits. See DREAM.

In fact, if the night-mare were owing to a ſtagnation of the blood in the lungs from the weight of the heart, or in the ſinuſes and other veſſels of the brain from the horizontal poſture of the body, it would become greater the longer it continued, and would ſcarcely ever go off ſpontaneouſly. But we know that this diſeaſe, after affecting people for ſome time, often gradually ceaſes, and is ſucceeded by refreſhing ſleep: for as ſoon as the load of meat, or wind, or other cauſe diſagreeably affecting the nerves of the ſtomach is removed, the oppreſſion and weight on the breaſt, wild imaginations, frightful dreams, &c. vaniſh; as all theſe proceed originally from the diſorder of the ſtomach. It may be remarked, however, that, as neither flatulency, phlegm, nor crudities in the ſtomach, ever produce the ſymptoms of *hypochondriaſis*, unleſs the nerves of that organ be indiſpoſed; ſo neither a horizontal poſture, ſleep, nor heavy ſuppers, ever produce the night-mare, at leaſt in any conſiderable degree, unleſs the perſon be already prediſpoſed to the complaint, from the particular condition of the nerves of the ſtomach.

But although the ſtomach is the part commonly affected primarily in the caſe of *incubus*; yet ſymptoms like thoſe of the night-mare may ſometimes ariſe without any fault of the ſtomach, when the lungs, or even the brain, are affected. Thus Dr. Whytt obſerves, that aſthmatic patients, whoſe lungs are much obſtructed, are ſometimes diſturbed, in time of ſleep, with diſtreſſing dreams, and oppreſſed with a ſenſe of ſuffocation. Startings and oppreſſions about the præcordia, with painful dreams, are indeed common occurrences from *hydrothorax*, chronic coughs, and other pulmonary obſtructions; but they are not ſtrictly analogous to the common night-mare. Dr. Lower mentions a patient, who, though he could ſleep pretty eaſily with his head inclined forward; yet, in the oppoſite ſituation, he was always ſoon awaked with horrid dreams and tremors; the cauſe of which appeared, after his death, to have been a great quantity of water in the ventricles of the brain. At all events, a plethoric ſtate of habit, by rendering the circulation through the lungs leſs free, may help to produce, or at leaſt increaſe, the oppreſſion of the breaſt in the night-mare.

The Cure.—As incubus, then, is only a ſymptom of diſordered or loaded ſtomach, and ariſes out of the irritation and morbid feelings which are thus produced during ſleep, the relief of the diſeaſe, generally ſpeaking, lies within a narrow compaſs. *Temperance* in eating and drinking, eſpecially at late hours; taking, in fact, either extremely light ſuppers or none at all; and when the dinner is ſo late as to be only a ſupper with another name, being cautious that that alſo ſhould be moderate in quantity, and eaſily digeſtible and unſtimulating in its nature; drinking thin, ſub-acid liquors, where theſe are agreeable to the conſtitution,—theſe are the principal remedies required. Briſk active exerciſe, by which the digeſtive powers may be aided and the ſtomach ſtrengthened, is alſo adviſable. It were uſeful, too, to ſleep with high pillows, and to lie on the ſide as much as poſſible, in preference to the back. If the functions of the ſtomach are much diſordered with flatulency, heart-burn, acidity, or oppreſſion, with pain, or nauſea, after taking food, the remedies recommended for *indigeſtion* (which ſee) muſt be reſorted to. The bowels ſhould be kept open. See Whytt on Nervous Diſorders, chap. vi. § 18.

INCUMBENT, in *Law*, a clerk reſident on his benefice, with cure.

He is called incumbent of ſuch church, becauſe he ought to bend his whole ſtudy to diſcharge his cure. See RECTOR and VICAR.

INCUMBRAVIT. See QUARE *incumbravit*.

INCURABILI, the name of one of the celebrated conſervatorios or muſic-ſchools at Venice, where orphan girls, or girls of worthy parents in indigence, uſed to be well educated and regularly bred to muſic as a profeſſion. Galuppi was maſter of this conſervatorio in 1770, when the compoſition and performance were exquiſite.

INCURVATION, the act of bending a bone, or other body, from its natural ſhape.

INCURVATION *of the Rays of Light*. See LIGHT, and REFRACTION.

INCUS, in *Anatomy*, one of the ſmall bones contained in the cavity of the tympanum. See EAR.

INCUSSU, in *Geography*, a town of Africa, in the kingdom of Congo; 80 miles S. of St. Salvador.

INDAL, a town of Sweden, in the province of Medelpad;

pad, on a river of the ſame name. N. lat. 62° 34′. E. long. 16° 23′.

INDEA, a town of Africa, in the kingdom of Yemina, on a river of the ſame name.

INDEBITATUS Assumpsit, in *Law*. See Assumpsit.

INDECIMABLE, Indecimabilis, is applied to things not tithable, or which by law ought not to pay tythe.

INDEFEASIBLE, or Indefeazable, ſignifies what cannot be defeated, or made void. As, a good and indefeaſible eſtate. No one, who conſiders our laws, conſtitution, and hiſtory, without prejudice, and with any degree of attention, will aſſert, that the doctrine of hereditary right implies an indefeaſible right to the Engliſh throne. See *Right of* Crown.

INDEFINITE, Indeterminate, that which has no certain bounds, or to which the human mind cannot affix any. Des Cartes uſes the word, in his philoſophy, inſtead of infinite, both in numbers and quantities, to ſignify an inconceivable number, or number ſo great, that an unit cannot be added to it; and a quantity ſo great, as not to be capable of any addition.

Thus, he ſays, the ſtars, viſible and inviſible, are in number indefinite; and not, as the ancients held, infinite; and that quantity may be divided into an indefinite number of parts, not an infinite number.

Indefinite is alſo uſed, in the *Schools*, to ſignify a thing that has but one extreme: for inſtance, a line drawn from any point, and extended infinitely.

Thus, what they call *eternity a parte ante*, or *eternity a parte poſt*, are indefinite durations.

Indefinite, in *Grammar*, is underſtood of nouns, pronouns, verbs, participles, articles, &c. which are left in an uncertain indeterminate ſenſe, and not fixed to any particular time, thing, or other circumſtance.

Indefinite *Propoſition*, in *Logic*. See Proposition.

INDELAVOY, Endelavoy, or *Indelvai*, in *Geography*, a town of Hindooſtan, in Golconda, lying in the route between the Godavery and Hydrabad; 75 miles N. of Hydrabad. N. lat. 18° 26′. E. long. 78° 40′.

INDELIBLE, formed from *delere, to blot*, with the prepoſition *in*, taken negatively, that which cannot be blotted out, or effaced.

Thus baptiſm, and the order of the prieſthood, are ſaid to convey indelible characters.

INDEMNITY, formed from the negative *in*, and *damnum*, *loſs*, in *Law*, an act by which one promiſes to guarantee, or ſave harmleſs ſome other perſon from any loſs or damage that might accrue to him on any particular account.

When a church is appropriated to an abbey, or college, the archdeacon loſeth his induction money for ever; in recompence whereof he ſhall have yearly, out of the church ſo appropriate, one or two ſhillings, more or leſs, for a penſion, as was agreed at the time of the impropriation; and this penſion is called an indemnity.

Indemnity, with regard to eſtates. See Warranty.

Indemnity. See *Act of* Grace.

INDEN, in *Geography*, a town of Switzerland, in the Valais; 18 miles E. of Sion.

INDEN-HOTUN, a town of Chineſe Tartary, the capital of the Mantchew Tartars, where they began to eſtabliſh their empire over China. N. lat. 41° 46′. E. long. 124° 36′.

INDENTATIONS *of the Coaſt of the Ocean*, in *Geology*, or the peninſulas, headlands, points, bays, gulfs, eſtuaries, &c. which occur on the ſhores of moſt iſlands and continents, are phenomena worthy the attentive conſideration of geological obſervers. M. de Luc, in his Geological Travels, vol. i. p. 333 and 336, has conſidered many of the circumſtances attending the headlands and gulfs of the northern coaſt of Europe, and very properly repreſents, that they ariſe from the ſyſtem of vallies and hills, which are ſeen inland, continuing down much below the preſent level of ſea, even to the greateſt fathomable depths in ſome inſtances: and Mr. Farey, who has remarked on this part of M. de Luc's work in the Philoſophical Magazine (vol. xxxvi. p. 7.), obſerves, that the hills all evidently ran out in headlands into the ſea, juſt as they would into a ſea at a level conſiderably above the preſent, of which a perfect idea may be obtained by tracing an extended *level* line in any country; and that the operations of the tides and waves have a powerful tendency, in moſt inſtances, to leſſen the indentations of the coaſts, by waſhing away the projecting points of hills, and throwing up the alluvial matters therefrom in the intervening gulfs, where marſhes are accumulated; and that the coaſts, where cliffs or precipices occur at the headlands only, have not originated, in moſt inſtances, from faults or depreſſions of the ſtrata under the ſea beach, but are occaſioned by the falling and waſhing away of the points of the hills. It is evident, that where rocky cliffs fringe the borders of the gulfs, as well as the headlands of a diſtrict, ſuch cliffs have a different origin from thoſe which are confined to the headlands. See Encroachment *of the Sea*.

INDENTED, Indentee, in *Heraldry*, is when the outline of a bordure, ordinary, &c. is notched, in form of the teeth of a ſaw.

Indented *Leaf*. See *Serrated* Leaf.

Indented *Line*, in *Fortification*. See Redens.

Indented *Medals and Wheel*. See Medals and Wheel.

INDENTURE, in *Law*, a writing which compriſes ſome contract between two, at leaſt; being indented at top anſwerable to another part, which has the ſame contents. See Deed.

INDEPENDENT *Company and Troop*. See Company and Troop.

INDEPENDENTS, in *Eccleſiaſtical Hiſtory*, a ſect of Proteſtants in England and Holland: ſo called, as denying not only any ſubordination among their clergy, but alſo all dependency on any other aſſembly.

They maintain, that every ſeparate church, or particular congregation, has in itſelf radically and eſſentially every thing neceſſary for its own government; that it has all eccleſiaſtical power and juriſdiction; and is not at all ſubject to other churches, or their deputies, nor to their aſſemblies, or ſynods.

Robinſon, the founder of the ſect, makes expreſs uſe of this term in explaining his doctrine relating to eccleſiaſtical government: "Cætum quemlibet particularem," (ſays he, in his Apologia, cap. 5. p. 22.) "eſſe totam, integram et perfectam eccleſiam ex ſuis partibus conſtantem, immediate et independenter (quoad alias eccleſias) ſub ipſo Chriſto." It may probably have been from this very paſſage that the title of independents was originally derived. The diſciples of Robinſon, originally called *Browniſts* (which ſee), becauſe John Robinſon, the founder of this ſect, was paſtor of a congregation of Browniſts that had ſettled at Leyden, did not reject the appellation of Independents. It was certainly utterly unknown in England before the year 1640: at leaſt it is not once mentioned in the eccleſiaſtical canons and conſtitutions that were drawn up during that year, in the ſynods or viſitations held by the archbiſhops of Canterbury, York, and other prelates, in which canons all the various ſects that then ſubſiſted in England are particularly mentioned. See Wilkins's Concilia Magnæ Britanniæ et Hiberniæ, vol. iv. cap. 5. p. 548.

It is true, that not long after this period, and more particularly from the year 1642, we find this denomination very frequently in the Engliſh annals. The Engliſh Independents were ſo far from being diſpleaſed with it, that they aſſumed it publicly in a piece, which they publiſhed in their own defence at London, in the year 1644, entitled "Apologetical Narration of the Independents." But in proceſs of time, in order to avoid the odium of ſedition and anarchy charged on this ſect, the true and genuine Independents renounced this title, and called themſelves "Congregational Brethren;" and their religious aſſemblies "congregational churches." The firſt independent, or congregational church in England, was ſet up in the year 1616, by Mr. Jacob, who had adopted the religious ſentiments of Robinſon. The Independents, though ſprung originally from a congregation of Browniſts, were much more commendable than the latter, both in the moderation of their ſentiments, and the order of their diſcipline. The Browniſts, as we have already mentioned under that article, allowed all ranks and orders of men promiſcuouſly to teach in public, and to perform the other paſtoral functions; whereas the Independents had, and ſtill have, a certain number of miniſters, for the moſt part regularly educated, choſen reſpectively by the congregations where they are fixed; nor is any perſon among them permitted to ſpeak in public, before he has ſubmitted to a proper examination of his capacity and talents, and been approved of by the congregation to which he miniſters. The charge alleged againſt them by our hiſtorian Rapin, (Hiſt. of England, vol. ii. p. 514. fol. ed.) who ſays, that they could not ſo much as endure ordinary miniſters in the church, &c. is, therefore, evidently falſe and groundleſs. He was led into his miſtake by confounding the Independents and Browniſts. There are other charges, no leſs unjuſtifiable, that have been urged againſt the Independents by this celebrated hiſtorian, and others of leſs note. Rapin ſays, that, with regard to the ſtate, they abhorred monarchy, and approved only a republican government. This might have been true with regard to ſeveral perſons among the Independents, in common with thoſe of other ſects; but it does not appear from any of their public writings that republican principles formed the diſtinguiſhing characteriſtic of this ſect. On the contrary, in a public memorial drawn up by them in 1647, they declare, that "they do not diſapprove of any form of civil government, but do freely acknowledge that a kingly government, bounded by juſt and wholeſome laws, is both allowed by God, and alſo a good accommodation unto men." The Independents, however, have been generally diſtinguiſhed by the denomination of regicides, under a notion that they were chargeable with the death of Charles I. Whether this fact be admitted or denied, and this is not a place proper for the inveſtigation of it, no concluſion can be fairly drawn from the greater prevalence of republican principles, or from violent proceedings at that period, that can affect the diſtinguiſhing tenets and conduct of the Independents in general; and eſpecially of the ſect that bears this denomination in our times. It is certain that our Independents are ſteady friends to a limited monarchy. Rapin is farther miſtaken, when he repreſents the religious principles of the Independents as contrary to thoſe of all the reſt of the world. It appears from two confeſſions of faith, one compoſed by Robinſon, on behalf of the Engliſh Independents in Holland, and publiſhed at Leyden in 1619, entitled "Apologia pro Exulibus Anglis, qui Browniſtæ vulgo appellantur," and another drawn up in London in the year 1658, by the principal member of this community in England, entitled "A Declaration of the Faith and Order owned and practiſed by the Congregational Churches in England, agreed upon and conſented unto by their Elders and Meſſengers, in their Meeting at the Savoy, Oct. 12, 1658;" as well as from other writings of the Independents, that they differed from the reſt of the reformed in no ſingle point of any conſequence, except that of eccleſiaſtical government; and their religious doctrines were almoſt entirely the ſame with thoſe that are adopted by the church of Geneva. During the adminiſtration of Cromwell the Independents acquired very conſiderable reputation and influence; and he made uſe of them as a check to the ambition of the Preſbyterians, who aimed at a very high degree of eccleſiaſtical power, and who had ſucceeded, ſoon after the elevation of Cromwell, in obtaining a parliamentary eſtabliſhment of their own church government. But after the reſtoration of Charles II. their cauſe declined; and in the year 1691, under the reign of king William, they entered into an aſſociation with the Preſbyterians reſiding in and about London, under certain heads of agreement, comprized in nine articles, that tended to the maintenance of their reſpective inſtitutions. Theſe may be found in the ſecond volume of Whiſton's Memoirs of his Life and Writings; and the ſubſtance of them in Moſheim, ubi infrà.

At this time the Independents and Preſbyterians, called from this aſſociation the United Brethren, were agreed with regard to doctrines, being generally Calviniſts, and differed only with reſpect to eccleſiaſtical diſcipline. But, at preſent, though the Engliſh Independents and Preſbyterians form two diſtinct parties of Proteſtant diſſenters, they are diſtinguiſhed by very trifling differences with regard to church government; and the denominations are more arbitrarily uſed to comprehend thoſe who differ in theological opinions. The Independents are generally more attached to the tenets diſtinguiſhed by the term orthodoxy or calviniſm, than the Preſbyterians.

Independentiſm is peculiar to Great Britain, the United States of America, where it was carried firſt in 1620, and by ſucceſſive Puritan emigrants in 1629 and 1633, from England, and the United Provinces. One Morel, in the ſixteenth century, endeavoured to introduce it into France; but it was condemned at the ſynod of Rochel, where Beza preſided; and again at the ſynod of Rochel, in 1644.

On the ſubject of this article, ſee Moſheim's Eccl. Hiſt. by Macleane, vol. v. p. 398, &c. 8vo. Neal's Hiſt. of the Puritans, vol. ii. p. 107, &c. vol. iii. p. 547, &c. vol. iv. p. 187, &c. Burnet's Hiſt. of his Own Times, vol. i. p. 46, &c.

INDERGEREE, in *Geography*, a river on the N. E. coaſt of Sumatra, which runs into the ſea. S. lat. 0° 33'. E. long. 103° 20'.

INDERGUR, a town of Hindooſtan, in Guzerat; 15 miles E. of Damaun.

INDERMAY POINT, a cape on the N. coaſt of Java. S. lat. 6° 12'. E. long. 108° 18'.

INDERSKAIA, a town of Ruſſia, on the river Ural; 72 miles N. of Gurev.

INDERSOUL, a town of Hindooſtan, in Baglana; 12 miles E. of Bahbelgong.

INDER-TAUPLITZ, a town of the duchy of Stiria, on the Enns; 14 miles W. of Rottenman.

INDERVA, a ſmall iſland in the Perſian gulf; 50 leagues W. of Ormus.

INDETERMINATE, in *Geometry*, is underſtood of a quantity either of time or place, which has no certain or definite bounds. See INDEFINITE.

INDETERMINATE *Analyſis*, is a particular branch of algebra, in which there is always propoſed a greater number of unknown quantities than there are equations; whence, from what we have ſeen under the article ALGEBRA, the queſtions become unlimited; but in this ſpecies of equations, the ſolutions muſt always be given in integers, or rational fractions; and this condition frequently fixes a limit to the number of anſwers that an equation admits of, and even ſometimes renders the problem impoſſible; though, in the generality of caſes, the number of ſolutions is indefinite. When, amongſt the unknown quantities, there are none that exceed the ſimple power, the equation is ſaid to be of the *firſt degree:* when the ſecond power enters into the equation, it is ſaid to be of the *ſecond degree:* and when the third power or cube enters, it is of the *third degree;* and ſo on.

Every indeterminate equation of the firſt degree, as

$$ax \pm by \pm cz \pm d \pm \text{&c.} = 0$$

is ſolved by means of the more ſimple equation

$$ap - bq = \pm 1.$$

And every indeterminate equation of the ſecond degree has its ſolution, if not abſolutely depending, at leaſt intimately connected with the ſolution of the equation

$$p^2 - Nq^2 = \pm 1.$$

Before, therefore, entering upon the general ſolution of indeterminate problems, it will be proper to conſider more particularly the two equations above-mentioned.

PROP. I.

To find the values of x and y, in the equation

$$ax - by = \pm 1.$$

Firſt, it may be obſerved, that this equation is always poſſible under either condition of the ambiguous ſign $\pm$, provided that a and b be prime to each other; and without this, the equation is always impoſſible; becauſe, in that caſe, the firſt ſide of the equation will be diviſible by the common diviſor of a and b; whereas the ſecond ſide, ± 1, has no diviſor; and, conſequently, no equality can obtain. But when a and b are prime to each other, the ſolution may always be obtained by the following rule: Divide the greateſt of the two given numbers a and b by the other, and then always the laſt diviſor by the laſt remainder, as in the uſual method of finding the greateſt common meaſure of two numbers, and let the ſucceſſive quotients ariſing from this operation be denoted by $\alpha, \beta, \gamma, \delta$, &c. See COMMON *Meaſure.*

With theſe quotients, placed in one horizontal row, make the following calculation; and the terms of the laſt fraction but one will be the values of x and y required; thus

$$\begin{array}{llllll} \text{quot.} & \alpha & \beta & \gamma & \delta & \text{&c.} \\ \text{frac.} & \frac{\alpha}{1}, & \frac{\alpha\beta+1}{\beta}, & \frac{(\alpha\beta+1)\gamma+\alpha}{\gamma\beta+1}, & \frac{[(\alpha\beta+1)\gamma+a]\delta}{(\gamma\beta+1)\delta+\beta} & \text{&c.} \end{array}$$

which may be otherwiſe expreſſed in words: thus, having arranged the ſucceſſive quotients, as above, the firſt fraction will have α for its numerator, and 1 for its denominator; the ſecond will have $\alpha\beta + 1$ for its numerator, and β for its denominator; and all the other numerators will be found by multiplying the numerator of the laſt fraction by the following quotient, and adding thereto the preceding numerator, and the denominators are found exactly in the ſame manner, as is evident in the foregoing fractions. See RATIO.

Ex. 1.—Find the values of x and y, in the equation

$$16x - 41y = 1.$$

```
First  16)41(2
          32
          --
           9)16(1
              9
             --
              7)9(1
                7
               --
                2)7(3
                  6
                 --
                  1)2(2
                    2
                   --
```

$$\begin{array}{llllll} \text{quotients} & 2, & 1, & 1, & 3, & 2 \\ \text{fractions} & \left\{\frac{2}{1},\right. & \frac{3}{1}, & \frac{5}{2}, & \frac{18}{7}, & \frac{41}{16} \end{array}$$

Here the laſt fraction but one is $\frac{18}{7}$, and therefore this gives the values of x and y; that is, $x = 18$ and $y = 7$, which renders $16x - 41y = 1$, as required.

Ex. 2.—Find the values of x and y, in the equation

$$17x - 15y = -1.$$

```
First  15)17(1
          15
          --
           2)15(7
             14
             --
              1)2(2
                2
               --
```

$$\begin{array}{llll} \text{Quotients} & 1, & 7, & 2 \\ \text{Fractions} & \left\{\frac{1}{1},\right. & \frac{8}{7}, & \frac{17}{15} \end{array}$$

Therefore $x = 7$, and $y = 8$, which gives

$$17x - 15y = -1.$$

The demonſtration of this rule belongs properly to continued fractions, which the reader will find very ably treated of, in the Engliſh edition of Euler's Algebra; and in moſt of the French writers on that ſubject, particularly in the "Eſſai ſur la Theorie des Nombres, par Legendre."

Having thus ſhewn the general method of ſolving the indeterminate equation $ax - by = \pm 1$; it only remains to make a few obſervations relating to it, and to ſhew, that one ſolution being obtained, an infinite number of other ſolutions may be deduced from the one known caſe.

In the above examples we found $ax - by = +1$, and $ax - by = -1$, as the queſtions required; but we are frequently led to the ſolution $ax - by = +1$, when the queſtion requires -1, and the contrary; which ſeems at firſt to deſtroy the generality of the rule; but this difficulty is eaſily ſurmounted from the following conſiderations.

Let $ap - bq = +1$, the values of p and q being known, to find, from this equation, the value of x and y, in the equation $ax - by = -1$.

Since $ap - bq = 1$, we have only to make $x = bm - p$, and $y = am - q$, and it is obvious that this ſubſtitution will give

$$a\,(bm - p) - b\,(am - q) = -1;$$

and here, by means of the indeterminate m an indefinite number of values of x and y may be determined.

If from one known caſe, as $ap - bq = +1$, the general values of x and y in the ſame equation $ax - by = +1$ were required; we ſhould only have to make $x = mb + p$, and $y = ma + q$, and we ſhould have ſtill

$$a\,(mb + p) - b\,(ma + q) = ap - bq = +1,$$

where, by means of the indeterminate m, an indefinite number of values of x and y may be obtained. We will now illuſtrate what has been taught by an example, and then proceed to the more general equations; each of which, however, will be found to depend upon the one we have been conſidering.

Ex. 3.—Find the general values of x and y, in the equation

$$13x - 19y = 1.$$

13)19(1
13
—
6)13(2
12
—
1)6(6
6
—

$$\text{Quotients} \qquad 1,\quad 2,\quad 6$$

$$\text{Fractions} \quad \left\{ \frac{1}{1},\ \frac{3}{2},\ \frac{19}{13} \right.$$

we have therefore $p = 3$, and $q = 2$; and this gives

$$13p - 19q = 1.$$

Therefore the general values of x and y are

$$x = 19m + p, \text{ and } y = 13m + q, \text{ or}$$
$$x = 19m + 3, \text{ and } y = 13m + 2.$$

Aſſuming therefore $m = 0, 1, 2, 3, 4$, &c.; we have the following values of x and y,

$$\begin{array}{lccccccc} m = & 0, & 1, & 2, & 3, & 4, & 5 & \&c. \\ x = & 3, & 22, & 41, & 60, & 79, & 98 & \&c. \\ y = & 2, & 15, & 28, & 41, & 54, & 67 & \&c. \end{array}$$

which ſeries may be continued at pleaſure.

If the propoſed equation had been $13x - 19y = -1$, then having found $p = 3$, and $q = 2$, as above; we muſt have made

$$x = 19m - 3; \text{ and } y = 13m - 2;$$

and then, by aſſuming m as before, we ſhould have

$$\begin{array}{lccccccc} m = & 0, & 1, & 2, & 3, & 4, & 5 & \&c. \\ x = & -3, & 16, & 35, & 54, & 73, & 92 & \&c. \\ y = & -2, & 11, & 24, & 37, & 50, & 63 & \&c. \end{array}$$

where it may be obſerved, that the ſucceſſive values of x and y, in both caſes, form a ſeries of arithmeticals, and may therefore be continued with great facility.

PROP. II.

To find the general values of x and y, in the equation

$$ax - by = \pm c.$$

In the firſt place we muſt have either a and b prime to each other, or if they have a common meaſure, c muſt have the ſame, for otherwiſe the equation will be impoſſible; and in this latter caſe, the whole equation may be divided by that common meaſure, and thus reduced to one in which a and b are prime to each other: it will, therefore, only be neceſſary to conſider the quantities a and b as prime to each other. Alſo, after what has been taught in the foregoing propoſition, we may always ſuppoſe that we know the caſe $ap - bq = \pm 1$; it will therefore be ſufficient in this place to ſhew how the general values of x and y, in the equation $ax - by = \pm c$, may be deduced from the known caſe $ap - bq = \pm 1$.

In the firſt place it is obvious, that ſince

$$ap - bq = \pm 1,$$

we ſhall have

$$acp - bcq = \pm c;$$

but this furniſhes only one ſolution, and in order to have the general values of x and y, we muſt ſubſtitute $x = mb \pm cp$; and $y = ma \pm cq$; which give

$$a\,(mb \pm cp) - b\,(ma \pm cq) = \pm c;$$

the ambiguous ſign $\pm$, in the two values of x and y, being $+$ when $ap - bq$ has the ſame ſign with c, but $-$ when it has a contrary one.

Ex. 1.—Find the values of x and y, in the equation

$$9x - 13y = 10.$$

Firſt, in the equation $9p - 13q = \pm 1$, we have $p = 3$, and $q = 2$, which gives $9p - 13q = +1$; and this being the ſame ſign with 10 in the propoſed equation, the general values of x and y are

$$\left\{ \begin{array}{l} x = 13m + 3c, \text{ or} \\ x = 13m + 30; \end{array} \right. \text{ and } \left\{ \begin{array}{l} y = 9m + 2c, \text{ or} \\ y = 9m + 20 \end{array} \right.$$

And by aſſuming here $m = -2, -1, 0, 1, 2$, &c. we have the following values of x and y:

$$\begin{array}{lccccccc} m = & -2, & -1, & 0, & 1, & 2, & 3 & \&c. \\ x = & 4, & 17, & 30, & 43, & 56, & 69 & \&c. \\ y = & 2, & 11, & 20, & 29, & 38, & 47 & \&c. \end{array}$$

each of which values has the required conditions, for

$$\begin{array}{c} 9 \cdot 4 - 13 \cdot 2 = 10 \\ 9 \cdot 17 - 13 \cdot 11 = 10 \\ 9 \cdot 30 - 13 \cdot 20 = 10 \\ 9 \cdot 43 - 13 \cdot 29 = 10 \\ \text{-\&c.} \qquad \text{\&c.} \qquad \text{\&c.} \end{array}$$

Ex. 2.—Find the values of x and y, in the equation

$$7x - 12y = 19.$$

Firſt in the equation $7p - 12q = -1$, we have $p = 5$, and $q = 3$; where -1 has a different ſign from 19 in the propoſed equation; therefore the general values of x and y are

$$\left\{ \begin{array}{l} x = 12m - 5 \cdot 19; \\ x = 12m - \quad 95; \end{array} \right. \text{ and } \left\{ \begin{array}{l} y = 7m - 3 \cdot 19, \text{ or} \\ y = 7m - \quad 57 \end{array} \right.$$

where, by taking $m = 9, 10, 11$, &c. in order that x and y may be poſitive, we have

$$\begin{array}{lcccccccc} x = & 13, & 25, & 37, & 49, & 61, & 73, & 85 & \&c. \\ y = & 6, & 13, & 20, & 27, & 34, & 41, & 48 & \&c. \end{array}$$

and in a ſimilar manner may any poſſible equation $ax - by = \pm c$ be reſolved.

PROP. III.

To find the general values of x and y, in the equation

$$ax + by = c.$$

In the foregoing propoſition, where the difference of two quantities was the ſubject of conſideration, we found that the number of ſolutions was infinite, provided that a and b were prime to each other; but in conſidering the ſum of two quantities, as in the preſent caſe, the number of ſolutions is always limited, and in many caſes the equation is impoſſible; it may however be demonſtrated, that the equation always admits of at leaſt one ſolution, if $c > ab - a - b$, a and b being prime to each other; and it is propoſed in the preſent propoſition to aſcertain the exact number of poſſible ſolutions that any equation of this kind admits of in integer numbers, and to point out more accurately the limits of poſſibility.

The ſolution of the equation $ax + by = c$, depends, like that in the foregoing propoſition, upon the equation $ap - bq = \pm 1$, though its connection with it is not ſo readily perceived.

Let $ap - bq = 1$; then we have alſo

$$a . cp - b . cq = c;$$

and it is evident that we ſhall have the ſame reſult if we make

$$x = cp - mb; \text{ and } y = cq - ma;$$

for this alſo gives

$$a\ (cp - mb) - b\ (cq - ma) = c:$$

aſſuming, therefore, for m ſuch a value, that $cq - ma$ may become negative, while $cp - mb$ remains poſitive, we ſhall have

$$a\ (cp - mb) + b\ (ma - cq) = c;$$

and conſequently $x = cp - mb$; and $y = ma - cq$; but if m cannot be ſo taken that $cq - ma$ may be negative, while $cp - mb$ remains poſitive; it is a proof that the propoſed equation is impoſſible in integer numbers. And on the contrary, the equation will always admit of as many integral ſolutions as there may be different values given to m, ſuch that the above conditions may obtain.

And hence we are enabled to determine *à priori* the number of ſolutions that any propoſed equation of the above form admits of; for ſince we muſt have $cp > mb$, and $cq < ma$, the number of ſolutions will always be expreſſed by the greateſt integer contained in the expreſſion $\left(\frac{cp}{b} - \frac{cq}{a}\right)$; as is evident, becauſe m muſt be leſs than the firſt of thoſe fractions, and greater than the ſecond, and therefore, the difference between the integral part of theſe fractions will expreſs the number of different values of m; except when $\frac{cp}{b}$ is a complete integer, or, which is the ſame, we muſt conſider $\frac{b}{b}$ as a fraction, and reject it, but not $\frac{a}{a}$, the reaſon for which is obvious.

Ex. 1.—Required the values of x and y, in the equation

$$9x + 13y = 2000,$$

and the number of poſſible ſolutions in integers.

Firſt, in the equation $9p - 13q = 1$, we have at once $p = 3$, and $q = 2$; therefore the number of ſolutions will be expreſſed by

$$\frac{2000 \times 3}{13} - \frac{2000 \times 2}{9} = 461 - 444 = 17.$$

And theſe are readily obtained from the formulæ

$$\begin{cases} x = cp - mb, \text{ or} \\ x = 6000 - 13m; \end{cases} \text{ and } \begin{cases} y = ma - cq, \text{ or} \\ y = 9m - 4000 \end{cases}$$

in which, aſſuming $m = 445, 446,$ &c.; in order that $9m > 4000$, we ſhall have the following ſolutions, each of which is deduced from the preceding one, by adding ſucceſſively 9 to the values of y, and ſubtracting 13 from thoſe of x; thus

$$\begin{array}{llllllll} x = 215, & 202, & 189, & 176, & 163, & 150, & 137 & \text{\&c.} \\ y = 5, & 14, & 23, & 32, & 41, & 50, & 59 & \text{\&c.} \end{array}$$

that is;

$$\begin{array}{l} 9 . 215 + 13 . 5 = 2000 \\ 9 . 202 + 13 . 14 = 2000 \\ 9 . 189 + 13 . 23 = 2000 \\ 9 . 176 + 13 . 32 = 2000 \\ \quad\text{\&c.} \qquad \text{\&c.} \qquad \text{\&c.} \end{array}$$

Ex. 2.—Given the equation $11x + 13y = 190$, to find the number of ſolutions, and the values of x and y.

Firſt in the equation $11p - 13q = 1$, we have $p = 6$, and $q = 5$; therefore

$$\frac{190 . 6}{13} - \frac{190 . 5}{11} = 87 - 86 = 1;$$

whence it follows that the equation admits of only one integral ſolution, and this is obtained from the formulæ

$$\begin{cases} x = cp - mb, \text{ or} \\ x = 190 . 6 - 13m; \end{cases} \text{ and } \begin{cases} y = ma - cq, \text{ or} \\ y = 11m - 190 . 5 \end{cases}$$

where, by taking $m = 87$, in order that $ma - cq$ may be poſitive, we have $x = 9$, and $y = 7$, which gives

$$11 . 9 + 13 . 7 = 190, \text{ as required.}$$

PROP. IV.

To find the values of x, y, and z, and the number of integral ſolutions of any equation of the form

$$ax + by + cz = d.$$

In the firſt place we may obſerve, that if any one or more of the co-efficients a, b, or c, be negative, the number of anſwers is indefinite. For let b be negative, then the equation may be put under the form

$$ax + cz = by + d;$$

in which, by means of the indeterminate y, an infinite number of values may be given to the ſecond ſide of the equation; and conſequently alſo to x and y. We need, therefore, only conſider equations of the form above given, in which the quantities are all connected with the ſign +.

Now in this equation, as in thoſe of the two foregoing propoſitions, if a, b, and c, have each a common diviſor, which d has not, it becomes impoſſible; but if only two of them, as a and b, have a common meaſure, the equation is ſtill poſſible, as we ſhall ſee in what follows.

The ſolution of the equation,

$$ax + by + cz = d,$$

is reſolved by means of the equation

$$ap - bq = \pm 1,$$

as we have ſeen is the caſe in the preceding examples. For let one of the three terms, as cz, be tranſpoſed to the other ſide of the equation; then we have

$$ax + by = d - cz,$$

in which the values of x and y, determined as in the laſt propoſition, will be

$$x = (d - cz)\,p - mb; \text{ and } y = ma - (d - cz)\,q,$$

that is, by only ſubſtituting $d - cz$ inſtead of c, which is the only reſpect in which this equation differs from that in the foregoing problem: and here the only limits to be obſerved are,

1ſt, $cz < d$; 2d, $mb < (d - cz)\,p$; 3d, $ma > (d - cz)\,q$ by attending to which, all the poſſible values of x and y

may be obtained. But as theſe queſtions generally admit of a great number of ſolutions, the object of enquiry is not ſo much to find the values of the intermediate quantities, as to determine *à priori* the number of them that the equation admits of; and this, therefore, ſhall form the ſubject of our future inveſtigation.

Now we have ſeen, that in the equation

$$ax + by = c,$$

the number of ſolutions is generally expreſſed by

$$\frac{cp}{b} - \frac{cq}{a},$$

p and q being firſt determined by the equation

$$ap - bq = 1.$$

If, therefore, in the equation

$$ax + by = d - cz,$$

we make ſucceſſively $z = 1, 2, 3, 4,$ &c. the number of ſolutions for each value of z will be as below; *viz.*

$$ax + by = d - c, \text{ number of ſolutions } \frac{(d-c)p}{b} - \frac{(d-c)q}{a}$$

$$ax + by = d - 2c \text{ . . . . } \frac{(d-2c)p}{b} - \frac{(d-2c)q}{a}$$

$$ax + by = d - 3c \text{ . . . . } \frac{(d-3c)p}{b} - \frac{(d-3c)q}{a}$$

&c. &c. &c. &c.

the ſum of which will be the total number that the given equation admits of; and therefore, in order to find the exact number of ſolutions in any equation of this kind, we muſt firſt aſcertain the ſum of all the integral parts of the arithmetical ſeries

$$\begin{cases} \frac{(d-c)p}{b} + \frac{(d-2c)p}{b} + \frac{(d-3c)p}{b} + \frac{(d-4c)p}{b} + \&\text{c; and} \\ \frac{(d-c)q}{a} + \frac{(d-2c)q}{a} + \frac{(d-3c)q}{a} + \frac{(d-4c)q}{a} + \&\text{c; and} \end{cases}$$

the difference of the two will be the exact number of intregal ſolutions.

Now in both theſe ſeries, we know the firſt and laſt term, and the number of terms; for the general term being

$$\frac{(d-cz)p}{b}, \text{ and } \frac{(d-cz)q}{a},$$

we ſhall have the extreme terms by taking the extreme limits of z, that is $z = 1$, and $z < \frac{d}{c}$; which laſt value of z alſo expreſſes the number of terms in the ſeries.

Hence then, having the elements of the progreſſions given, the ſum of the whole ſeries is readily obtained; and if therefore we alſo find the ſum of the fractional parts in each, we ſhall have, by deducting it from the whole ſums, that of the integral part of the ſeries as required. The latter part of this problem is readily effected, for the denominator in each term being conſtant, the fractions will neceſſarily recur in periods; and the number in each can never exceed the denominator: it will therefore only be neceſſary to find the ſum of the fractions in one period, which being multiplied by the number of periods, will give the ſum of the fractional part of the terms; and theſe taken from the total ſum, will give the ſum of the integral part of the ſeries; and then, from what has been before obſerved, the difference of the two ſums will be the number of integral ſolutions required. It may alſo be obſerved, that when the number of terms do not conſiſt of an exact number of periods of circulation, the remaining terms or fractions muſt be ſummed by themſelves, which is alſo readily effected, as they will be the ſame as the leading terms of the firſt period; and it muſt alſo be remembered, that $\frac{b}{b}$ is to be conſidered as a fraction in the firſt ſeries; but not $\frac{a}{a}$ in the ſecond, as is explained in the foregoing propoſition.

Ex. 1.—Given $5x + 7y + 11z = 224$, to find the number of ſolutions that the equation admits of in poſitive integers.

Here the greateſt limit of z is $z < \frac{224}{11} = 20$: alſo in the equation $5p - 7q = 1$, we have $p = 3$, and $q = 2$, alſo $a = 5$, and $b = 7$; and therefore the two ſeries, of which the ſums are required, beginning with the leaſt term in each, are

$$\begin{cases} \frac{3 \cdot 4}{7} + \frac{3 \cdot 15}{7} + \frac{3 \cdot 26}{7} + \frac{3 \cdot 37}{7} + \&\text{c. . . . } \frac{3 \cdot 113}{7} \\ \frac{2 \cdot 4}{5} + \frac{2 \cdot 15}{5} + \frac{2 \cdot 26}{5} + \frac{2 \cdot 37}{5} + \&\text{c. . , . } \frac{2 \cdot 113}{5} \end{cases}$$

the common difference in the firſt being $\frac{3 \cdot 71}{7}$; and in the ſecond $\frac{2 \cdot 11}{5}$; alſo the number of terms in each 20.

Whence we have 930 for the ſum of the firſt;
and - - 868 for the ſum of the ſecond.

Again, the firſt period of fractions, in the firſt ſeries, is

$$\frac{5}{7} + \frac{3}{7} + \frac{1}{7} + \frac{6}{7} + \frac{4}{7} + \frac{2}{7} + \frac{7}{7} = 4;$$

and in the ſecond ſeries, the firſt period of fractions is

$$\frac{3}{5} + 0 + \frac{2}{5} + \frac{4}{5} + \frac{1}{5} = 2;$$

$\frac{7}{7}$ being conſidered as a fraction in the firſt, but not $\frac{5}{5}$ in the ſecond.

Now the number of terms in each ſeries being 20, we have 2 periods and 6 terms in the firſt ſeries $= 2 \times 4 +$ the firſt 6 fractions $= 11$ for the ſum of all the fractions; and therefore $930 - 11 = 919$, which is the exact ſum of the integral terms. And in the ſecond, we have 4 periods $= 4 \cdot 2 = 8$, and therefore $868 - 8 = 860$, which is the ſum of the integral terms in this; and hence according to the rule

$$919 - 860 = 59;$$

which is the number of integral ſolutions.

Remark.—Simpſon, in his algebra, makes the number of ſolutions to this queſtion 60; but he has evidently introduced one (*viz.* $x = 10$, $y = 14$, and $z = 14$,) which does not obtain.

Ex. 2.—Having given $7x + 9y + 23z = 9999$, it is required to find the number of its ſolutions in poſitive integers.

Here the greateſt limit of $z < \frac{9999}{23} = 434$; alſo in the equation $7x - 9p = 1$, we have $p = 4$, and $q = 3$,
$a =$,

$a = 7$, and $b = 9$; alſo $9999 - 23 \cdot 434 = 17$; therefore the ſeries whoſe ſums are required, will be

$$\text{1ſt. } \frac{4 \cdot 17}{9} + \frac{4 \cdot 40}{9} + \frac{4 \cdot 63}{9} + \text{\&c.} \ldots \frac{4 \cdot 9976}{9}$$

$$\text{2d. } \frac{3 \cdot 17}{7} + \frac{3 \cdot 40}{7} + \frac{3 \cdot 63}{7} + \text{\&c.} \ldots \frac{3 \cdot 9976}{7}$$

the common difference in the firſt being $\frac{4 \cdot 23}{9} = 10\frac{2}{9}$; and in the ſecond $\frac{3 \cdot 23}{7} = 9\frac{6}{7}$: alſo the number of terms in each 434; that being the greateſt limit of z.

Hence we have the ſum of the firſt ſeries $= 963769\frac{3}{9}$

and of the ſecond - - - - 929349

Alſo the firſt period of fractions in the firſt ſeries, is

$$\frac{5}{9} + \frac{7}{9} + \frac{9}{9} + \frac{2}{9} + \frac{4}{9} + \frac{6}{9} + \frac{8}{9} + \frac{1}{9} + \frac{3}{9} = 5;$$

and $\frac{434}{9} = 48$ periods, and 2 terms $= 5 \cdot 48 + \frac{5}{9} + \frac{2}{9} = 241\frac{3}{9}$

And in the ſecond ſeries, the firſt period of fractions is

$$\frac{2}{7} + \frac{1}{7} + 0 + \frac{6}{7} + \frac{5}{7} + \frac{4}{7} + \frac{3}{7} = 3;$$

alſo $\frac{434}{7} = 62$ periods; and therefore $62 \cdot 3 = 186$.

Hence $963769\frac{3}{9} - 241\frac{3}{9} = 963528$ integral terms

and $929349 - 186 = 929163$ integral terms

whence the difference 34365 is the number of integral ſolutions required.

In the foregoing examples we have had two of the terms prime to each other; but when this is not the caſe the following transformation will be neceſſary.

Ex. 3.—Let there be propoſed the equation,

$$12x + 15y + 20z = 100001,$$

to find the number of ſolutions.

Here no two of the co-efficients are prime to each other, and we muſt therefore proceed as follows.

Divide the whole equation by 3, and tranſpoſe z, and we have

$$4x + 5y = 33334 - 7z + \frac{z - 1}{3}$$

which laſt muſt be an integer; make therefore $\frac{z - 1}{3} = u$, and we have $z = 3u + 1$; ſubſtituting now this value of z, the original equation becomes

$$12x + 15y + 20(3u + 1) = 100001;$$

or, dividing by 3,

$$4x + 5y + 20u = 33327,$$

the number of ſolutions in which will be the ſame as in the equation propoſed, which will be found as in the foregoing examples, except that here the leaſt value of $u = 0$, becauſe we ſhall then ſtill have $z = 1$, and by proceeding as in the preceding examples, it will be found that the number of integral ſolutions that may be given to this queſtion, amounts to no leſs than 1388611.

PROP. V.

Having given any number of equations, leſs than the number of unknown quantities that enter therein, to determine thoſe quantities.

Let there be propoſed the two equations

$$\begin{cases} a x + b y + c z = d \\ a' x + b' y + c' z = d' \end{cases}$$

to find the values of x, y, and z.

Multiply the firſt by a', and the ſecond by a, whence, by ſubtraction, we obtain

$$(a b - a b') y + (a' c - a c') z = a' d - a d'$$

Or, dividing each of theſe known co-efficients by their greateſt common diviſor, if they have any, and repreſenting the reſults by b'', c'', and d'', this equation becomes

$$b'' y + c'' z = d''.$$

Find now the values of y and z in this equation; and theſe being ſubſtituted for them in the equation

$$x = \frac{d - c z - b y}{a}$$

will give the correſponding values of x, of which thoſe, of courſe, muſt be rejected that render x fractional, and alſo thoſe that give $(c z + b y) > d$.

Ex.—Given the equations

$$\begin{cases} 3x + 5y + 7z = 560 \\ 9x + 25y + 49z = 2920 \end{cases}$$

to find all the integral values of x, y, and z.

Multiplying the firſt by 3, we have

$$\begin{cases} 9x + 15y + 21z = 1680 \\ 9x + 25y + 49z = 2920 \end{cases}$$

whence

$$\begin{cases} 10y + 28z = 1240, \text{ or} \\ 5y + 14z = 620 \end{cases}$$

And here the values of y and z are found to be

$$\begin{aligned} y &= 110,\ 96,\ 82,\ 68,\ 54,\ 40,\ 26,\ 12 \\ z &= 5,\ 10,\ 15,\ 20,\ 25,\ 30,\ 35,\ 40 \end{aligned}$$

and of theſe, the only two that give

$$x = \frac{560 - 7z - 5y}{3}$$

an integer, are as follows,

$$\begin{cases} z = 15,\ y = 82,\ x = 15 \\ z = 30,\ y = 40,\ x = 50 \end{cases}$$

which are the only two ſolutions the equations admit of in integers.

The method above given will never fail of producing all the poſſible ſolutions in equations of the above form; but there are other methods that may be followed in particular caſes which ſometimes ſhorten the operations. Theſe the reader will find explained in vol. ii. of Euler's Elements of Algebra.

PROP. VI.

To decompoſe a given numeral fraction, having a compoſite denominator, into a number of ſimple fractions having prime denominators.

This is, in fact, only an application of the foregoing propoſitions to this particular problem; for let $\frac{m}{n}$ be the given fraction; and ſuppoſe, in the firſt inſtance, that its denominator conſiſts of two prime factors, or $n = a\,b$, it will then be to find

$$\frac{m}{a\,b} = \frac{p}{a} + \frac{q}{b}\text{, or } a\,q + b\,p = m,$$

in which equation, having determined the values of p and q, we ſhall have $\frac{p}{a} + \frac{q}{b}$ for the fractions required; and as many different ways may any ſuch fraction be decompoſed into two others, as the equation $a\,q + b\,p = m$ admits of integral ſolutions. If the given fraction be $\frac{m}{a\,b\,c}$, then we may firſt reſolve it into two fractions, and one of theſe into two others; thus, let

$$\frac{m}{a\,b\,c} = \frac{p}{a\,b} + \frac{q}{c};$$

then we have

$$a\,b\,q + c\,p = m;$$

and having, from this equation, found the values of p and q, we ſhall have $\frac{m}{a\,b\,c} = \frac{p}{a\,b} + \frac{q}{c}$.

Again, let $\frac{p}{a\,b} = \frac{r}{a} + \frac{s}{b}$, or $a\,s + r\,b = p$, find r and s in this equation, ſo ſhall we have

$$\frac{m}{a\,b\,c} = \frac{r}{a} + \frac{s}{b} + \frac{q}{c},$$

as required; and in the ſame manner may any fraction that admits of decompoſition be reſolved into others of which the ſum ſhall be equal to the original fraction.

Ex.—What are thoſe two fractions whoſe ſum is equal to $\frac{19}{35}$.

Since $35 = 5 \times 7$, we may make $\frac{19}{35} = \frac{p}{7} + \frac{q}{5}$, which produces this equation,

$$5\,p + 7\,q = 19,$$

in which the value of $p = 1$, and $q = 2$ are readily found; and therefore the fractions ſought are $\frac{1}{7} + \frac{2}{5} = \frac{19}{35}$.

Prop. VII.

To find the leaſt number, that, being divided by given numbers, ſhall leave given remainders.

Let N repreſent the required number, ſuch that, being divided by a, a', a'' &c. the remainders ſhall be reſpectively b, b', b'', &c. that is,

$$N = a\,m + b = a'\,n + b' = a''\,p + b''\ \&c.$$

and it is required to find the leaſt value of N, that anſwers theſe conditions.

First ſince $\quad a\,m + b = a'\,n + b'$
we have $\quad a\,m - a'\,n = b' - b.$

Find, therefore, in this equation, the leaſt values of m and n by Prop. II., then will $a\,m + b$, or $a'\,n + b'$, expreſs the leaſt number that fulfils the firſt two conditions. Let now this number be called c; then it is evident that every number of the form $a\,a'\,q + c$ will alſo fulfil theſe conditions; and we muſt proceed to find $a\,a'\,q + c = a''\,p + b''$; or,

$$a\,a'\,q - a''\,p = b'' - c;$$

that is, the leaſt value of p and q in this equation; ſo ſhall we have $a\,a'\,q + c$ for the leaſt number that anſwers the firſt three conditions, and ſo on for as many others as may be propoſed.

Ex.—Find the leaſt number, that, being divided by 28, 19, and 15, ſhall leave for remainders reſpectively 19, 15, and 11.

Here we have $28\,m + 19 = 19\,n + 15 = 15\,p + 11$. Now, in the equation $28\,m - 19\,n = -4$, the leaſt values of m and n are $m = 8$, and $n = 12$; whence $28\,m + 19 = 19\,n + 15 = 243$; and it now remains to find $28 \,.\, 19\,q + 243 = 15\,p + 11$; or, $532\,q - 15\,p = -228$.

In which equation $p = 512$, and $q = 14$, whence $532\,q + 243 = 15\,p + 11 = 7691$, which is the leaſt number having the required conditions.

Having thus treated of the ſolution of indeterminate equations of the firſt degree, to as great an extent as our limit will admit of, we ſhall proceed to thoſe, in which one, at leaſt, of the unknown quantities enter in the ſquare power, which conſtitute the claſs of indeterminate equations of the ſecond degree; and as we have ſeen that every equation of the firſt claſs has its ſolution depending upon that of the equation $a\,p - b\,q = \pm 1$; ſo in thoſe that we are about to inveſtigate, the ſolution is intimately connected with that of the equation $p^2 - N\,q^2 = \pm 1$; this, therefore, is what ſhall firſt engage our attention.

Prop. VIII.

To find the integral values of p and q in the equation

$$p^2 - N\,q^2 = \pm 1,$$

N being any given number whatever, not a complete ſquare.

In order to obtain the general ſolution of this equation, which is always poſſible (at leaſt with the poſitive ſign) we muſt ſhew the method of extracting the ſquare root of any number N, not a complete ſquare, in continued fractions; but as this operation belongs properly to the latter ſubject, we ſhall only in this place indicate the method, and muſt refer the reader for the demonſtration to vol. ii. of Euler's Algebra, and to Barlow's Elementary Inveſtigations. See alſo Square Root.

The transformation of the $\sqrt{N}$, to continued fractions, is performed by means of the following formula.

Let a be the greateſt integer contained in $\sqrt{N}$; then make

$$\begin{array}{ll|rl}
\dfrac{\sqrt{N} + 0}{1} = a & & a - 0 = m; & \dfrac{N - m^2}{1} = n \\
\dfrac{\sqrt{N} + m}{n} = u & & u\,n - m = m'; & \dfrac{N - m'^2}{n} = n' \\
\dfrac{\sqrt{N} + m'}{n'} = u' & & u'\,n' - m' = m''; & \dfrac{N - m''^2}{n'} = n'' \\
\dfrac{\sqrt{N} + m''}{n''} = u'' & & u''\,n'' - m'' = m'''; & \dfrac{N - m'''^2}{n''} = n''' \\
\&c. & \&c. & \&c. & \&c.
\end{array}$$

In theſe formulæ u, u', u'', &c. are the greateſt integers contained in the correſponding fractions, which quantities are the quotients, whence the converging fractions are to be deduced, by the ſame rule as is given in Prop. I. for the quotients α, β, γ, δ, &c.; and by continuing the above operations, we ſhall be finally led to a quotient equal to $2\,a$, at which term we muſt ſtop, and the correſponding fractions to the laſt quotient before this will give the required values of p and q.

Ex. 1.—Required the values of p and q in the equation

$$p^2 - 19q^2 = -1.$$

By the above rule,

$$\begin{array}{l|l}
\frac{\surd 19 + 0}{1} = 4 = a & 4 \cdot 1 - 0 = 4\,; \ \frac{19 - 4^2}{1} = 3 \\
\frac{\surd 19 + 4}{3} = 2 = u & 3 \cdot 2 - 4 = 2\,; \ \frac{19 - 2^2}{3} = 5 \\
\frac{\surd 19 + 2}{5} = 1 = u' & 5 \cdot 1 - 2 = 3\,; \ \frac{19 - 3^2}{5} = 2 \\
\frac{\surd 19 + 3}{2} = 3 = u'' & 2 \cdot 3 - 3 = 3\,; \ \frac{19 - 3^2}{2} = 5 \\
\frac{\surd 19 + 3}{5} = 1 = u''' & 5 \cdot 1 - 3 = 2\,; \ \frac{19 - 2^2}{5} = 3 \\
\frac{\surd 19 + 2}{3} = 2 = u^{\text{iv}} & 3 \cdot 2 - 2 = 4\,; \ \frac{19 - 4^2}{3} = 1 \\
\frac{\surd 19 + 4}{1} = 8 = u^{\text{v}} & \&\text{c.} \qquad \&\text{c.}
\end{array}$$

Having thus arrived at the quotient $8 = 2a$, we have only to compute the fractions by the propoſition above quoted; thus,

$$\begin{array}{llllllll}
\text{quotients} & 4, & 2, & 1, & 3, & 1, & 2, & 8 \\
\text{fractions} \left\{ \right. & \frac{4}{1} & \frac{9}{2} & \frac{13}{3} & \frac{48}{11} & \frac{61}{14} & \frac{170}{39} &
\end{array}$$

which laſt fraction gives the values of p and q; that is, $p = 170$, and $q = 39$; for

$$170^2 - 19 \cdot 39^2 = -1, \text{ as required.}$$

Ex. 2.—Find the values of p and q in the equation

$$p^2 - 13q^2 = -1.$$

Firſt,

$$\begin{array}{l|l}
\frac{\surd 13 + 0}{1} = 3 & 3 \cdot 1 - 0 = 3\,; \ \frac{13 - 3^2}{1} = 4 \\
\frac{\surd 13 + 3}{4} = 1 & 4 \cdot 1 - 3 = 1\,; \ \frac{13 - 1^2}{4} = 3 \\
\frac{\surd 13 + 1}{3} = 1 & 3 \cdot 1 - 1 = 2\,; \ \frac{13 - 2^2}{3} = 3 \\
\frac{\surd 13 + 2}{3} = 1 & 3 \cdot 1 - 2 = 1\,; \ \frac{13 - 1^2}{3} = 4 \\
\frac{\surd 13 + 1}{4} = 1 & 4 \cdot 1 - 1 = 3\,; \ \frac{13 - 3^2}{4} = 3 \\
\frac{\surd 13 + 3}{1} = 6 & \&\text{c.} \qquad \&\text{c.}
\end{array}$$

And having thus arrived at the quotient $2a$, or 6, we have for

$$\begin{array}{llllll}
\text{quotients} & 3, & 1, & 1, & 1, & 1 \\
\text{fractions} \left\{ \right. & \frac{3}{1} & \frac{4}{1} & \frac{7}{2} & \frac{11}{3} & \frac{18}{5}
\end{array}$$

that is, $p = 18$ and $q = 5$, which give

$$18^2 - 13 \cdot 5^2 = -1,$$

as required.

Ex. 3.—Find the values of p and q in the equation

$$p^2 - 17q^2 = -1.$$

$$\text{Firſt } \frac{\surd 17 + 0}{1} = 4 = a \quad \left\{ 4 - 0 = 4 \cdot \frac{17 - 4^2}{1} = 1 \right.$$

$$\frac{\surd 17 + 4}{1} = 8$$

Here we have, at the firſt ſtep, arrived at the quotient $2a$, whence the firſt fraction, $\frac{4}{1}$, is the one ſought; for $4^2 - 17 \cdot 1^2 = -1$, as required.

Ex. 4.—Find the values of p and q in the equation

$$p^2 - 14q^2 = 1.$$

Firſt,

$$\begin{array}{l|l}
\frac{\surd 14 + 0}{1} = 3 & 3 \cdot 1 - 0 = 3\,; \ \frac{14 - 3^2}{1} = 5 \\
\frac{\surd 14 + 3}{5} = 1 & 5 \cdot 1 - 3 = 2\,; \ \frac{14 - 2^2}{5} = 2 \\
\frac{\surd 14 + 2}{2} = 2 & 2 \cdot 2 - 2 = 2\,; \ \frac{14 - 2^2}{2} = 5 \\
\frac{\surd 14 + 2}{5} = 1 & 5 \cdot 1 - 2 = 3\,; \ \frac{14 - 3^2}{5} = 1 \\
\frac{\surd 14 + 3}{1} = 6 & \quad \&\text{c.} \qquad \&\text{c.}
\end{array}$$

Whence we have,

$$\begin{array}{lllll}
\text{quotients} & 3, & 1, & 2, & 1 \\
\text{fractions} \left\{ \right. & \frac{3}{1} & \frac{4}{1} & \frac{11}{3} & \frac{15}{4}
\end{array}$$

which gives $15^2 - 14 \cdot 4^2 = 1$, as required.

It will be obſerved, that in the foregoing examples we have obtained for each only one ſolution; whereas they all admit of an indefinite number of ſolutions. Moreover, it does not appear, from the firſt three examples, how we ſhould have found the values of p and q, if they had been put equal to $+1$ inſtead of -1. This ſhall, therefore, be conſidered in the following propoſition.

Prop. IX.

To find the general values of x and y in the equation $x^2 - Ny^2 = \pm 1$, from one known caſe $p^2 - Nq^2 = \pm 1$. In the firſt place it may be demonſtrated, but our limits will not allow of it, that the equation $x^2 - Ny^2 = 1$ is always poſſible for every value of N, providing it be not a complete ſquare; and the values of x and y are always deducible, both from $p^2 - Nq^2 = 1$, and from $p^2 - Nq^2 = -1$; but if the operation above given does not produce the equation $p^2 - Nq^2 = -1$, the equation $x^2 - Ny^2 = -1$ is always impoſſible. The preſent problem, therefore, divides itſelf into three caſes; *viz.* to find the general values of x and y in the equation $x^2 - Ny^2$, under the following conditions:

1ſt, $x^2 - Ny^2 = 1$, from one known caſe $p^2 - Nq^2 = 1$
2d, $x^2 - Ny^2 = 1$, $p^2 - Nq^2 = -1$
3d, $x^2 - Ny^2 = -1$, $p^2 - Nq^2 = -1$

Caſe 1.—Reſolve $p^2 - Nq^2 = 1$, and $x^2 - Ny^2 = 1$ into the factors $\left\{ \begin{array}{l} (p + q\surd N)\,(p - q\surd N) = 1 \\ (x + y\surd N)\,(x - y\surd N) = 1 \end{array} \right.$

then we have alſo,

$$(p + q\surd N)^m\,(p - q\surd N)^m = 1;$$

equating theſe, with the factors in x and y, we have

$$\begin{aligned} (p + q\surd N)^m &= x + y\surd N \\ (p - q\surd N)^m &= x - y\surd N \end{aligned}$$

$$\text{whence } x = \frac{(p + q\surd N)^m + (p - q\surd N)^m}{2};$$

$$\text{and} \quad y = \frac{(p + q\surd N)^m - (p - q\surd N)^m}{2\surd N};$$

which values of x and y will always be integral, and will be the general values ſought; and theſe are evidently indefinite in number, becauſe the power m is indefinite.

Caſe 2.—The ſame method may be followed here, as in the preceding caſe, except that the powers muſt be even, in order to convert -1 into $+1$, as is obvious from inſpection; and, therefore, the general values of x and y will be

$$\begin{cases} x = \dfrac{(p + q\sqrt{N})^{2m} + (p - q\sqrt{N})^{2m}}{2} \\ y = \dfrac{(p + q\sqrt{N})^{2m} - (p - q\sqrt{N})^{2m}}{2\sqrt{N}} \end{cases}$$

Caſe 3.—Here, again, we have evidently the ſame reſult as in the former caſes, except that the power m muſt now be odd for every odd power of $-1 = -1$; therefore,

$$\begin{cases} x = \dfrac{(p + q\sqrt{N})^{2m+1} + (p - q\sqrt{N})^{2m+1}}{2} \\ y = \dfrac{(p + q\sqrt{N})^{2m+1} - (p - q\sqrt{N})^{2m+1}}{2\sqrt{N}} \end{cases}$$

Let us now propoſe an example in each of theſe three caſes.

Ex. 1.—In the equation $p^2 - 14q^2 = 1$, we have $p = 15$ and $q = 4$, to find a ſecond value of p and q, or of x and y, in the equation $x^2 - 14y^2 = 1$.

Make

$$\begin{cases} x = \dfrac{(15 + 4\sqrt{14})^2 - (15 - 4\sqrt{14})^2}{2} = 449 \\ y = \dfrac{(15 + 4\sqrt{14})^2 - (15 - 4\sqrt{14})^2}{2\sqrt{14}} = 120 \end{cases}$$

which give $449^2 - 14 \cdot 120^2 = 1$; and other values may be found by aſſuming any other power above the ſecond.

Ex. 2.—Given $p = 4$, and $q = 1$, in the equation $p^2 - 17q^2 = -1$, to find the values of x and y, in the equation $x^2 - 17y^2 = 1$.

Here we have, again,

$$\begin{cases} x = \dfrac{(4 + \sqrt{17})^2 + (4 - \sqrt{17})^2}{2} = 33 \\ y = \dfrac{(4 + \sqrt{17})^2 - (4 - \sqrt{17})^2}{2\sqrt{17}} = 8 \end{cases}$$

whence $33^2 - 17 \cdot 8^2 = 1$; and other values may be found by aſſuming any other even power inſtead of the ſecond.

Ex. 3.—Given $p = 4$, and $q = 1$, in the equation $p^2 - 17q^2 = 1$, to find the values of x and y, in the equation $x^2 - 17y^2 = -1$.

Aſſume

$$\begin{cases} x = \dfrac{(4 + \sqrt{17})^3 + (4 - \sqrt{17})^3}{2} = 268 \\ y = \dfrac{(4 + \sqrt{17})^3 - (4 - \sqrt{17})^3}{2\sqrt{17}} = 67 \end{cases}$$

whence, $268^2 - 17 \cdot 67^2 = -1$, and other values may be obtained, by aſſuming other odd powers inſtead of the third.

PROP. X.

To aſcertain the poſſibility or impoſſibility of every equation of the form $x^2 - Ny^2 = \pm A$; and to find x and y in the former caſe, A being $< \sqrt{N}$.

The rule for this purpoſe, is to convert $\sqrt{N}$ into a ſeries of quotients, as in Prop. VIII.; and if A be found in the denominator of any of the quotients, that is, if A be found amongſt any of the numbers, which in the propoſition above quoted are repreſented by n, n', n'', &c. the equation is poſſible, and the converging fraction correſponding to the quotient preceding this will give the values of x and y; but if A be not ſo found, then is the equation impoſſible. This theorem cannot be demonſtrated in this place, as it belongs to the theory of continued fractions, and the reader is therefore referred for a proof of the rule to Le Gendre's Eſſai ſur la Theorie des Nombres.

Ex. 1.—Required the values of x and y, in the equation

$$x^2 - 23y^2 = 2.$$

Here by the rule Prop. VIII.

$$\begin{array}{l|ll} \dfrac{\sqrt{23} + 0}{1} = 4 & 1 \cdot 4 - 0 = 4; & \dfrac{23 - 4^2}{1} = 7 \\ \dfrac{\sqrt{23} + 4}{7} = 1 & 7 \cdot 1 - 4 = 3; & \dfrac{23 - 3^2}{7} = 2 \\ \dfrac{\sqrt{23} + 1}{2} = 3 & & \end{array}$$

Having thus arrived at the denominator 2, it follows that the equation is poſſible, and the values of x and y are found from the ſame calculation as at Prop. VIII.; thus,

$$\begin{array}{lccc} \text{quotients} & 4, & 1, & 3 \\ \text{fractions} & \dfrac{4}{1}, & \dfrac{5}{1}, & \end{array}$$

whence $x = 5$, and $y = 1$, which gives $x^2 - 23y^2 = 2$.

Ex. 2.—Required the values of x and y, in the equation

$$x - 19y^2 = 5.$$

Firſt

$$\begin{array}{l|ll} \dfrac{\sqrt{19} + 0}{1} = 4 & 1 \cdot 4 - 0 = 4; & \dfrac{19 - 4^2}{1} = 3 \\ \dfrac{\sqrt{19} + 4}{3} = 2 & 3 \cdot 2 - 4 = 2; & \dfrac{19 - 2^2}{3} = 5 \\ \sqrt{19} + 2 = 1 & & \end{array}$$

Having therefore found the denominator 5, the equation is poſſible, and we have

$$\begin{array}{lccc} \text{quotients} & 4, & 2, & 1 \\ \text{fractions} & \dfrac{4}{1}, & \dfrac{9}{2}, & \end{array}$$

whence $x = 9$, and $y = 2$, which gives $9^2 - 19 \cdot a^2 = 5$, as required.

Ex. 3.—It is required to aſcertain the poſſibility, or impoſſibility, of the equations

$$\begin{cases} x^2 - 17y^2 = \pm 2 \\ x^2 - 17y^2 = \pm 3 \end{cases}$$

Firſt

$$\begin{array}{l|ll} \dfrac{\sqrt{17} + 0}{1} = 4 & 1 \cdot 4 - 0 = 4; & \dfrac{17 - 4^2}{1} = 1 \\ \dfrac{\sqrt{17} + 4}{1} = 8 & 1 \cdot 8 - 4 = 4; & \dfrac{17 - 4^2}{1} = 1 \\ \dfrac{\sqrt{17} + 4}{1} = 8 & 1 \cdot 8 - 4 = 4; & \dfrac{17 - 4^2}{1} = 1 \end{array}$$

whence it follows, that ſince only 1 enters into the denominators of theſe quotients, no one of the propoſed equations are poſſible.

Cor.—By means of this propoſition, we may demonſtrate generally the impoſſibility of all equations falling under any of the following forms;

$$\begin{aligned} x^2 - (a^2 + 1)\,y^2 &= \pm A \\ x^2 - (a^2 - 1)\,y^2 &= \pm A \\ x^2 - (a^2 + a)\,y^2 &= \pm A \\ x^2 - (a^2 - a)\,y^2 &= \pm A \end{aligned}$$

in which $A > 1$, and $< a$.

Cor. 2.—It is alſo deducible from ſimilar principles, that the following equations are always poſſible; N being a prime number, of the form placed oppoſite the reſpective equations.

$x^2 - \mathrm{N}\,y^2 = -1$ poſſible when N of the form $4n + 1$
$x^2 - \mathrm{N}\,y^2 = -2$ . . . . . . N . . . . . . $8n + 3$
$x^2 - \mathrm{N}\,y^2 = \;\;2$ . . . . . . N . . . . . . $8n - 1$

And in a ſimilar manner, are deduced the three following theorems:

1. If M and N be both of the form $4n + 3$, and not equal to each other, the equation

$$\mathrm{M}\,x^2 - \mathrm{N}\,y^2 = \pm 1$$

is always poſſible in integer numbers: that is, under one or other of the ſigns + or −.

2. If M and N be both of the form $4n + 1$; then one of the equations

$$\begin{cases} x^2 - \mathrm{M\,N}\,y^2 = -1, \text{ or} \\ \mathrm{M}\,x^2 - \mathrm{N}\,y^2 = \pm 1 \end{cases}$$

will always be reſolvible in integers.

3. If M and M′ be two prime numbers of the form $4n + 3$, and N a prime number of the form $4n + 1$, it will be always poſſible to ſatisfy one of the equations

$$\begin{cases} \mathrm{N}\,x^2 - \mathrm{M\,M'}\,y^2 = \pm 1 \\ \mathrm{M}\,x^2 - \mathrm{M'\,N}\,y^2 = \pm 1 \\ \mathrm{M'}\,x^2 - \mathrm{M\,N}\,y^2 = \pm 1 \end{cases}$$

PROP. XI.

To find the general values of x and y in the equation

$$x^2 - \mathrm{N}\,y^2 = \pm \mathrm{A}$$

from one known caſe $p^2 - \mathrm{N}\,q^2 = \pm \mathrm{A}$.

Find the values of m and n in the equation $m^2 - \mathrm{N}\,n^2 = 1$, by Prop. VIII.; then it is evident that the product

$$(p^2 - \mathrm{N}\,q^2) \times (m^2 - \mathrm{N}\,n^2) = \pm \mathrm{A};$$

and it will be found, upon the developement of the following formulæ, that

$$(p^2 - \mathrm{N}\,q^2) \times (m^2 - \mathrm{N}\,n^2) = \begin{cases} (pm + \mathrm{N}qn)^2 - \mathrm{N}\,(pn + qm)^2 \\ (pm - \mathrm{N}qn)^2 - \mathrm{N}\,(pn - qm)^2 \end{cases}$$

we have, therefore, only to make,

$$\begin{cases} x = pm + \mathrm{N}\,qn \\ y = pn + qm \end{cases} \text{ or } \begin{cases} x = pm - \mathrm{N}\,qn \\ y = pn - qm \end{cases}$$

and having before ſhewn how to find the general values m and n in the equation $m^2 - \mathrm{N}\,n^2 = 1$; it is obvious, that by means of theſe formulæ we may derive different values of x and y, in the propoſed equation, to any extent at pleaſure.

Cor.—It appears alſo from this propoſition, that if the rule in the foregoing one give $p^2 - \mathrm{N}\,q^2 = -\mathrm{A}$, when the equation propoſed be $+\mathrm{A}$; that this may be converted to the latter ſign by means of the equation

$$m^2 - \mathrm{N}\,n^2 = -1.$$

Ex. 1.—Given the values of p and q, in the equation $p^2 - 7\,q^2 = 2$; *viz.* $p = 3$, and $q = 1$, to find the general values of x and y, in the equation $x^2 - 7\,y^2 = 2$.

Firſt in the expreſſion $m^2 - 7\,n^2 = 1$, we have $m = 8$, and $n = 3$; whence by the above formulæ is obtained

$$\begin{cases} x = pm \pm \mathrm{N}\,qn = 3 \cdot 8 \pm 7 \cdot 1 \cdot 3 = 3 \text{ or } 45 \\ y = pn \pm qm \;\;\; = 3 \cdot 3 \pm 1 \cdot 8 \;\;\; = 1 \text{ or } 17 \end{cases}$$

ſo that the ſecond values of x and y are, $x = 45$, and $y = 17$; which give $45^2 - 7 \cdot 17^2 = 2$. And aſſuming theſe again as new values of p and q, other values x and y may be found *in infinitum*: or the original values of p and q may be retained, and new values found for m and n, which anſwers the ſame purpoſe.

Ex. 2.—Find the general values of x and y, in the equation $x^2 - 11\,y^2 = 5$; the known caſe being $p^2 - 11\,q^2 = 5$, or $p = 4$, and $q = 1$.

In the equation $m^2 - 11\,n^2 = 1$, we have $m = 10$, and $n = 3$, therefore by the formulæ

$$\begin{cases} x = pm \pm \mathrm{N}\,qn = 4 \cdot 10 \pm 11 \cdot 1 \cdot 3 = 7 \text{ or } 73 \\ y = pn \pm qm \;\;\; = 4 \cdot 3 \pm 1 \cdot 10 \;\;\; = 2 \text{ or } 22 \end{cases}$$

that is $x = 7$, and $y = 2$, are two new values of x and y, as are alſo $x = 73$, and $y = 22$; for each of theſe give

$$\begin{cases} 7^2 - 11 \cdot 2^2 = 5 \\ 73^2 - 11 \cdot 22^2 = 5 \end{cases}$$

and in the ſame manner, other values may be found to any required extent.

As our limits will not allow of a very full and explicit inveſtigation of the ſeveral elegant rules that have been introduced into the indeterminate analyſis by Euler, Lagrange, Legendre, and other diſtinguiſhed mathematicians; we muſt refer the reader for the inveſtigation of the methods employed in the following propoſitions to the authors abovementioned, and muſt content ourſelves with barely ſtating the operations, without entering into the demonſtration of the theorems themſelves.

PROP. XII.

Every indeterminate equation of the ſecond degree falls under the general formula

$$a\,x^2 + b\,xy + c\,y^2 + d\,x + e\,y + f = 0,$$

and this may always be transformed to the more ſimple form

$$u^2 - \mathrm{A}\,t^2 = \mathrm{B}.$$

The method of performing this transformation will be ſeen from the following partial example, and the formulæ we have given it being univerſally the ſame in all caſes.

Aſſume $bd - 2ae = g$; $d^2 - 4af = h$; $(by + d)^2 - 4a\,(cy^2 + ey + f) = t$; $b^2 - 4ac = \mathrm{A}$; $\mathrm{A}y + g = u$; $g^2 - \mathrm{A}h = \mathrm{B}$.

Then it will be found, by the developement of theſe expreſſions, that

$$a\,x^2 + b\,xy + c\,y^2 + d\,x + e\,y + f = u^2 - \mathrm{A}\,t^2 - \mathrm{B} = 0,$$

becomes $$u^2 - \mathrm{A}\,t^2 = \mathrm{B}.$$

And having found the values of u and t in this laſt equation, thoſe of x and y are readily derived in the equation propoſed.

For $$y = \frac{u - g}{\mathrm{A}}, \text{ and } x = \frac{t - d - by}{2a};$$

or, ſubſtituting for y in the laſt, we have the following values;

$$\begin{cases} y = \dfrac{u - g}{b^2 - 4ac} \\ x = \dfrac{(t - d)\,(b^2 - 4ac) - (u - g)\,b}{2a\,(b^2 - 4ac)} \end{cases}$$

Ex. 1.—Transform the equation

$$3\,x^2 + 8\,xy - 3\,y^2 + 2\,x - 5\,y = 110$$

to its ſimpleſt form.

Here $a = 3$, $b = 8$, $c = -3$, $d = 2$, $e = -5$, $f = -110$.

Whence $$\begin{cases} b^2 - 4ac = \mathrm{A} = 100 \\ bd - 2ae = g = 46 \\ d^2 - 4af = h = 1324 \\ g^2 - \mathrm{A}h = \mathrm{B} = -130284 \end{cases}$$

and thus the reduced equation becomes

$$u^2 - 100t^2 = -130284.$$

In which, having found $u = 346$, and $t = 50$,

$$\text{we have}\left\{\begin{aligned} y &= \frac{u-g}{A} = \frac{346-46}{100} = 3, \\ x &= \frac{t-by-d}{2a} = \frac{50-8 \cdot 3-2}{6} = 4, \end{aligned}\right.$$

therefore $x = 4$, and $y = 3$, are the values of x and y in the original equation.

It will be obſerved that we have employed here the moſt general form that equations of this kind admit of, and therefore the formulæ are more complex than they uſually occur in practical caſes, for when any of the co-efficients a, b, c, &c. become zero, the expreſſions are much ſimplified, as appears from the following example.

Ex. 2.—Reduce $7x^2 + 5xy + y^2 = 67$ to its ſimpleſt form.

Here $a = 7$, $b = 5$, $c = 1$, $d = 0$, $e = 0$, $f = -67$, whence, omitting thoſe quantities that are zero, we have

$$\left\{\begin{aligned} & b^2 - 4ac = A = 29; \text{ and } g = 0 \\ & d^2 - 4af = h = 1876 \\ & g^2 - Ah^2 = 29 \cdot 1876^2 = B \end{aligned}\right.$$

and thus the reduced equation is

$$u^2 - 29t^2 = 29 \cdot 1876^2.$$

And in a ſimilar manner may any indeterminate equation of the ſecond degree be reduced to the form $u^2 - At^2 = B$.

Having therefore ſhewn the method of reducing every indeterminate equation to the form $u^2 - At^2 = B$; it follows that the ſolution of this ſimple form involves with it the ſolution of every equation of this kind that can be propoſed; we ſhall therefore, in the following propoſition, attend to the ſolution of this particular caſe. But it may be proper to ſtate, that there are an infinite number of equations of this kind that are impoſſible; and will admit of no ſolution, either in integers or fractions; and therefore before we proceed farther in the inveſtigation, it will be uſeful to lay down a rule, whence their poſſibility, or impoſſibility, may be aſcertained; as we may thus frequently ſave much unneceſſary labour.

Prop. XIII.

To aſcertain the poſſibility or impoſſibility of every indeterminate equation of the ſecond degree.

Rule.—Reduce the propoſed equation to the form

$$u^2 - At^2 = B,$$

and find all the remainders ariſing from dividing each of the ſquares 1^2, 2^2, 3^2, 4^2, &c. $\left(\frac{A-1}{2}\right)^2$ by A;

and alſo the remainders ariſing from dividing each of the ſquares 1^2, 2^2, 3^2, 4^2, &c. $\left(\frac{B-1}{2}\right)^2$ by B;

and again, divide the greateſt of theſe numbers A, B, by the leaſt of them, and obſerve the remainder.

Then if B be greater than A, this laſt remainder will be found amongſt thoſe of the upper ſeries; and the number A will be found amongſt thoſe of the lower ſeries, if the equation be poſſible.

And converſely, if theſe conditions have not place, the propoſed equation will admit of no ſolution, either in integers or fractions.

Again, if $A > B$, then the remainder ariſing from $\frac{A}{B}$ will be found in the lower ſeries, and the number B in the upper ſeries of remainders, if the equation be poſſible; and if theſe conditions have not place, the propoſed equation is impoſſible.

Note.—It is to be obſerved, that equations falling under the poſſible form are not always ſolvible in integers, the proof extending only to their ſolvibility in rational numbers, which may therefore ſometimes be fractional; but when they fall under an impoſſible form, they will admit of no ſolutions either in integers or fractions.

Ex.—Required the poſſibility or impoſſibility of the equation

$$x^2 - 7y^2 = 11$$

ſquares 1^2, 2^2, 3^2 divided by 7
remainders 1, 4, 2

ſquares 1^2, 2^2, 3^2, 4^2, 5^2 divided by 11
remainders 1, 4, 9, 5, 3

$\frac{11}{7} = 1$ and remainder 4.

Now 4 is found in the upper ſeries of remainders, but 7 is not found in the lower; therefore the equation cannot have place either in integers or fractions.

And for the ſame reaſon, the equation $x^2 - 7y^2 = 11z^2$ is alſo impoſſible, for if this was poſſible, ſo would likewiſe $\frac{x^2}{z^2} - 7\frac{y^2}{z^2} = 11$; which we have ſeen is impoſſible.

Ex. 2.—It is required to aſcertain the poſſibility or impoſſibility of the equation

$$x^2 - 13y^2 = 12$$

ſquares 1^2, 2^2, 3^2, 4^2, 5^2, 6^2 divided by 13
remainders 1, 4, 9, 3, 12, 10

And the ſame ſquares, divided by 12, give for
remainders 1, 4, 9, 4, 1, 0

alſo, $\frac{13}{12} = 1$ and remainder 1.

And here, ſince 12 is found in the upper ſeries, and 1 in the lower, the equation is ſolvible.

Note.—If the equation propoſed be of the form

$$x^2 - Ay^2 = -B,$$

we muſt employ, inſtead of the poſitive remainders ariſing from A, the negative remainders of the ſame, that is, taking the quotients in exceſs. And if the equation have the form

$$x^2 + Ay^2 = B,$$

then we muſt employ the negative remainders of B. Having thus given an idea of the method of judging of the poſſibility of every equation of the form $x^2 - Ay^2 = B$; and having alſo ſhewn how any indeterminate of the ſecond degree may be reduced to this form, it only remains to ſhew the method of ſolution of the above equation; or, which is ſtill a more general form, of the equation

$$x^2 - Ag^2 = Bz^2;$$

but in this, as in the other propoſitions, we can only indicate the method, without attempting to inveſtigate the rationale of the operation; as this would carry us much beyond our limits. Now it is ſhewn under the article Diophantine, that the ſolution of the equation $x^2 - y^2 = C z^2$ is always to be obtained; and in the following propoſition, with which we ſhall conclude this article, it will be ſeen that every equation of the form $x^2 - A y^2 = B z^2$, which is poſſible, may be transformed to another of the form $x'^2 - y'^2 = c z'^2$; and that x, y, and z, in the original equation, will be dependent upon thoſe of x', y', and z', in the transformed equation; and therefore theſe laſt being known, the former will be known alſo.

Prop. XIV.

To transform every poſſible equation of the form $x^2 - A y^2 = B$, to another dependent equation of the form $x'^2 - y'^2 = c z'^2$.

Ex. 1.—It is required to transform the equation $x^2 - 5 y^2 = 11 z^2$, to another of the form $x'^2 - y'^2 = c z'^2$.

Having firſt aſcertained the poſſibility of the equation by the foregoing propoſition, the transformation may be effected in the following manner.

Aſſume $x = n y - 11 y'$, and this ſubſtituted for x, gives

$$\left(\frac{n^2 - 5}{11}\right) y^2 - 2 n y y' + 11 y'^2 = z^2.$$

Take n, ſo that $n^2 - 5$ may be diviſible by 11; that is, let $n = 4$, and our equation becomes

$$y^2 - 8 y y' + 11 y'^2 = z^2; \text{ or}$$
$$(y - 4 y')^2 - 5 y'^2 = z^2$$

or, by making $y - 4 y' = x$, we have

$$x'^2 - 5 y'^2 = z^2; \text{ or,}$$
$$x'^2 - z^2 = 5 y'^2, \text{ as required,}$$

that is, the equation has been reduced from the form $x^2 - 5 y^2 = 11 z^2$, to another of the form $x'^2 - y'^2 = c z'^2$, or, at leaſt, to $x'^2 - z^2 = 5 y'^2$; which differs from the foregoing only in the letters.

And, by means of the values of x', y', and z, in this laſt, we readily arrive at thoſe of x, y, and z, in the one propoſition;

$$\text{for } x' = y - 4 y', \text{ or } y = x' + 4 y'$$
$$\text{and } x = n y - 11 y', \text{ or } x = 4 y - 11 y'$$

Now we have ſeen, under the article Diophantine, that the general values of x' and z, in equations of the form $x'^2 - z^2 = 5 y'^2$, are

$$\begin{cases} x' = p^2 + 5 q^2 \\ z = p^2 - 5 q^2 \\ y' = 2 p q \end{cases}$$

whence we have, for the general values of x, y, and z, in the equation propoſed,

$$x = 4 p^2 + 20 q^2 + 10 p q$$
$$y = p^2 + 5 q^2 + 8 p q$$
$$z = p^2 - 5 q^2$$

where p and q may be aſſumed any numbers at pleaſure. If $p = 3$, and $q = 1$, we have $x = 86$, $y = 38$, and $z = 4$; which numbers anſwer the required conditions; for

$$86^2 - 5 \,.\, 38^2 = 11 \,.\, 4^2;$$

and by giving different values to p and q, a variety of other integral values may be found for x, y, and z.

Note.—It may happen that the firſt transformation will not reduce the equation to the form required, in which caſe we muſt again transform this anew, and, by continuing the operation, the reduction to the final form will be ultimately effected.

Ex. 2.—Required the values of x, y, and z, in the equation

$$x^2 - 12 y^2 = 13 z^2.$$

Firſt, we have $x = n y - 13 y'$, and ſubſtituting for x we have

$$\left(\frac{n^2 - 12}{13}\right) y^2 - 2 n y y' + 13 y'^2 = z^2;$$

and here $n = 5$, whence the equation becomes

$$y^2 - 10 y y' + 13 y'^2 = z^2; \text{ or}$$
$$(y - 5 y')^2 - 12 y'^2 = z^2$$

Make now $y - 5 y' = x'$, and it becomes

$$x'^2 - z^2 = 12 y'^2$$

and the general values of x' and z in this equation, are

$$x' = 3 p^2 + 4 q^2, \; z = 3 p^2 - 4 q^2, \text{ and } y' = 2 p q.$$

Whence, by aſſuming $p = 2$, and $q = 1$, we have $x' = 16$, $z = 8$, and $y' = 4$; ſo that in the original equation, the values of x, y, and z, are as follow; *viz.*

$$\left.\begin{aligned} y &= x' + 5 y' = 36 \\ x &= 5 y - 12 y' = 132 \\ z &= z \qquad\quad\;\; = 8 \end{aligned}\right\} \text{ or, } \begin{cases} y = 9 \\ x = 33 \\ z = 2 \end{cases}$$

the latter values being formed by dividing the former by their greateſt common diviſor; and either of theſe ſets of numbers anſwer the required conditions; for,

$$132^2 - 12 \,.\, 36^2 = 13 \,.\, 8^2, \text{ and } 33^2 - 12 \,.\, 9^2 = 13 \,.\, 2^2;$$

and various other values may be obtained by changing the values of p and q.

We will now give one example in which the required reduction does not take place in the firſt transformation.

Ex. 3.—Required the values of x, y, and z, in the equation

$$x^2 - 5 y^2 = 19 z^2.$$

Aſſume, as before, $x = n y - 19 y'$: then the ſubſtitution of this value for x, gives

$$\left(\frac{n^2 - 5}{19}\right) y^2 - 2 n y y' + 19 y'^2 = z^2; \text{ in which } n = 10$$

$$\text{Whence } 5 y^2 - 10 y y' + 19 y'^2 = z^2, \text{ or}$$
$$25 y^2 - 50 y y' + 95 y'^2 = 5 z$$

$$\text{Making now, } 5 y - 10 y' = x'; \text{ we have}$$
$$x'^2 - 5 y'^2 = 5 z^2$$

and here, though we have not arrived at the form required, the laſt co-efficient is reduced from 19 to 5; and thus every ſucceſſive transformation will reduce the co-efficients, till we ultimately arrive at that of unity; but without purſuing this reduction farther in the preſent caſe, we are led to the ſolution in an eaſier manner: for we ſee immediately, that x' may be aſſumed $= 5$, $y' = 2$, and $z = 1$.

And from theſe we readily aſcertain thoſe of x, y, and z, in the propoſed equation; for

$$\begin{cases} y = \dfrac{x' + n y'}{5}; \text{ or } y = \dfrac{5 + 10 \,.\, 2}{5} = 5 \\ x = n y - 19 y'; \text{ or } x = 50 - 38 = 12 \\ z = 1 \qquad\qquad\;\; ; \text{ or } z = \end{cases}$$

which give $12^2 - 5 \,.\, 5^2 = 19 \,.\, 1^2$, as required.

We ſhall now conclude this article with a ſynopſis of indeterminate formulæ; the demonſtration and application of which the reader will find in Barlow's "Elementary Inveſtigation of the Properties of Numbers."

Synopſis of Indeterminate Formulæ.

Form. 1. Equation $ax - by = \pm c$

$$\begin{cases} \text{General value of } x = mb \pm cq \\ \qquad\qquad\qquad \text{of } y = ma \pm cp \end{cases}$$

in which expreſſions m is indeterminate, and the values of p and q reſult from the ſolution of the equation $ap - bq = \pm 1$.

Form. 2. Equation $ax + by = c$

$$\begin{cases} \text{General value of } x = cq - mb \\ \qquad\qquad\qquad\qquad y = ma - cp \end{cases}$$

$$\text{Number of ſolutions} = \frac{cq}{b} - \frac{cp}{a}$$

the quantities p and q being aſcertained as above, alſo m indeterminate.

Form. 3. Equation $ax + by + cz = d$

$$\begin{cases} \text{General value of } x = (d - cz)\,q - mb \\ \qquad\qquad\qquad\qquad y = ma - (d - cz)\,p \end{cases}$$

the quantities p and q being found as above, alſo m indeterminate, and z any integer $< \frac{d}{c}$.

Form. 4. Equation $x^2 - ay^2 = z^2$.

$$\begin{cases} \text{Gen. val. of } x = p^2 + aq^2 \\ \qquad\qquad\quad y = 2pq \\ \qquad\qquad\quad z = p^2 - aq^2 \end{cases}$$

in which expreſſions a is given, and p and q are indeterminates, that may be aſſumed at pleaſure.

Form. 5. Equation $x^2 + ay^2 = z^2$.

$$\begin{cases} \text{Gen. val. of } x = p^2 - aq^2 \\ \qquad\qquad\quad y = 2pq \\ \qquad\qquad\quad z = p^2 + aq^2 \end{cases}$$

a being given, and p and q indeterminates as above.

Form. 6. Equations $ax^2 + bxy + y^2 = z^2$.

$$\begin{cases} \text{Gen. val. of } x = 2pq + bq^2 \\ \qquad\qquad\quad y = p^2 - aq^2 \\ \qquad\qquad\quad z = p^2 + bpq + aq^2, \end{cases}$$

where p and q are indeterminates, and a and b given quantities.

Form. 7. Equation $ax^2 + bx = z^2$.

$$\begin{cases} \text{Gen. val. of } x = \dfrac{bq^2}{p^2 - aq^2} \\ \qquad\qquad\quad z = \dfrac{bpq}{p^2 - aq^2}, \end{cases}$$

where a and b are known quantities, and p and q indeterminates.

Form. 8. Equation $m^2x^2 + bx + c = z^2$.

$$\begin{cases} \text{Gen. val. of } x = \dfrac{p^2 - cq^2}{bq^2 - 2mpq} \\ \qquad\qquad\quad z = \dfrac{mp^2 + mcq^2 - bpq^2}{bq^2 - 2mpq}, \end{cases}$$

where m, b, and c are any given numbers, and p and q indeterminates.

Synopſis of Indeterminate Formulæ.

Form. 9. Equation $ax^2 + bx + m^2 = z^2$.

$$\begin{cases} \text{Gen. val. of } x = \dfrac{bq^2 - 2mpq}{p^2 - aq^2} \\ \qquad\qquad\quad z = \dfrac{mp^2 + amq^2 - bpq}{p^2 - aq^2}, \end{cases}$$

where m, a, and b are known; and p and q indeterminates.

Form. 10. Equation $x^2 - Ny^2 = \pm 1$.

$$\begin{cases} \text{Gen. val. of } x = \dfrac{(p + q\sqrt{N})^m + (p - q\sqrt{N})^m}{2} \\ \qquad\qquad\quad y = \dfrac{(p + q\sqrt{N})^m - (p - q\sqrt{N})^m}{2\sqrt{N}}. \end{cases}$$

where p and q ariſe from the equation $p^2 - Nq^2 = \pm 1$, and m is indeterminate; except that it muſt be even or odd, as the caſe requires. See Prop. IX.

Form. 11. Equation $x^2 - Ny^2 = \pm A$.

$$\begin{cases} \text{Gen. val. of } x = pm \pm Nqn \\ \qquad\qquad\quad y = pn \pm qm, \end{cases}$$

the values of m and n being formed from the equation $m^2 - Nn^2 = \pm A$, and p and q from the equation $p^2 - Nq^2 = \pm 1$.

Form. 12. Equation $ax^3 + bx^2 + cx + f^2 = z^2$.

$$\begin{cases} \text{Particular val. of } x = \dfrac{c^2 - 4bf^2}{4af^2}, \\ \text{Or,} \qquad\qquad\quad x = \dfrac{(8af^4 - 4bf^2c + c^3)\,8f^2}{(4bf^2 - c)^2}, \end{cases}$$

where all the quantities a, b, c, and f are given.

Form. 13. Equation $ax^4 + bx^3 + cx^2 + dx + f^2 = z^2$.

$$\left\{ \text{Partic. val. of } x = \frac{(8bf^4 - 4cdf^2 + d^3)\,8f^2}{16c^2f^4 - 64af^6 - 8cd^2f^2 + d^4}, \right.$$

where a, b, c, &c. are all known quantities.

Form. 14. Equation $m^2x^4 + bx^3 + cx^2 + dx + e = z^2$.

$$\left\{ \text{Partic. val. of } x = \frac{16c^2m^4 - 64em^6 - 8cb^2m^2 + b^4}{(8dm^4 - 4cbm^2 + b^3)\,8m^2}, \right.$$

where alſo m, b, c, &c. are all known quantities.

Form. 15. Equation $m^2x^4 + bx^3 + cx^2 + dx + f^2 = z^2$.

$$\begin{cases} \text{Particular val. of } x = \dfrac{d^2 \pm 8mf^3 - 4cf^2}{4bf^2 \mp 4mdf}, \\ \text{Or,} \qquad\qquad\quad x = \dfrac{4m^2d \pm 4mbf}{b^2 \mp 8m^3f - 4m^2c}. \end{cases}$$

In theſe expreſſions m, b, c, &c. are known quantities, and with regard to the ambiguous ſign, it muſt be obſerved, that when it is taken + in the numerator, it muſt be − in the denominator, and the contrary.

Form. 16. Equation $ax^3 + bx^2 + cx + f^3 = z^3$.

$$\left\{ \text{Particular val. of } x = \frac{(c^2 - 3bf^2)\,9f^3}{27af^6 - c^3}, \right.$$

a, b, c, &c. being known quantities.

Synopſis of Indeterminate Formulæ.

Form. 17. Equation $m^3 x^3 + b x^2 + c x + d = z^3$.

$$\left\{ \text{Particular val. of } x = \frac{b^3 - 27 d m^6}{(3 c m^3 - b^2) 9 m^3}, \right.$$

a, b, c, &c. being given quantities, as above.

Form. 18. Equation $m^3 x^3 + b x^2 + c x + f^3 = z^3$.

$$\left\{ \begin{array}{ll} \text{Particular val. of } x = & \dfrac{(c^2 - 3 b f^3) 9 f^3}{27 m^3 f^6 - c^3}, \\ \text{Or,} \qquad x = & \dfrac{b^3 - 27 f^3 m^6}{(3 c m^3 - b^2) 9 m^3}, \\ \text{Or,} \qquad x = & \dfrac{3 m f^2 - c}{b - 3 m f}, \end{array} \right.$$

where alſo m, b, c, &c. are known quantities.

Form. 19. Equation $x^2 + a x y + b y^2 = z^3$.

$$\left\{ \begin{array}{l} \text{General val. of } x = t^3 - b t u^2 - a b u^3 \\ y = 3 t^2 u + 3 a t u^2 + (a^2 - b) u^3 \\ z = t^2 + a t u + u^2, \end{array} \right.$$

where t and u may be aſſumed at pleaſure.

Form. 20. Equation $x^2 + b y^2 = z^3$.

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = t^3 - b t u^2 \\ y = 3 t^2 u - b u^3 \\ z = t^2 + u^2, \end{array} \right.$$

t and u being indeterminates, as above.

Form. 21. Equation $x^2 + b y^2 = z^4$.

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = t^4 - 6 b t^2 u^2 + b^2 u^4 \\ y = 4 t^3 u - 4 b t u^3 \\ z = t^2 + b u^2, \end{array} \right.$$

t and u being indeterminates, as above.

Form. 22. Equation $x^2 + b y^2 = z^m$.

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = t^m - \beta t^{m-2} u^2 b + \delta t^{m-4} u^4 b^2 - \text{\&c.} \\ y = \alpha t^{m-1} u - \gamma t^{m-3} u^3 b + \epsilon t^{m-5} u^5 b^2 \text{\&c.} \\ z = t^2 + b u^2, \end{array} \right.$$

where t and u are indeterminates, and 1, α, β, γ, δ, &c. the co-efficients of $(t + u)^m$.

Form. 23. Equation $x^3 + c y^3 = z^2$.

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = 4 t^4 - 4 c t u^3 \\ y = 8 t^3 u + c u^4 \\ z = t^3 + c u^3, \end{array} \right.$$

where t and u are indeterminates.

Form. 24. Equation $x^3 + a x^2 y + b x y^2 + c y^3 = z^2$.

$$\left\{ \text{Partic. val. of } t = - \frac{u^2 + 2 a u w + (a^2 - b) w^2}{2 w}. \right.$$

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = t^2 + 2 c u w + a c w^2 \\ y = 2 t u - 2 b u w - (a b - c) w^2, \end{array} \right.$$

where u and w are indeterminates, on which alſo depends the value of t

Indeterminate *Problem*, is that in which there are more unknown quantities than there are equations; and therefore from the principles of algebra the number of ſolutions is unlimited, unleſs ſome other condition enter, ſuch as requiring integral values of the unknown quantities, by which means the problem frequently admits of only a definite number of anſwers; as may be ſeen in the preceding article. In geometry a problem is always ſaid to be indeterminate, or unlimited, when there are not ſufficient data to limit its conſtruction.

INDEX, in *Anatomy*, the fore-finger.

Index, in *Arithmetic*, is the ſame with what is otherwiſe called the characteriſtic, or exponent of a logarithm.

The index is that which ſhews of how many places the abſolute number belonging to the logarithm conſiſts, and of what nature it is, whether an integer, or a fraction.

Thus, in this logarithm 2.521293, the number ſtanding on the left hand of the point is called the index; and becauſe it is 2, it ſhews you that the abſolute number anſwering to it conſiſts of three places; for it is always one more than the index, becauſe the index of 1 is 0; of 10 is 1; and of 100 is 2, &c. And, therefore, in thoſe ſmall tables of Briggs's Logarithms, where the index is omitted, it muſt be always ſupplied before you can work by them. If the abſolute number be a fraction, the index of the logarithm has a negative ſign, and is marked thus, $\bar{2}.562293$: which ſhews the correſponding number to be a decimal fraction of three places; *viz.* 1.365.

Mr. Townly has a peculiar way of noting theſe indices, when they expreſs fractions, now much in uſe, *viz.* by taking, inſtead of the true index, its arithmetical complement to 10; ſo that he would write the logarithm now mentioned thus: $\bar{8}.562293$.

How indices are to be added and ſubtracted, ſee under the article Logarithm.

Index, in *Muſic*, a character uſually placed at the end of each line to indicate the firſt note of the next line. The following is the character W, which the Italians term a *moſtra*, the Engliſh call it a *direct*.

Index *of a Book*, is that part annexed to a book, referring to the particular matters or paſſages therein contained.

Index *of a Globe*, is a little ſtyle fitted on to the north-pole, and turning round with it, pointing to certain diviſions in the hour-circle.

It is ſometimes alſo called *gnomon*. See Globe.

Index *of Relation*, in *Algebra*, the ſame with ſcale of relation. See Scale.

Index, or *Indice*, is alſo the denomination of a congregation at Rome, whoſe buſineſs is to examine books, and to put ſuch as they think fit to prohibit the reading and ſelling of, into an index. See Congregation.

Indices, or *Expurgatory Indices*, denote the name by which the catalogues of prohibited books are called; among which, however, there is this difference, that ſome are condemned purely and abſolutely, and others only *donec corrigantur*, till they be corrected.

Father Paul ſays, that Philip of Spain was the firſt who, by a law made in 1558, procured an index to be publiſhed of the books condemned by the inquiſition of Spain. Pope Paul IV. took the hint, and ordered the congregation of the holy office at Rome to print a ſecond in 1559. But Gretſer, (De Jure Prohib. lib. ii. cap. 19.) ſays, that the index of prohibited books was printed in Italy, by the papal authority, in 1548; and a larger one in 1552; and another larger in 1554. Pius IV. recommended the matter to the council of Trent; the fathers at Trent, after ſeveral debates not being able to agree, thought fit to refer the whole affair to the pope, who, with the advice of certain learned prelates, publiſhed an index of the prohibited books, and certain rules, by his letters, in form of a brief. The ſame Pius IV. in a bull of March 24, 1564, ſays, that the index was preſented to him by order of the ſynod, that it ſhould not be publiſhed before it was approved by him. It was accordingly publiſhed by him, with a ſtrict charge that it ſhould be received by all, and the rules prefixed to it obſerved. Clement VIII. enlarged and confirmed it, together with the rules, and commanded it to be publiſhed in 1595. This was called by the name of the Roman index. By the fourth rule, the common reading of the Holy Scriptures is forbid in theſe words. "Since it is plain by experience, that if the ſacred writings are permitted every where, and without difference to be read in the vulgar tongue, men, through their raſhneſs, will receive more harm than good; let the biſhop or inquiſitor determine, with the advice of the pariſh prieſt or confeſſor, to whom to permit the reading of the bible, tranſlated by Catholic authors in the vulgar tongue, according as they ſhall judge whether it be moſt likely that ſuch reading of the ſcripture may do harm, or tend to the increaſe of faith and piety. Let them alſo have the ſame power as to all other writings. But if any, without ſuch leave, ſhall preſume to read or have them, without firſt ſhewing the bible to the ordinaries, he ſhall not receive the abſolution of his ſins. And as to all bookſellers, who ſhall ſell the bibles tranſlated into the vulgar tongue, without ſuch leave, or by any other method ſhall publiſh them, let them forfeit the price of the books, and let the money be given to pious uſes by the biſhop; and let them be ſubject to other puniſhments; at the pleaſure of the ſaid biſhop, according to the nature of the offence. As to regulars, they ſhall not read or buy them, without leave firſt obtained from their prelates." The tenth rule enjoins ſeveral reſtrictive regulations concerning the printing and publication of books. Hardouin's Concil. tom. x. p. 207, &c.

In pope Clement's catalogue is an extraordinary kind of decree, that all the books of Catholic authors, written ſince the year 1515, which was the year immediately preceding that in which Luther began to declaim againſt indulgences, ſhould be corrected; not only by retrenching what is not conformable to the doctrine of Rome, but alſo by adding what may be judged proper by the correctors.

After this, the duke of Alva procured another to be printed at Antwerp in 1571, which was publiſhed by Francis Junius about the year 1586. There were two others publiſhed in 1584, and 1612, by the cardinals Quiroga and Sandoval, and ſeveral others by the inquiſitors and maſters of the ſacred palace. The moſt conſiderable of all the indices is that of Anthony a Sotomayor, ſupreme preſident and inquiſitor-general in the kingdom of Spain, which was made for all the ſtates ſubject to the king of Spain, and comprehends all the others. This was publiſhed, with the advice of the ſupreme ſenate of the general inquiſition, in 1640, and reprinted at Geneva in 1667. To this there were many rules prefixed; and to the Geneva edition was added the index of the decrees which were made by the maſter of the holy palace, by virtue of his office, or by the command of the holy congregation, or by the holy congregations for the indices and holy office, after the before-mentioned index of the council of Trent. The rules of the former indices are explained and confirmed by theſe; and the fifth rule, which enlarges the fourth of the index of Trent, prohibits not only all bibles in the vulgar tongue, comprehending all except thoſe that are Hebrew, Greek, Latin, Chaldee, Syriac, Ethiopic, Perſic, and Arabic; but all parts of them, either printed or manuſcript, with all ſummaries and abridgments in the vulgar language or tongue. Limborch's Hiſt. of the Inquiſition by Chandler, book ii. chap. 16.

Of the operation of theſe indices, the authors of the Encyclopædia obſerve, that there has been hardly any good book of piety or morality in their language which has not been proſcribed. Art. *Index.*

INDGEH, in *Geography*, a town of Aſiatic Turkey, in Caramania; 12 miles S.W. of Kaiſarieh.

Indgeh *Su*, a town of Aſiatic Turkey, in Natolia; 40 miles S.W. of Angura.

INDIA, an extenſive country of Aſia, which was divided by Ptolemy and the ancient geographers into "India extra Gangem" and "India intra Gangem," or the peninſula beyond the Ganges and that on this ſide of the Ganges, to which the appellation of India, according to its original etymology, as the country of the people called "Hindoos," properly belongs. (See Hindoostan.) India on this ſide of the Ganges was bounded, according to Ptolemy, on the W. by the Paropamiſus, Arachoſia, and Gedroſia; on the N. by mount Imaus; on the E. by the Ganges; and on the S. and partly on the W. by the Indian ſea. The gulf into which the Indus diſcharged itſelf was called "Canthi-Colpus," and an iſland in this gulf was named "Barace." The weſtern mouth of the Indus was denominated "Sagapa." Ptolemy enumerates ſeven mouths of this river under this and the following names; *viz.* "Oſtium Sinthum, Oreum, Chariphi, Saparages, Sabalaſſa, and Lonibare." To the Ganges Ptolemy aſſigns five mouths, *viz.* thoſe of "Polura, Oſtium Magnum, O. Chambericum, O. Pſeudo-ſtomum, and Antibole." The part of India, which was ſituated towards the weſt, was called "Indo-Scythia." India beyond the Ganges had the Ganges on the W., on the N. certain parts of Scythia and Serica; on the E. the country of the Sinæ; and to the S. the Indian ſea. This, however, is a vague name for wide and various, and till of late very much unknown, regions between Hindooſtan and China. The territory thus denominated is rich and extenſive, and includes the Birman empire, and the dominions of Pegu, Siam, Laos, Cambodia, Siampa, Cochinchina, Tonquin, and Malacca: which ſee reſpectively. See alſo Arracan, Asam, Ava, and Thibet. For an account of "Hither India," or "India intra Ganges," ſee Hindoostan and *Eaſt India* Company. For an elaborate account of the "Political Hiſtory of India, from the introduction of Mr. Pitt's bill, A. D. 1784, to the preſent date," ſee Mr. Malcolm's "Sketch." Lond. 1811, 8vo.

India, *Eaſt, Company, Coins, Silk,* &c. See Company, Coin, Silk, &c.

India, Sigismondo d', in *Biography*, a muſical compoſer, who was born at Palermo in Sicily, and flouriſhed about the year 1610. In 1611 he publiſhed at Venice two ſets of madrigals; and in 1627 a book of motetti, which did not go down the ſtream of oblivion unnoticed.

INDIAN, in a general ſenſe, denotes any thing belonging to the Indies, Eaſt or Weſt.

Indian *Arrow root*, in *Botany*. See Maranta.

Indian *Bay*, in *Geography*, a bay that lies on the W. ſide of Bonaviſta bay, in Newfoundland.

Indian *Bread*, in *Botany*. See Cassada.

Indian *Corn*. See Maize.

Indian *Corn-ears, Petrified*, in *Natural Hiſtory*. Many of the early writers on extraneous foſſils mention ears of Indian corn among their reliquia. Mr. James Parkinſon, in his Organic Remains, vol. i. p. 450, ſhews, that what Emanuel

Swedenborg figured as an ear of Indian corn, is the ſtem of an unknown plant, which, at pages 424 and 427, is ſaid to belong to the ſeries of vegetable remains incloſed in iron-ſtone nodules. See plate 14. fig. 4. of W. Martin's Pet. Derb.

Indian *Cove*, in *Geography*, a harbour on the E. coaſt of Indian iſland, in Duſky bay.

Indian *Creek*, a creek on the iſland of Antigua, a little to the weſt of Standfaſt point.—Alſo, a river of Virginia, which runs into the Ohio, N. lat. 40° 25′. W. long. 80° 40′.—Alſo, a river of Virginia, which runs into the Cheſapeak, N. lat. 37° 43′. W. long. 76° 27′.

Indian *Creſs*, in *Botany*. See Tropæolum.

Indian *Corn Falls*, in *Geography*, a cataract in the river St. Mary, about twenty miles from lake Superior. N. lat. 46° 22′. W. long. 84° 25′.

Indian *Fig*, in *Botany*. See Cactus.

Indian *Gem*, in *Mineralogy*. See Gem.

Indian *God-tree*, in *Botany*. See Ficus.

Indian *Head*, in *Geography*, a cape on the E. coaſt of New Holland, ſo called by captain Cook from the number of natives who appeared near it as he paſſed in May 1770. S. lat. 25° 3′. E. long. 123° 56′.

Indian *Iſland*, a ſmall iſland near the coaſt of North Carolina, at the mouth of Pamlico ſound. N. lat. 35° 23′. W. long. 76° 50′.—Alſo, an iſland on the S. part of Duſky bay, on the coaſt of New Zealand, about four miles in circumference, ſo called by captain Cook; about four miles from Pickerſgill harbour.

Indian *Ink*. See Ink.

Indian *Leaf*, *Malabathrum*, in *Botany*. See Tamalapatra.

Indian *Mallow*. See Sida.

Indian *Millet*. See Holcus.

Indian *Oak*. See Tectona.

Indian *Ocean*, in *Geography*. See Ocean.

Indian *Old Town*, a town of America, in Hancock county, ſtate of Maine, ſituated on an iſland in Penobſcot river, juſt above the Great Falls, and about ſixty miles below the Forks. Here are about 100 families of Roman Catholics, the remains of the Penobſcot tribe, and the only Indians who reſide in the diſtrict of Maine. They are in a thriving ſtate, having obtained from the Provincial congreſs a tract of land, 12 miles wide, interſected in the middle by the river, and veſted with a right of hunting and fiſhing as far as the mouth of Penobſcot bay extends. They have a decent church, and a prieſt who conducts their religious ſervice.

Indian *Reed* and *Shot*, in *Botany*. See Canna.

Indian *River*, in *Geography*, a river of Delaware, which runs into Rehobot bay, N. lat. 38° 40′. W. long. 75° 16′.—Alſo, a ſmall arm of the ſea, between Chandlin and Pleaſant river, in the diſtrict of Maine.—Alſo, a river on the E. coaſt of the peninſula of Eaſt Florida, riſing near the ſea-coaſt, and running from north to ſouth, and forming a kind of inland paſſage along the coaſt. It is alſo called Rio Ays. N. lat. 27° 30′. W. long. 80° 40′.—Alſo, a town in Suſſex county, Delaware, containing 1547 inhabitants.

Indian *Sound*, a gulf or bay on the S. coaſt of Patagonia, communicating with the Straits of Magellan by St. Jerome's channel.

Indian *Town*, a ſmall town of North Carolina, 52 miles from Edenton.

Indian *Town Point*, a cape on the eaſt coaſt of the iſland of Antigua. N. lat. 17° 15′. E. long. 61° 22′.

Indian *Wood*, called alſo *Jamaica* and *Campeachy Wood*, is taken out of the heart of a large tree growing plentifully in the iſles of Jamaica, Campeachy, &c. uſed in dyeing, its decoction being very red.

It has been obſerved, that putting ſome of this decoction into two bottles, and mixing a little powder of alum with the one, it will become of a very beautiful red, which will hold; the other in a day's time becoming yellow, though both bottles were ſtopped from the air alike; and that if a little of the ſame decoction be expoſed to the air, it will become as black as ink in the ſame ſpace of time. See Campeachy *Wood*, Brasil, and Logwood.

INDIANA, in *Geography*, a territory on the N.W. ſide of the Ohio, and lately formed a part of the N. W. territory. In January 1801, it was by act of congreſs erected into a temporary government, with powers and privileges ſimilar to other territorial governments. It lies between the Great Miami river E., the Miſſiſſippi W., the Ohio S., and the Illinois N. It is divided into the three following counties:

Counties.	Inhabitants.	Chief Towns.	Inhabitants.
Knox	2517	St. Vincennes	714
Randolph	1103	Kaſkakias	467
St. Clair	1255	Kakokia	719
Total	4875		

This territory has a fine ſoil, adapted to corn, wheat, rye, oats, cotton, hemp, tobacco, &c. The two weſtern counties of Randolph and St. Clair have lately petitioned congreſs to be annexed to the Upper Louiſiana, in the territorial government. On the N. W. bank of the Ohio, about twenty miles ſouthward of the mouth of the Wabaſh, N. lat. 37° 36′, is a remarkable cave, called the "Great Cave," which is one of the moſt ſurpriſing natural curioſities on the Ohio. The entrance is ſpacious and uniform; the dome is elliptical, and the uniformity continues to its termination in the hill. Morſe.

Indiana, a territory in Virginia, lying between Ohio river and the Laurel mountain, containing about 3½ millions of acres; of a form nearly triangular, and extending in length from the Pennſylvania line to the waters of the Little Kenhaway.

Indiana, a new county in the weſtern parts of Pennſylvania, which, with Weſtmoreland and Armſtrong, conſtitute a diſtrict for the choice of three repreſentatives.

INDIANE, a ſmall harbour in the iſland of Cape Breton.

INDIANS, the name given to the aborigines of America. Theſe people are ſcattered through the vaſt extent of the two prodigious continents, and divided into an infinite number of nations and tribes, differing from each other but little in their manners and cuſtoms. The Indians are tall and ſtraight in their limbs: their bodies are ſtrong, and adapted to endure much hardſhip. Their features are regular, but their countenances fierce; their hair long and lank, and the colour of their ſkins a reddiſh brown. Their only occupations are hunting and war; agriculture is left to the women, and for merchandize they have no taſte. They are hoſpitable, generous, and good-tempered; but to the enemies of their country they are implacable: no length of time can allay their reſentment, nor is any diſtance of place great enough to protect the object of their revenge. The Indians ſeem to have no juſt notion of a Supreme Being, though they maintain the exiſtence of ſuch a Being, eternal and incorruptible, who has power over all, to whom however they pay no worſhip: but they are exceedingly ſuperſtitious; and being deſirous to look into futurity, they encourage and ſupport a multitude of diviners, augurs, and magicians, upon whoſe deciſions and advice they rely in all matters that concern them, whether of health, war, or hunting. Liberty is the darling paſſion of the Indians; it is this which makes life ſupportable, and to this they are ready to ſacrifice every thing. Some tribes acknowledge a head or king, but he is reverenced as a father rather than feared as a monarch. He has no guards, no priſons, no officers of juſtice: in moſt caſes no other qualification is neceſſary for their chiefs, but age, experience, and ability in conducting their affairs. Every tranſaction is performed with much ceremony; and to fix the remembrance of them in their minds, they have belts of ſmall ſhells or beads of different colours, which have all a different meaning, according to their colour or arrangement. Theſe belts are carefully treaſured up in each town, and ſerve as the public records of the nation; and to theſe they occaſionally have recourſe when any diſputes happen between them and their neighbours.

When the ancients among the Indians have reſolved upon a war, they do not declare what nation they mean to attack, nor the time when the attack ſhall be made, in order that the enemy may be off his guard, and unprepared for defence: but the principal captain ſummons the youths of the town to which he belongs, the war-kettle is ſet on the fire, the war-ſongs and dances begin; the hatchet is ſent to all the villages of the ſame nation, and to all its allies; the fire catches, and the war-ſongs are heard in all parts. The prime qualities in an Indian war are vigilance and attention, to give and avoid ſurprize: likewiſe patience and ſtrength to endure the intolerable fatigues and hardſhips which always attend it. The fate of their priſoners is the moſt ſevere of all: during the greateſt part of their journey homewards they ſuffer no injury; but when they arrive at the territories of the conquering ſtate, or at thoſe of their allies, the people from every village meet them, and think that they ſhow their attachment to their friends by their barbarous treatment of the priſoners. Many writers have aſſerted that the Indians, even at the matureſt ſtage of their exiſtence, are only furniſhed with hair on their heads, and that the other parts of the body are always free from it. This, however, is not the truth, for, naturally, their bodies reſemble thoſe of the Europeans; but regarding the beard, &c. as deformities, they pluck out each hair by its root, in order to increaſe their beauty. The men of every Indian nation differ in dreſs from each other, excepting thoſe who trade with Europeans; theſe exchange their furs for blankets, ſhirts, and other apparel, which they wear as much for ornament as neceſſity. Thoſe among the men who wiſh to appear gayer than the reſt, pluck out the hair from their heads, except from a ſpot on the top of it, about the ſize of a crown piece, where it is permitted to grow to a conſiderable length: on this is faſtened a plume of feathers of various colours, with ſilver or ivory quills. The manner of cutting and ornamenting this part of the head diſtinguiſhes different nations from each other. They paint their faces red and black, and their whole bodies when they go to war. Young Indians, who are deſirous of excelling their companions in finery, ſlit the outward rim of both ears, at the ſame time that they take care not to ſeparate them entirely, but leave the place thus cut ſtill untouched at both extremities; around this ſpongy ſubſtance they twiſt braſs wire, till the weight draws the amputated rim into a bow of five or ſix inches in diameter, and drags it almoſt down to the ſhoulder. It is alſo a common cuſtom among them to bore their noſes, and wear in them pendants of different ſorts: ſea ſhells are much worn by thoſe of the interior, and are reckoned ornamental. Indians in general pay greater attention to their dreſs, and to the ornaments with which they decorate their perſons, than to the accommodation of their huts or tents. They conſtruct the latter in the following method: being provided with poles of a proper length, they faſten two of them acroſs near the ends with bands made of bark: having done this, they raiſe them up, and extend the bottom of each as wide as they purpoſe to make the area of the tent: they then erect others of an equal height, and fix them ſo as to ſupport the two principal ones: over the top they ſpread the ſkins of beaſts. Theſe tents have neither chimnies nor windows; there is only an aperture left in the middle of the roof, through which the ſmoke is diſcharged. They have ſkins alſo for beds, generally thoſe of the bear, which are placed in rows on the ground; and if the floor is not large enough to contain beds ſufficient for the accommodation of the whole family, a frame is erected a few feet from the ground, in which the younger part of it ſleep. As the habitations of the Indians are thus rude, their domeſtic utenſils are few in number, and plain in their formation. The tools with which they faſhion them are ſo awkward and defective, that it is not only impoſſible to form them with any degree of neatneſs, but the time required in the execution is ſo conſiderable, as to deter them from engaging in the manufacture of thoſe which are not abſolutely neceſſary. All the tribes are now poſſeſſed of knives, and ſteels to ſtrike fire with: theſe are regarded as eſſential to the common uſes of life, and the Indians uſually purchaſe them with ſlaves. Indians, by a ſurpriſing ſagacity, will croſs a foreſt or plain of the greateſt extent, and reach with the utmoſt exactneſs the place of their deſtination without any deviation from a direct line. Their memory is very tenacious, their belts of wampum preſerve the ſubſtance of treaties which they have concluded with the neighbouring tribes for ages back, to which they will appeal with as much readineſs and perſpicuity as Europeans can to their written records. Every nation pays great reſpect to the dictates of age. The advice of a father is regarded: but the deciſions of a grandfather create in the minds of the young an awe which they cannot withſtand: his words are conſidered and obeyed as oracles. The Indians are fond of gaming, and often ſtake their arms, their apparel, and every thing of which they are poſſeſſed: they are ſtrangers to all diſtinction of property, except in articles of domeſtic uſe, which every one conſiders as his own, and increaſes as circumſtances admit. They are extremely liberal to each other, and ſupply the exigencies of thoſe who belong to the ſame band with their ſuperfluities. Of the value of money the Indians, excepting thoſe who live near the European colonies, have no idea, but conſider it as a ſource of innumerable evils. They are equally indifferent to the productions of art. They are ignorant of the ſciences, and ſeem quite unacquainted with the firſt principles of aſtronomy, yet they contrive to divide the time in a rational and perſpicuous manner. They count their years by winters, or, as they expreſs themſelves, by their ſnows; and they divide the years by the moons; and on the firſt appearance of each new moon they repeat ſome joyful ſounds, ſtretching, at the ſame time, their hands towards it. Every month has with them a name expreſſive of its ſeaſon: that which anſwers to our March or April, they call the *worm* month, becauſe they obſerve that at this period the worms quit their retreats in the bark of trees, wood, &c. in which they have ſheltered themſelves during the winter: they have alſo the month or moon of flowers; the month of corn; the cold month; the ſnow month, &c. When the moon does not appear above the horizon, they ſay the moon is dead, and ſome call the three laſt days of each moon "naked days." They have no diviſions of weeks, but days they count by ſleeps; half days by pointing to the ſun at noon, and quarters by the riſing and ſetting of the ſun; to expreſs which, in their traditions they make uſe of hieroglyphics. Their ſole knowledge in aſtronomy conſiſts in being able to point out the polar ſtar, by which they regulate their courſe when they travel by night. They reckon diſtances from one place to another by days' journies, each being about 20 miles. They have no knowledge of arithmetic, and though they are able to count to any number, figures and letters appear to carry with them ſome hidden myſtery, and much above their comprehenſion. Every ſeparate body of Indians is divided into bands or tribes, and forms a little community within the nation to which it belongs. As the nation has ſome particular ſymbol by which it is diſtinguiſhed from others, ſo each tribe has a badge from which it is denominated, as that of the eagle, the panther, the tiger, the buffalo, &c. Throughout every nation they particularize themſelves in the ſame manner, and the meaneſt perſon among them will remember his lineal deſcent, and diſtinguiſh himſelf by his reſpective family. Every band has a chief, who is termed the Great Warrior, and who is elected for his warlike qualifications; beſides this there is another who enjoys a pre-eminence as his hereditary right, and has the more immediate management of their civil affairs. When the chiefs are convened on any public buſineſs, they always conclude with a feaſt, at which feſtivity and cheerfulneſs know no limits. Dancing is a favourite exerciſe among the Indians, they never meet on any occaſion but this makes a part of the entertainment; and when they are not engaged in war or hunting, the youth of both ſexes amuſe themſelves in this manner every evening. The Indians have ſeveral kinds of dances which they uſe on different occaſions, as the pipe or calumet dance, the war dance, the marriage dance, and the dance of the ſacrifice. The movements in every one of theſe are diſſimilar, though it is impoſſible to give ſuch a deſcription of them as will convey to an European a juſt idea of the diſtinctions. Hunting is their principal occupation; they are trained to it from their youth, and it is an exerciſe which is eſteemed no leſs honourable than neceſſary towards their ſubſiſtence. A dextrous hunter is held nearly in as high eſtimation as a diſtinguiſhed warrior. Scarcely any device which the ingenuity of man has diſcovered for enſnaring or deſtroying thoſe animals that ſupply them with food, or whoſe ſkins are valuable to Europeans, is unknown to them. Every hunter prepares himſelf by faſting during ſeveral days: the reaſon they give for this is, that faſting enables them to dream freely, and in their dreams they are informed where they ſhall find the greateſt plenty of game; it is thought alſo to avert the diſpleaſure of evil ſpirits, and induce them to be propitious. They ſeem to have ſome notion of a future ſtate of exiſtence, and ſuppoſe that their employments there will reſemble thoſe in which they are engaged here, without the labour and difficulty annexed to them in this period of exiſtence. Among thoſe who have prieſts, theſe prieſts are their phyſicians and their conjurors: they cure their wounds and diſeaſes, interpret their dreams, give them charms which ſhall render them ſuperior to external danger, and ſatisfy their curioſity with regard to future events. The Indian is ſubject to but very few diſeaſes; the moſt fatal and deſtructive is the ſmall-pox, which to them has been the moſt terrible of all peſtilences: this is not, however, continual in their country, as it is in other nations; frequently there are intervals of many years in which it is never heard of; but when it prevails, towns and villages are thinned of their inhabitants. An Indian is ſaid to meet death, when it approaches him in his hut, with the ſame reſolution with which he has often faced it in the field. If he is a chief, and has a family, he makes a kind of funeral oration, which he concludes by giving to his children neceſſary advice for the regulation of their conduct. He then takes leave of his friends, and iſſues out orders for the preparation of a feaſt, which is deſigned to regale thoſe of his tribe that come to pronounce his eulogium. After the laſt ſtruggle the body is dreſſed in the uſual habiliments; the face is painted, and it is placed in a ſitting poſture on a mat in the middle of the hut, with his weapons by his ſide. His relations being ſeated round, each harangues the deceaſed body, in turn, and, if he happen to have been a great warrior, recounts his heroic actions. After this, the body is carried to the burying place, where it is interred with other ceremonies. Such are the general characteriſtics of the Indians; the peculiarities of each tribe will be found in other parts of the dictionary. The amount of Indian population cannot be preciſely aſcertained. The newly diſcovered iſlands in the South ſea, and part of the N. W. coaſt, are probably the moſt populous; as they have ſuffered leſs by invaders. The beſt informed writers have conjectured the number of aboriginal Indians in America to be under 2½ millions. Since the diſcovery of America, the decreaſe, in conſequence of labour and oppreſſion, famine and peſtilence, has been aſtoniſhing. A liſt of Indian tribes, in Imlay's Hiſtory of Kentucky, makes the aggregate number leſs than 60,000 of thoſe who inhabit the country, from the gulf of Mexico on both ſides of the Miſſiſippi to the gulf of St. Lawrence, and as far weſt as the country has been generally explored, that is, to the head water of the Miſſiſippi, and from thence a good way up the Miſſouri, and between that river and Santa Fé. The population of the Indian nations in the ſouthern parts of the United States is given differently from Mr. Imlay's ſtatement by Mr. Purcell, who reſided among them in 1780, as follows:

	Gun men.	Total.
Muſcogees, commonly called Creeks	5860	17,280
Chactaws	4131	13,425
Chickaſaws	575	2290
Cherokees	2800	8550
Catabaws	150	400
	13,516	42,033

The above red nations have ſomewhat increaſed ſince the general peace eſtabliſhed among them in 1777. The whites incorporated among them are few in number, and lead a vagabond life, connecting themſelves with one tribe after another. The increaſe of population is conſiderably checked by the uſe of ſpirituous liquors, and by a certain complaint introduced among them by the whites. In the northern diſtrict of North America, Mr. Hutchins, in 1778, eſtimated the Indians N. of the Ohio, and E. of the Miſſiſippi, at 13,800, and thoſe weſtward of lake Superior and the Miſſiſippi, at 10,000.

INDICATION, in *Phyſic*, ſignifies the pointing out or diſcovering what is fit to be done, and what means applied in any caſe, from a knowledge of the nature of the diſeaſe, and the virtue of medicines.

Indications are of four kinds: *preſervative*, or *prophylactic*, which direct how to cut off the cauſe of an approaching diſeaſe; *curative*, which ſhew how to remove a diſeaſe actually formed; *palliative*, which direct how to leſſen its effects, or take off ſome of its ſymptoms, before it can be wholly removed; and *vital*, which relate to the ſtrength of the body.

That part of phyſic which treats of indications is called *ſemeiotice*.

INDICATIVE, in *Grammar*, the firſt mood or manner of conjugating verbs, ſhewing either the time preſent, paſt, or future, and aſſerting what we think certain; and, therefore, ſometimes called the *declarative* mood.

I love is the preſent tenſe; *I loved*, the paſt; and *I will love* is the future of the indicative mood.

INDICATIVE *Column*. See COLUMN.

INDICATOR, in *Anatomy*, extenſor or abductor indicis, cubito-ſus-ouguien; a muſcle of the fore-finger, ſituated on the dorſal ſurface of the fore-arm. It is a ſlender muſcle, of an elongated figure, extended from the back of the ulna to the fore-finger. It ariſes, by ſhort aponeurotic fibres, from the poſterior ſurface of the ulna, beginning about the middle of the bone, and having its attachment extended towards the wriſt; and in a ſlight degree from the interoſſeous ligament. It is ſlender and pointed at its origin, grows gradually larger, and then diminiſhes again and forms a ſmall flattened tendon. From its origin at the middle of the ulna, it paſſes obliquely to the carpal end of the radius, and is confined at the ſurface of that bone in a fibrous ſheath common to it with the extenſor communis, to which it is here attached by means of the ſynovial membrane which lines the ſheath. Quitting the ſheath, it runs along the back of the hand, on the radial ſide of the tendon, which the fore-finger receives from the extenſor communis: theſe two approach each other, and are united at the articulation of the finger to the metacarpus. The common tendon paſſes over the back of the firſt joint of the fore-finger, over the firſt phalanx, and then divides into three portions, which terminate like thoſe of the extenſor digitorum communis: it correſponds to them alſo in every other particular. See EXTENSOR.

The poſterior ſurface of this muſcle is covered by the extenſor carpi ulnaris, the extenſor proprius auricularis, and extenſor communis digitorum, and by the integuments. Its anterior ſurface is in contact with the ulna, interoſſeous ligament, radius, carpus, interoſſeous muſcle of the ſecond interval, metacarpus, ſynovial membranes of the digital articulations, and the phalanges. The radial edge is in contact for a conſiderable ſpace with the extenſor tertii internodii pollicis; the ulnar edge is attached to a ridge of the ulna. It will extend the three phalanges of the fore-finger, and move it towards the ulnar edge of the hand, as in pointing to an object. It will extend the wriſt, and aſſiſt in the ſupination of the radius.

INDICAVIT, in *Law*, a writ or prohibition that lies for a patron of a church, whoſe clerk is ſued in the ſpiritual court by another clerk for tithes, which do amount to a fourth part of the profits of the advowſon; then the ſuit belongs to the king's court, by the ſtat. Weſt. 2. cap. 5. And the patron of the defendant being likely to be prejudiced in his church and advowſon, if the plaintiff recovers in the ſpiritual court, hath this means to remove it to the king's court. Reg. Orig. 35. Old Nat. Br. 31.

INDICIS EXTENSOR, in *Anatomy*. See INDICATOR.

———— *Semi-interoſſeus*. See ABDUCTOR.

INDICTION, ſignifies the convoking of an eccleſiaſtical aſſembly; as a ſynod, or council, or even a diet.

INDICTION is applied to the ſeveral ſeſſions of the ſame councils.

Hence it is, that at the end of the ſeſſions of the council of Trent, the decree by which the council appoints the day of the future ſeſſion, is called the indiction of that ſeſſion.

INDICTION, in *Chronology*, a term uſed for a kind of epocha, or manner of counting time among the Romans; containing a cycle or revolution of fifteen years, which, when expired, begins anew, and goes round again without intermiſſion.

This method of computation has no dependence on the heavenly motions. Petavius ſays, there is nothing in chronology leſs known than the Roman indiction; he means, than its original and commencement. It is the general opinion, that it was inſtituted in the time of Conſtantine, about the year 312; but this is a mere gueſs. There were indictions in the time of the emperor Conſtantius, as appears from the Theodoſian Code. The learned hold, that indictions were originally no other than certain annual taxes, the tariffs whereof were publiſhed every year; but why they were ſo called, why confined to a cycle of fifteen years, when, and on what occaſion, inſtituted, is not known.

We find three kinds of indictions mentioned in authors; the indiction of Conſtantinople, beginning on the firſt of September; the Imperial, or Cæſarean indiction, on the fourteenth of September; and the Roman or Papal indiction, which is that uſed in the pope's bulls, and which begins on the firſt of January.

The popes have dated their acts by the year of the indiction, which was fixed to the firſt of January, A. D. 313, ever ſince Charlemagne made them ſovereign; before which time they dated them by the years of the emperors.

At the time of the reformation of the calendar, the year 1582 was reckoned the tenth year of the indiction; ſo that beginning to reckon hence, and dividing the number of years elapſed between that time and this by 15, the remainder, with the addition of 10, will be the year of indiction, correſponding to the year of our Lord 1811. The indiction may alſo be found by adding 3 to the year of our Lord, and dividing the ſum by 15, the remainder is then the year of the indiction: if there be no remainder the indiction is 15. In either of theſe ways the year of indiction for 1811 is 14.

The word indiction comes from *indictio*, which ſignifies *eſtabliſhment*, *order*, or *denunciation*. The time of the indiction, among the Romans, was that wherein the people were ſummoned to pay a certain tribute; and it is for this reaſon, that the imperial indiction began towards the end of September; becauſe the harveſt being then got in, it was ſuppoſed the people could more eaſily pay their tax.

INDICTIVE, INDICTIVUS, an epithet given to certain feaſt-days appointed by the Roman magiſtrates, *viz.* the conſul, or prætor.

INDICTMENT, derived from the French *enditer*, *indicare*, or, according to M. Lambard, from ενδεικνυμι, *I charge*, *I inform againſt*, in *Law*, a bill or declaration, of complaint, drawn up in form of law, for the benefit of the commonwealth: exhibited as an accuſation of one for ſome offence, criminal or penal, and preferred to a grand jury, and by their verdict found to be true, and preſented before a judge or officer, who has power to puniſh or certify the ſame offence.

INDICTMENT, in *Common Law*, ſignifies as much as *accuſatio* among the civilians; though in ſome points it differs. See ACCUSATION.

Lambard ſays, an indictment is an accuſation at the ſuit of the king, by the oaths of twelve men of the ſame county where the offence was committed; returned to inquire of all offences in general in the county, determinable by the court into which they are returned, and their finding a bill brought before them to be true. But when ſuch accuſation is found by a grand jury, without any bill brought before them, and afterward reduced to a formed indictment, it is called a preſentment; and when it is found by jurors returned to enquire of that particular offence only, which is indicted, it is properly called an inquiſition.

Although a bill of indictment may be preferred to a grand jury upon oath, they are not bound to find the bill, if they find cauſe to the contrary; and though a bill of indictment be brought to them without oath made, they may find the bill if they ſee cauſe. But it is not uſual to prefer a bill unto them before oath be firſt made in court, that the evidence they are to give unto the grand inqueſt to prove the bill is true.

The grand jury (ſee Jury) are to find the whole of a bill, or to reject it; and not to find it ſpecially in part, &c. If they are ſatisfied of the truth of the accuſation, they then indorſe upon the bill of indictment "a true bill," anciently *billa vera*. But to find a bill, there muſt at leaſt twelve of the jury agree. The indictment, when ſo found, is publicly delivered into court.

As indictments are purely for the good and quiet of the commonwealth, they are to be preferred for criminal, not civil matters. They are uſed in caſes of high treaſon, and petit treaſon, felony, and treſpaſſes of all kinds, and in all pleas of the crown; though they cannot be uſed for injuries of a private nature, that neither concern the king nor the public; and therefore all indictments ought to be brought for offences committed againſt the common law, or againſt ſtatutes; and not for every ſlight miſdemeanor. A perſon cannot be indicted of ſuſpicion of felony, but of the very crime itſelf; and then if he be not in cuſtody, the ſheriff is commanded to attach his body by a capias, &c. A perſon indicted for felony may have counſel allowed to ſpeak for him, as to matter of law only: but ſuch as are indicted for treaſon may have a copy of their indictment before trial, in order to adviſe with counſel; and ſuch indictments are to be found within three years after the offence committed, unleſs the treaſon be directly againſt the king's perſon. (7 and 8 W. III. cap. 3. which is extended to trials on impeachments by 28 Geo. II. cap. 30.) Perſons indicted of treaſon muſt be by the oaths of two witneſſes; but in other caſes one witneſs is ſufficient. The priſoner, in this caſe, ſhall alſo have a copy of the indictment, but not the names of the witneſſes, five days at leaſt before the trial, *i. e.* upon the true conſtruction of the act 7 W. III. cap. 3. before his arraignment; he ſhall alſo have a copy of the panel of jurors two days before his trial; and he ſhall have the ſame compulſive proceſs to bring in his witneſſes for him, as was uſual to compel their appearance againſt him. By 7 Ann. cap. 21. every perſon indicted for high treaſon, or miſpriſion of treaſon, ſhall not only have a copy of the indictment, but a liſt of all the witneſſes to be produced, and of the jurors impanelled, with their profeſſions and places of abode, delivered to him ten days before the trial, and in the preſence of two witneſſes. But this laſt act, ſo far as it affected indictments for the inferior ſpecies of high treaſon, reſpecting the coin and royal ſeals, is repealed by the ſtatute 6 Geo. III. cap. 53. But no perſon indicted for felony is, or (as the law ſtands) can be, entitled to ſuch copies, before the time of his trial.

Indictments muſt be certain in every point, and charge ſome particular offence; alſo goods ſtolen muſt be particularly ſet down, and the offence laid poſitively, and not by way of recital. There muſt alſo be expreſſed the Chriſtian name, ſurname, and addition of the offender, with the day, year, and place in which the offence was committed, as alſo the nature of the offence. (1 Hen. V. cap. 5.) In an indictment for murder, the length, depth, or other dimenſions of the wound, muſt be expreſſed, that a judgment may be formed whether it was mortal; and in this caſe, the time of the death muſt be laid within a year and a day after the mortal ſtroke was given. (See Appeal.) And in felony, the value of the things ſtolen is to be particularly mentioned, in order that it may appear whether the offender has been guilty of grand or petit larciny. A miſtake in ſpelling the defendant's ſurname is not a ſufficient cauſe for abating the indictment, provided it ſounds like it. If a word of conſequence be omitted in an indictment, it renders the whole naught; but the caſe is not the ſame where a word of form is omitted, or where there is an omiſſion of a ſynonymous word, if the ſenſe is not injured. In ſome crimes particular words of art muſt be uſed, which are ſo appropriated by the law to expreſs the preciſe idea which it entertains of the offence, that no other words, however ſynonymous they may ſeem, are capable of doing it. Thus, in treaſon, the facts muſt be laid to be done "treaſonably, and againſt his allegiance;" anciently, *proditorie et contra ligeantiæ ſuæ debitum*;" elſe the indictment is void. In indictments for murder, it is neceſſary to ſay that the party indicted "murdered," not "killed" or "ſlew" the other; which, till the late ſtatute, was expreſſed in Latin by the word "*murdravit*." In all indictments for felonies, the adverb "feloniouſly, *felonicè*," muſt be uſed; and for burglaries alſo "*burglariter*," or in Engliſh, "burglariouſly;" and all theſe to aſcertain the intent. In rapes the word "*rapuit*," or "raviſhed," is neceſſary, and muſt not be expreſſed by any periphraſis; in order to render the crime certain. So alſo in larcinies, the words "*felonicè cepit et aſportavit*," "feloniouſly took and carried away," are neceſſary to every indictment; for theſe only can expreſs the very offence. In caſe one part of an indictment is inconſiſtent with another part of it, the indictment becomes void; though where the ſenſe is plain, the court will diſpenſe with a ſmall inconſiſtency. Indictments are amendable the ſame term they are brought into court, but not afterwards; and in criminal proſecutions, the amendment muſt be only ſuch as is permitted by the common law. Indictments for crimes committed, ought to be laid in the county where they were done; for otherwiſe, upon pleading the general iſſue not guilty, if it appears that the offence was committed in another county or place different from that in the indictment, the defendant will be acquitted. Yet if larciny be committed in any one county, and the goods carried into another, the offender may be indicted in either for the offence is complete in both. (1 Hal. P.C. 507.) Or, he may be indicted in England for larciny in Scotland, and carrying the goods with him into England, or *vice verſa*; or for receiving in one part of the united kingdoms goods that have been ſtolen in another. (Stat. Geo. III. c. 31.) But for robbery, burglary, and the like, he can only be indicted where the fact was actually committed; for though the carrying away and keeping of the goods is a continuation of the original taking, and is therefore larciny in the ſecond county, yet it is not a robbery or burglary in that juriſdiction. And if a perſon be indicted in one *county* for larciny of goods originally taken in another, and be thereof convicted or ſtands mute, he ſhall not be admitted to his clergy; provided the original taking be attended with ſuch circumſtances, as would have ouſted him of his clergy by virtue of any ſtatute made previous to the year 1691. (Stat. 25 Hen. VIII. 3 W. and M. c. 9.

An offender is ſubject to indictment for a felony committed againſt a perſon unknown; yet ſomebody muſt be proved to be the proprietor upon the trial, or elſe the property will be preſumed to be in the priſoner, he having pleaded not guilty. An indictment being at the king's ſuit, the proſecutor is a good witneſs to prove the charge contained in it; and no damage can be given to the party aggrieved, except it be particularly grounded on ſome ſtatute. Indictments before juſtices of the peace may be removed by certiorari into the king's bench.

A bill of indictment is ſaid to be an accuſation, becauſe the jury, who inquire of the offence, do not receive it till the party that offered the bill, appearing, ſubſcribes his name, and offers his oath for the truth of it.

It is always at the ſuit of the king, and differs from an accuſation in this, that the preferrer is no way tied to the proof thereof upon any penalty if it be not proved, except there appears a conſpiracy. But if any one prefer an indictment to the grand jury for any criminal offence, without probable cauſe, and the bill is not found, or the party is acquitted, action lies for a malicious proſecution. In order to which it is neceſſary that the plaintiff ſhould obtain a copy of the record of his indictment and acquittal; but in proſecutions for felony, it is uſual to deny a copy of the indictment, where there is any the leaſt probable cauſe to found ſuch proſecution upon. But an action for a malicious proſecution may be founded on ſuch an indictment whereon no acquittal can be; as if it be rejected by the grand jury, or be *coram non judice*, or be inſufficiently drawn.

Indictments, *Demurrer to*. See Demurrer.

INDICTOR, in *Law*, he that indicteth another for an offence: and *indictee* is the party who is indicted. 1 Ed. III. cap. 11. 21 Jac. I. cap. 8.

INDICUM. In the writings of the ancients we find this word very frequently uſed, as the name of a blue colour, or pigment uſed in dyeing, and imported to Rome, Greece, and other parts of the world, from the Eaſt Indies. The greater number of writers make this the ſame with our indigo, or anil feculæ; and ſome ſay it was the ſame with our woad; but the former opinion ſeems moſt probable.

This ſubſtance, which the Greeks call indicum, the Arabian writers, Avicenna, Serapion, and others, have called *nil;* though the ſame word is alſo ſometimes uſed by them for the pigment made from woad. See Indigofera.

Indicum *Folium*. See Folium and Tamalapatra.

INDICUS Calmus, in *Natural Hiſtory*, is a foſſil coralline body, ſuppoſed formerly to repreſent ſome ſpecies of reed, beſet with ſtars on the ſurface.

Indicus *Cocculus*. See Cocculus.

Indicus *Color*, a term uſed by ſeveral of the ancient writers to expreſs black. The generality of the Greek and Roman phyſicians of old times have called the black lignum aloes, *agallochum indicum;* and the only black kind of myrobalan they were acquainted with, was in the ſame manner called the indicum; not that theſe were ſuppoſed peculiarly the product of the Indies, in diſtinction from the paler lignum aloes, or the other myrobalan; but that they were of that colour which they called indicus color.

Indicus *coſtus*. See Costus.

INDIES, East, in *Geography*, comprehends that vaſt tract of country, which is ſituated in the ſouth of Tartary, between Perſia and China, as well as the iſlands in the Eaſt Indian ſea, ſuch as Borneo, Sumatra, Ceylon, Java, the Maldives, Celebes, Moluccas, Philippines, &c. See India and Hindoostan, and each iſland ſeparately.

Indies, *Weſt*, includes iſlands of the Atlantic, which extend from the weſt of Florida, in a curve, to the coaſt of Surinam, in South America, from W. long. 58° 20′ to 85° 30′, and from N. lat. 10° to 27° 50′; Cuba being made the weſterly boundary, and the Bahamas the moſt northerly; and fixing the eaſterly point at the iſland of Barbadoes, and the ſoutherly at Trinidad. The name was given by Columbus, and has not been unfrequently applied to the whole of America. See each iſland ſeparately deſcribed.

INDIGENOUS, of *indigena*, denotes a native of a country; or that which was originally born or produced in the country where it is found. In this ſenſe, particular ſpecies of animals and plants are ſaid to be indigenous in the country where they are native, in oppoſition to exotic.

INDIGESTION, in *Medicine*, in the acceptation in which we employ the term, implies not only the imperfect performance of the act of digeſtion, but alſo an impaired condition of the functions of the ſtomach and chylopoetic viſcera in general.

In uſing the term *indigeſtion* in this extenſive ſenſe, we follow the example of Dr. Cullen, who has comprehended, under the head of *Dyſpepſia* (from δυς, *ill*, and πεπτειν, *to digeſt*), a great variety of ſymptoms, which other noſologiſts have conſidered as diſtinct diſeaſes, and deſcribed under various appellations, but which, he is of opinion, are all referrible to one common cauſe, an imbecility, or loſs of tone in the ſtomach. (See Cullen, Noſol. Method. Gen. xlv. and Firſt Lines, § 1190, and 1193). Among the ſymptoms juſt alluded to, which ſtand as diſtinct genera in other noſological ſyſtems, are *Anorexia*, or *loſs of appetite; Cardialgia*, or *heart-burn; Gaſtrodynia*, or *ſtomach colic; Flatulentia*, or *flatulence; Nauſea; Vomitus*, *Soda*, &c. (See the Noſol. Syſtems of Sauvages, Vogel, and Linnæus.) To the ſame diſordered condition of the digeſtive organs, when it is ſympathetic of, or combined with other complaints, Dr. Cullen likewiſe referred many of thoſe undefined affections, which have been confuſedly claſſed together under the general title of *nervous diſeaſes*, or under that of *chronic weakneſs*. From the great importance of the ſtomach in the animal economy, in which it is, as it were, the laboratory of health, and from its ſympathetic relation to every other important organ in the body, it is obvious that every derangement to which it is expoſed muſt occaſion ſome correſponding derangement in other parts of the ſyſtem, and that it muſt ſuffer, in its turn, whenever any diſtant organ is much indiſpoſed; and hence, that indigeſtion will moſt frequently be accompanied with various adventitious ſymptoms, and that it will be of two kinds, idiopathic and ſympathetic, according as the ſtomach itſelf, or ſome other organ, is the ſeat of the primary diſorder. It is of the idiopathic indigeſtion, however, that we particularly treat at preſent.

The ſymptoms which characterize idiopathic *dyſpepſia*, are an irregular, but commonly deficient appetite, with occaſional ſqueamiſhneſs, ſometimes actual vomiting;—a ſenſe of load and diſtention of the ſtomach after meals, followed by eructations of air, or of ſolid or fluid matter, of various qualities, acid, pungent, nidorous, or inſipid;—heartburn, and pains in the region of the ſtomach. Some or all of theſe ſymptoms occur at different times or in different individuals, and are commonly combined with irregularity of the bowels, which are moſt frequently coſtive, but ſometimes lax, or in each of theſe ſtates by turns. The mouth and throat are uſually dry, eſpecially in the morning, and the tongue is at the ſame time furred, and of a white or yellow colour, and there is a diſagreeable taſte on the palate.

Theſe are the direct indications of a deranged condition of the ſtomach itſelf, and the conſequent irritation of ill-digeſted aliment. The ſenſe of load is occaſioned by the remora of the food in its undigeſted ſtate, and that of diſtention by the evolution of air, which is probably occaſioned by the ſpontaneous decompoſition or fermentation of the alimentary matter, and is relieved by eructation and the diſcharge of flatus. The irritation of the acid or acrid crudities upon the coats of the ſtomach, eſpecially about the upper orifice, excites the ſenſation of heart-burn, and occaſional ſpaſmodic and inverted actions of the ſtomach and gullet, by which eructations are produced, as well as ſpaſmodic contraction of the muſcular parts of the ſtomach, which is accompanied by pain or gaſtrodynia: over-diſtention of the coats of the ſtomach, by the flatus, is likewiſe productive of pain.

But in addition to theſe morbid ſenſations and phenomena in the ſtomach itſelf, an infinite variety of ſymptoms occur, in different inſtances, indicating the ſympathetic affection of the conſtitution at large, or of particular organs. Theſe have commonly been called *nervous* ſymptoms, inaſmuch as they have originated merely from a ſympathy of parts, independently of any diſordered ſtate of the circulation, or of any morbid change in the ſtructure of the ſuffering organs; and they are often more diſtreſſing than the primary ſymptoms belonging to the affection of the ſtomach. Among the ſymptoms to which we allude, are languor, ſluggiſhneſs, and indiſpoſition to exertion, either mental or corporeal, but eſpecially the latter; drowſineſs, particularly after meals or ſlight exerciſe; giddineſs, noiſe in the ears, occaſional dimneſs of ſight, or a ſenſe of objects floating before the eyes, with head-ache under various forms, moſt frequently affecting the forehead and temples, ſometimes the crown and the *occiput;* ſevere flying pains; palpitations of the heart, or intermiſſions in its pulſation, with conſiderable variations in the ſtate of the pulſe; total reſtleſſneſs, or unrefreſhing ſleep during the night, with frightful dreams, the *incubus*, or night-mare, &c.; temporary abſence of mind, impaired memory, unuſual timidity and deſpondency; and, in ſhort, all the train of complaints which belong to *hypochondriaſis* and *hyſteria* in the conſtitutions in which they are liable reſpectively to occur. See theſe articles.

The experiments of modern phyſiologiſts have ſhewn that the proceſs of digeſtion is principally effected by means of the fluids of the ſtomach, which poſſeſs a ſolvent power over the ſubſtances uſed as aliment; and that it is not a proceſs of concoction, putrefaction, attrition, or fermentation, as was anciently ſuppoſed. (See DIGESTION.) It would ſeem, therefore, that the eſſential cauſe of idiopathic dyſpepſia conſiſts in a change in the quantity or quality of this gaſtric fluid, or ſolvent, originating from an impaired condition of the ſecretory function of the ſtomach. This, however, can perhaps only be aſcribed to the deficiency of its tone and vigour as a muſcular organ. Dr. Cullen juſtly remarks, that, as the peculiar nature of the digeſtive fluid, the changes which it may undergo, and the cauſes by which it may be changed, are very little known to us, we cannot found a practical doctrine upon any ſuppoſition reſpecting it; but as, at the ſame time, the imbecility of the ſtomach, either as the cauſe or the effect of the change in the digeſtive fluid, ſeems always to be preſent, and to have a great ſhare in occaſioning the ſymptoms of indigeſtion, we may ſtill conſider the imbecility of the ſtomach as the proximate and almoſt ſole cauſe of *dyſpepſia*. He obſerves, too, that this view of the ſubject is the more admiſſible, as it appears to be fully and clearly applicable to the explanation of the practice which experience has eſtabliſhed as the moſt ſucceſsful in this diſeaſe. Firſt Lines, § 1196.

Cauſes of Indigeſtion.—Certain original conſtitution of the body is obviouſly connected with a prediſpoſition to this complaint: this is ſometimes manifeſt only in a defective performance of the functions of the ſtomach itſelf; but in other caſes it is evidently a part of the general want of tone and vigour in the body, and occurs in perſons of lax fibre, and ſanguine or ſanguineo-phlegmatic temperament. In perſons of dark and ſallow complexion, the ſtomach itſelf appears to be often originally weak, in a degree diſproportionate to the general condition of the habit.

The *exciting cauſes* of indigeſtion, then, muſt be looked for among thoſe circumſtances which tend either to produce a loſs of tone in the muſcular fibres of the ſtomach, or which, in the debilitated ſtate of that organ, tend to oppreſs its powers and to impede its functions. The cauſes which contribute to impair the vigour of the ſtomach are of two kinds; namely, thoſe which operate directly upon that organ, and thoſe which affect it indirectly, or through the medium of the general ſyſtem.

The vigour of the ſtomach is impaired by the exceſſive uſe of ſtimulating condiments, and of ſpirituous liquors, as well as by the abuſe of certain articles of the ſedative or narcotic kind, ſuch as tobacco, tea, coffee, opium, bitters; and by the too frequent and copious uſe of acid and aceſcent articles of food, and of warm watery liquids. Frequent vomiting, whether ariſing ſpontaneouſly or excited by art, tends alſo greatly to debilitate the ſtomach; and over-diſtention of the organ by an exceſſive quantity of food or drink, or the uſe of food in itſelf difficult of digeſtion, or difficult from the idioſyncraſy of the individual, equally contribute to the ſame effect. The want of due maſtication, and of the proper commixture of the ſaliva with the food, by which its tendency to putrefactive decompoſition may be diminiſhed, likewiſe materially enfeebles the digeſtive powers of the ſtomach, and adds to the oppreſſion where it is already weakened. Whence the habit of frequent ſpitting, or rejection of the ſaliva, is juſtly enumerated among the cauſes of indigeſtion. Compreſſion of the ſtomach after a full meal, as by particular poſtures, &c., or violent exerciſe or ſucceſſion of the body, under the ſame circumſtances, have been found to have a material influence in preventing the proceſs of digeſtion, and oppreſſing the powers of the ſtomach. Hence various occupations and trades, in which compreſſion and ſucceſſion of the diſtended ſtomach are daily produced, occaſion habitual *dyſpepſia* in thoſe who are prediſpoſed to the diſeaſe.

Many of theſe occupations, however, debilitate the ſtomach likewiſe through the medium of the general ſyſtem, or by deranging other organs and functions with which the ſtomach particularly ſympathiſes. The ſedentary and inactive life, connected with many of them, debilitates the body in all its functions, and the ſtomach moſt particularly; intenſe ſtudy, or cloſe application of mind to any buſineſs, when long continued; grief, anxiety, vexation of mind, and diſorderly paſſions of any kind; venus immodica; expoſure to moiſt and cold air, when without exerciſe; and frequent intoxication, which belongs partly to this head, and partly to the former,—are all common remote cauſes of that imbecility of ſtomach which is connected with indigeſtion. Dr. Cullen remarks, that, though the diſeaſe, as proceeding from the laſt ſet of cauſes, may be conſidered as a ſymptomatic affection only; yet as the diſorder of the ſtomach is generally the firſt, always the chief, and often the only effect which theſe cauſes produce or diſcover; ſo the affection of the ſtomach may be conſidered as the diſeaſe chiefly to be attended to in practice; and the more properly ſo, as in many caſes the general debility is only to be cured by reſtoring the tone of the ſtomach, and by remedies firſt applied to this organ.

On the other hand, however, it is not to be omitted, that the ſtomach, from its extenſive ſympathy, by which it is often a partaker of morbid irritation ſeated in other organs, occaſionally diſplays ſymptoms of derangement ſo violent, and apparently ſo confined to itſelf, as to make the primary and proper ſource of the derangement be altogether overlooked. Many inſtances might be quoted of the ſucceſsful treatment of ſeemingly idiopathic dyſpepſia, by remedies which manifeſtly and chiefly operate upon other organs, and exert little or no immediate beneficial influence on the ſtomach. The viſcera, more immediately concerned in the function of digeſtion, eſpecially the liver, and the alimentary canal, are often the ſeat of the original irritation in ſuch caſes; the kidneys and the uterus occaſionally produce ſimilar effects.

Treatment of Indigeſtion.—In attempting to cure this ſtate of the ſtomach, we may conſider the following indications as the principal points to be purſued: *firſt*, to avoid, or remove, or, as far as may be, to regulate thoſe things which have been enumerated above as the ordinary exciting cauſes of the diſeaſe; *ſecondly*, to palliate or remove thoſe urgent ſymptoms, which eſpecially contribute to aggravate and continue the diſeaſe; and *thirdly*, to reſtore the tone and vigour of the ſtomach, and of the ſyſtem at large.

The propriety and neceſſity of the firſt indication is ſufficiently evident, as the continued application, or frequent repetition of thoſe cauſes, muſt neceſſarily tend to continue the diſeaſe, to defeat the efficacy of remedies, or to occaſion the recurrence of the diſorder in ſpite of the operation of theſe. Dr. Cullen juſtly remarks, that it is commonly owing to the neglect of this indication, that this diſeaſe is ſo frequently obſtinate in its duration. It would be ſuperfluous to enumerate the various modes of fulfilling this indication, which will be ſufficiently obvious from the conſideration of the ſeveral cauſes: but this circumſtance evinces the importance of minutely inveſtigating the origin of the diſorder, previous to the adminiſtration of remedies, and of aſcertaining whether the dyſpepſia be conſtitutional or acquired, whether idiopathic or ſymptomatic, whether owing to any organic derangement of the ſtomach, ſuch as tumour, ulcer, or ſcirrhoſity, or whether ariſing merely from errors in diet, or other extrinſic agents. It muſt be obſerved, however, that the accompliſhment of this firſt indication is often exceedingly difficult: for, in many caſes, the circumſtances of the patient will not admit of any material change; his avocations themſelves, upon which his ſubſiſtence depends, comprehend, perhaps, the principal cauſe of the miſchief. More frequently, the obſtacles ariſe from the difficulty of inducing men to break in upon eſtabliſhed habits, or to renounce the purſuit of pleaſure; and eſpecially, to perſuade them that thoſe practices, which they have often repeated, and ſeen others repeat, with ſeeming impunity, are in reality prejudicial.

Some allowance, indeed, is neceſſary to be made for the influence of habit, in all changes that relate to the animal economy, and eſpecially where theſe habits have been carried to the extreme. For if the ſtomach have been long accuſtomed to exceſſive ſtimuli, whether from condiments or ſpirituous liquors, the total abſtraction of theſe from the diet might occaſion a direct debility, under which the powers of life might ſink. Under ſuch circumſtances, therefore, ſome degree of the accuſtomed ſtimulus muſt be for ſome time indulged in, or ſome leſs prejudicial one ſubſtituted. But the apprehenſions of danger, from great changes in the habits of life, which are generally entertained, are carried to an extent which experience does not juſtify. Almoſt all the general rules which can be laid down, in reſpect to the wholeſomeneſs of certain articles of diet, admit of exceptions from peculiarities of conſtitution in particular individuals. Some indications on this point, however, may be obtained by attending to the obvious prevailing ſtate of the ſtomach, as evinced by the acid or nidorous eructations, &c. The acid ſtate of the ſtomach implies the neceſſity of diminiſhing the proportion of vegetable food; while the nidorous condition may be benefited by augmenting that part of the diet, and leſſening the quantity of animal food. It is of much importance that the whole quantity of food ſhould be ſuch as not to overload the ſtomach, or occaſion conſiderable diſtention. There is a common precept, under which great errors are ſometimes committed, in the way of overloading the ſtomach, or at leaſt of exhauſting its digeſtive powers, namely, that of eating little and often, ſo that long faſting may be avoided on the one hand, and too much repletion on the other. With the view of fulfilling this precept, an almoſt inceſſant ſupply of aliment is ſometimes thrown into the ſtomach; ſo that the digeſtion of one portion is never completed, before another is combined with it in a crude ſtate, thus aggravating the crudities which the diſeaſe itſelf produces, or preventing their more effectual aſſimilation.

In fulfilling the *ſecond* indication, of removing urgent ſymptoms, one of the firſt objects purſued by ſome practitioners, is that of removing the crudities of the ſtomach produced by the diſeaſe, by means of emetics: Dr. Cullen himſelf appears to be the advocate of this practice. (Firſt Lines, par. 1204.) Nevertheleſs, as theſe crudities are commonly the effect of the diſeaſe, and not the cauſe, the expulſion of them from the ſtomach by vomiting can afford but a brief and temporary relief; and the ſame uneaſineſs will recur after the firſt or ſecond meal. And, moreover, experience has ſhewn us, that frequent vomiting, however excited, tends to weaken the ſtomach, to diminiſh its powers of digeſtion, and to render it leſs able to retain what is thrown into it, and therefore ultimately to aggravate the ſymptoms which it was intended to relieve. "They are unhappy," ſays the ſame phyſician in another place, "who truſt to this mode of relief, and have frequent recourſe to it; for I am certain, from much experience, that frequent vomiting hurts the tone of the ſtomach, and often makes the ſymptoms of digeſtion recur more frequently and ſooner than they otherwiſe would have done." (Cullen on Mater. Medica, vol. ii. p. 465. See alſo EMETICS.) We have ſtated under that article, the circumſtances which have led to the erroneous ſuppoſition, that the indigeſtion and its concomitant ſymptoms originate in the preſence of bile and other extraneous fluids in the ſtomach; and explained how the diſcharge of bilious and mucous matters from the ſtomach, under the operation of an emetic, may be the effect of the vomiting, although they might not previouſly have been lodged there. In ſhort, there are few inſtances of *dyſpepſia* in which the uſe of emetics can be deemed beneficial.

Of the other urgent ſymptoms, which require to be palliated, the principal are *acidity*, and its frequent concomitant, *heart-burn*,—pain in the ſtomach,—the ejection of a copious and clear fluid, or *water-braſh* (as it is termed in Scotland),—and *conſtipation* of the bowels. It will not be neceſſary for us to dilate upon the method of treating theſe ſymptoms here, ſince they will be found amply diſcuſſed under their proper heads; as they are often ſo peculiarly diſtreſſing to the patients, as to be conſidered themſelves the principal diſeaſes, and to be the principal ſubject of complaint. We may briefly obſerve, that the preſence of acid in the ſtomach in a morbid degree is known, not only by its riſing occaſionally into the mouth and throat by eructation, and by the heart-burn which accompanies it (ſee Cardialgia); but alſo by the occurrence of gnawing pains in the ſtomach, flatulency, irregular cravings for food, griping and looſeneſs of the bowels, &c. The acidity already preſent in the ſtomach may be corrected, by neutralizing it by means of a chemical combination with ſome alkali or abſorbent earth. The three alkalis, ſoda, potaſs, and ammonia, may be taken for this purpoſe reſpectively, either in the pure (or cauſtic) ſtate, or mild, *i. e.* in the form of carbonates: on the whole, they ſeem to be more efficacious in the pure ſtate. The ſoda-water, now manufactured in the ſhops, is an agreeable form of antacid; but the alkali may be taken with advantage in larger quantities than that beverage contains. Magneſia, chalk, and the teſtaceous powders prepared from crabs-claws and oyſter-ſhells, which are carbonates of lime, likewiſe combine with the gaſtric acid, and neutralize it: the magneſia (which is much more effectual in its pure ſtate, or calcined, than in the form of carbonate) is often uſeful, inaſmuch as it forms a neutral ſalt, which is in ſome degree laxative, with the acid of the ſtomach. It is not, however, ſufficient to neutralize the preſent acidity, the diſpoſition to generate it muſt be alſo obviated. This is to be effected partly by avoiding aceſcent aliments of the vegetable claſs, and uſing animal food, ſuch as is little capable of aceſcency. But as vegetable food cannot be entirely diſcarded, the exceſs of its aceſcency may be in ſome meaſure avoided, by chuſing ſuch vegetable matters as are the leaſt diſpoſed to the vinous fermentation, ſuch as leavened bread, and well fermented liquors; and inſtead of uſing the freſh native acids, employing vinegar. But the diſpoſition to acidity may be farther prevented by other means; namely, by thoſe which invigorate the muſcular fibres of the ſtomach, to be mentioned preſently. It appears that the acidity occurs in a morbid quantity, either from a change in the digeſtive fluids, becoming leſs fit to moderate the natural progreſs to fermentation, or from their not being ſupplied in ſufficient quantity; both of which probably ariſe from a weakened action of the ſtomach. For it is obſerved, in ſome inſtances, that ſedative or depreſſing paſſions immediately occaſion the appearance of acidity in the ſtomach, which did not appear before; and alſo that the uſe of ſtimulants, applied to the ſtomach, often corrects or obviates an acidity, that would otherwiſe have appeared.

Of that ſymptom of the dyſpeptic ſtate of the ſtomach, which is a common concomitant of indigeſtion, *pain*, or *ſtomach-colic*, *gaſtrodynia*, we have already treated at length. (See the laſt term.) Having there ſtated the various circumſtances under which it occurs, and eſpecially in the two oppoſite ſtates of repletion and inanition, as well as the method of cure, which ſucceed in theſe two conditions reſpectively, we deem it unneceſſary to repeat the obſervations here.

In fulfilling the ſecond indication, another ſymptom which requires particularly to be obviated is *coſtiveneſs*. There is ſo much connection between the ſeveral portions of the alimentary canal with reſpect to the periſtaltic motion, that if accelerated or retarded in any one part, the other parts of it are commonly affected in the ſame manner. Thus as the briſker action of the ſtomach muſt accelerate the action of the inteſtines, ſo the ſlower action of the inteſtines muſt in ſome meaſure retard that of the ſtomach. It is therefore of conſequence to the proper action of the ſtomach, that the periſtaltic motion of the inteſtines, determining their contents downwards, be regularly continued, and that all coſtiveneſs, or interruption of that determination, be avoided. But an indiſcriminate uſe of cathartic medicines is much to be deprecated. For it muſt be obſerved, that, as every conſiderable evacuation of the inteſtines weakens their action, and tends therefore to induce coſtiveneſs when the evacuation is over; ſo thoſe purgatives which produce a large evacuation are unfit for correcting the habit of coſtiveneſs. The milder cathartics, therefore, are the moſt ſuitable for this purpoſe, which do no more than ſolicit the inteſtines to a more ready diſcharge of their preſent contents, without either hurrying their action, or increaſing the excretions into their cavity; either of which might produce a purging. Dr. Cullen was of opinion, that medicines which particularly ſtimulate the large inteſtines, and act little on the higher parts of the inteſtinal canal, were peculiarly proper for this purpoſe, ſuch as the aloetic, and other reſinous purgatives. Theſe medicines certainly produce a very beneficial operation in numerous inſtances, probably by ſupplying the place, as it were, of the bile, which appears to be the natural tonic and laxative to the inteſtines, and which is often both deficient in quantity, and depraved in quality, in dyſpeptic habits. The augmentation and correction of this fluid is often an important object in the treatment of indigeſtion, and the changes in the appearance, odour, and conſiſtence of the ſtools, as well as the preſence or abſence of griping, teneſmus, heat and irritation in the ſeat, &c., are among the principal diagnoſtic ſymptoms in regard to the condition of the bile, which ſeems to be the chief cauſe of the variations of the alvine diſcharge. (See Abernethy's Obſervations on the Diſ. of the Health, &c.) For the purpoſes of augmenting and correcting the biliary ſecretion, the milder preparations of mercury, which require to be varied according to circumſtances, which have not yet been accurately deſcribed, appear to be the moſt effectual agents. It is probable that the long expected treatiſe of Dr. James Curry will contribute materially to elucidate this important ſubject; and we truſt that we ſhall be able to avail ourſelves of the aſſiſtance of that work, before we compoſe our article on the *chronic diſeaſes of the* Liver.

The peculiar modification of dyſpepſia, called by the Scotch *water-braſh*, the *Cardialgia ſputatoria* of Linnæus, (Gen. Morborum, Claſs iv. Ord. 1.) and the *Pyroſis* of Cullen, (for which we have no appropriate Engliſh name,) is a ſufficiently diſtinct diſeaſe to be diſcuſſed in a ſeparate article. See Pyrosis. See alſo Flatulence, Nausea, and Vomiting.

The *third* indication, which is properly the curative one, is to reſtore the tone and vigour of the ſtomach, the loſs of which is deemed the principal ſource of the diſeaſe. The means of accompliſhing this indication may be referred to two heads; one of which includes thoſe means which operate directly and chiefly on the ſtomach itſelf; and the other, thoſe which, operating upon the whole ſyſtem, communicate their tonic powers ſecondarily to the ſtomach.

The medicines which operate directly on the ſtomach, compriſe all thoſe articles which are denominated *tonics*, and many of thoſe called *ſtimulants*, and *aſtringents*.—The bitter vegetable ſubſtances, or *bitters*, as they are emphatically called, and eſpecially thoſe which combine ſome aromatic quality with their bitterneſs, are moſt frequently preſcribed for this purpoſe, and poſſeſs very conſiderable efficacy. Such are the roots of gentian, colomba, and rhubarb; the bark of cinchona, caſcarilla, &c.; the quaſſia wood; the flowers of chamomile; and many other vegetable productions. Experience, however, ſeems to have decided, that theſe bitters cannot be taken for a great length of time with impunity. Some have imagined that there is a certain quantity of a narcotic power reſident in them, which, though inſenſible in its effects for a conſiderable time, ultimately occaſions a deleterious influence on the conſtitution. This was particularly learned from the conſequences of a long-continued uſe of the celebrated Portland Powder, for the cure of the gout: a very large number of thoſe perſons who took that medicine, which conſiſted of bitters and aromatics, having died of apoplexy, or ſome other ſevere diſeaſe, after having been apparently much benefited by its uſe. When theſe medicines are taken, therefore, with a view to reſtore the tone and vigour of the ſtomach, it is adviſable not to employ them unremittingly for a great length of time; but to ſuſpend the uſe of them occaſionally for a conſiderable period, ſubſtituting ſome other corroborant medicines, if neceſſity require them. Among theſe the *mineral acids* are important adjuvants, eſpecially the ſulphuric (or vitriolic) and muriatic acids; which have not only a direct tonic power upon the ſtomach, increaſe the appetite, and aid digeſtion, but alſo tend to prevent the proceſs of fermentation in the food taken in. In this way, probably, their efficacy in preventing the formation of acidity in the ſtomach, and the heart-burn, &c. ariſing from ſuch acidity, is to be explained. It is certain, that, in many inſtances, where the alkalies and abſorbents have failed to obviate acidity and its conſequences, connected with indigeſtion, the free uſe of one or other of the mineral acids has effectually remedied the diſorder. *Aromatic* ſubſtances ſtimulate the ſtomach, and frequently therefore relieve aceſcency, flatulence, and cardialgia; *e. g.* cinnamon, ginger, capſicum, &c. but their ſtimulus is tranſitory, and if they are frequently repeated, and taken in large quantities, they may injure the tone of the ſtomach. *Chalybeate* medicines, or the various preparations of iron, are often employed as tonics, in the cure of indigeſtion; and they may be adminiſtered in conſiderable quantities with ſafety. They have not, however, been found ſo efficacious in the cure of indigeſtion, as the remedies above-mentioned; and they are principally taken in the form of *chalybeate waters*. But it is certain that theſe waters contain in general a very ſmall proportion of ſteel; and that other preparations of the ſteel are adminiſtered in much larger quantities without producing thoſe ſalutary effects, which are often aſcribed to the mineral waters; it is, therefore, probable that the benefits, which are obſerved to accrue during the uſe of theſe waters, are generally the reſult of other circumſtances connected with the drinking of them.

For, in fact, the moſt eſſential means of fulfilling the third indication are thoſe which ſtrengthen the ſyſtem at large, and thus indirectly reſtore the vigour of the ſtomach; and among theſe, *exerciſe* claims our firſt notice. We have ſhewn, in its proper place, the mode in which exerciſe operates, in promoting the full and perfect circulation of the fluids through all the organs of the body, and therefore in perfecting the performance of all the functions. (See EXERCISE.) But we may remark, with Dr. Cullen, that it in a particular manner ſtrengthens the ſtomach by promoting perſpiration, and exciting the action of the veſſels on the ſurface of the body, the ſkin having a peculiar ſympathy with the ſtomach. In this inſtance, however, as in every other operation of the animal economy, moderation muſt be the leading rule; for, although the ſteady and free circulation through the cutaneous veſſels conduces to a ſympathetic ſupport of the action of the ſtomach; yet exceſſive perſpiration, ariſing from over-action of theſe veſſels, is followed by a languor and partial torpor, which is alſo communicated to the ſtomach; inſomuch that ſickneſs, and total loſs of appetite are often the immediate reſults of violent exerciſe, attended with profuſe perſpiration. Regular exerciſe on horſeback has been generally found the moſt effectual means of ſtrengthening the ſtomach, and of curing indigeſtion.

Cold bathing is another important mode of reſtoring both general and local vigour; but unleſs it be reſorted to with ſome diſcrimination, like other active agents upon the animal frame, it may be productive of much detriment. In order to obtain benefit from the external application of cold, a certain degree of vigour in the circulation, eſpecially in the veſſels of the ſkin, ſhould be preſent. In the dyſpeptic ſtate, the temperature of the ſkin is liable to be defective, and the cutaneous circulation to be feeble; and under ſuch circumſtances, ſo far from giving ſtrength to the conſtitution, or to the ſtomach, the powers of life are depreſſed by the uſe of the cold bath, and the digeſtive organs ſympathize in the torpor, produced in the ſkin. The tepid or warm bath is more beneficial when this condition of the ſyſtem exiſts, and the baths of Buxton and Matlock may be reſorted to with advantage; the ſame principle, however, muſt be kept in view in the uſe of theſe; which muſt not be entered with a chilly and ſhuddering ſurface; nor the immerſion be repeated, if a glow does not ſucceed. See COLD, *as a remedy*.

In conſequence of the great ſympathy between the ſtomach and the ſkin, the proper regulation of the *clothing* is a matter of conſiderable importance to thoſe who are liable to indigeſtion; and as the temperature, though variable, is moſt frequently below the ſtandard of health, ſo in general warmth is a neceſſary quality to be maintained. This is moſt particularly required in the extremities, in which the circulation is neceſſarily moſt languid, in conſequence of the greater diſtance from the heart; warmth and dryneſs of the feet, therefore, are peculiarly ſerviceable in the cure and prevention of dyſpepſia; and for thoſe whoſe temperature is eaſily diminiſhed by external cold, the general ſtimulus and ſlow-conducting power of woollen garments, worn next the ſkin during the winter months, may be conſidered as affording much ſecurity from the attacks of indigeſtion. But as profuſe perſpiration is generally accompanied by ſome degree of ſympathetic debility in the ſtomach, theſe garments ſhould not be uſed, during the hot ſeaſons, by thoſe whoſe ſkin is readily brought into a perſpirable ſtate.

A relaxation of the mind from the anxieties of buſineſs and the fatigues of ſtudy, and the purſuit of objects of amuſement, contribute materially to the well-being of the animal economy, and eſpecially to the proper performance of the digeſtive functions. This object is more particularly to be conſidered, when there is a tendency to hypochondriaſis. And as we have already obſerved, it is probably from the amuſements and regular exerciſe, which are generally enjoyed at watering places, as they are called, that more benefits accrue to the dyſpeptic invalids, than from the virtues of the mineral ſprings, theſe places of reſort may be recommended.

Before we conclude this topic, it may be proper to ſtate, that ſeveral contemporary phyſicians and ſurgeons have obſerved, that a diſordered condition of the digeſtive organs, however induced, becomes the cauſe of many ſecondary diſeaſes, both general and local; ſuch as ſuperficial ulcerations, pains, tumours, &c.; which ſpontaneouſly ceaſe, when the diſorder of the digeſtive organs is removed. We may remark, however, that it is not every diſorder of digeſtion which is followed by theſe conſequences; and that it is rather in the morbid condition of the *biliary* ſecretion, than of the ſtomach itſelf, that the diſorder alluded to conſiſts. Its ſymptoms are thus deſcribed by Mr. Abernethy. "This ſlighter diſorder of the chylopoietic organs is, in general, manifeſted by a diminution of the appetite and digeſtion, flatulence, and an unnatural colour and fœtor of the excretions, which are generally deficient in quantity. The tongue is dry, whitiſh, or furred, particularly at the back part: this ſymptom is moſt apparent in the morning. The fur is greateſt at the back part, and extends along the middle of the tongue to the tip, the edges remaining clean. As the diſeaſe advances, a tenderneſs is felt when the epigaſtric region is compreſſed, and the patient breathes more by the ribs, and leſs by the diaphragm, than in the healthy ſtate. The urine is frequently turbid." (Abernethy on the Conſtitut. Origin of Local Diſ.) In whichſoever of the organs concerned in digeſtion this morbid condition may be principally ſeated, the others participate, and various effects follow, in the manner thus deſcribed by Mr. Abernethy. "It is generally admitted, that diſorders of the chylopoietic viſcera will affect the ſource of ſenſation, and conſequently the whole body; but the variety of diſeaſes, which may reſult from this cauſe, has not been duly weighed and reflected on. It may produce, in the nervous ſyſtem, a diminution of the functions of the brain, or a ſtate of excitation, cauſing delirium; partial nervous inactivity and inſenſibility, or the oppoſite ſtate of irritation and pain. It may produce, in the muſcular ſyſtem, weakneſs, tremors, and palſy; or the contrary affections of ſpaſm and convulſions. It may excite fever, by diſturbing the actions of the ſanguiferous ſyſtem; and cauſe various local diſeaſes, by the nervous irritation which it produces, and by the weakneſs which is conſequent on nervous diſorder or imperfect chylification. Or if local diſeaſes occur in a conſtitution deranged in the manner which I have deſcribed, they will become peculiar in their nature and progreſs, and difficult of cure. Affections of all thoſe parts which have a continuity of ſurface with the ſtomach, as the throat, mouth, lips, ſkin, eyes, noſe, and ears, may be originally cauſed or aggravated by this complaint." Whenever, therefore, local diſeaſes are connected with this ſlight derangement of the digeſtive organs, the firſt care will be to correct this derangement, as the moſt important ſtep towards the cure of the former. For while the ſecretion of bile is either defective, or depraved in quality, (of which the appearances of the alvine diſcharge afford the beſt index,) the local or general ſymptoms of diſorder, connected with this condition of the hepatic function, will not yield to remedies that would otherwiſe ſeem to be appropriate, and readily effect a cure.

INDIGETES, a name which the ancients gave to ſome of their gods.

There are various opinions about the origin and ſignification of this word; ſome pretending it was given to all the gods in general; and others only to the ſemi-gods, or great men deified. Others ſay it was given to ſuch gods as were originally of the country, or rather ſuch as were the gods of the country that bore this name; and others again hold, it was aſcribed to ſuch gods as were patrons and protectors of particular cities.

Laſtly, others hold indigetes to be derived from *inde genitus*, or *in loco degens*, or from *inde* and *ago*, for *dego, I live, I inhabit;* which laſt opinion ſeems the moſt probable.

In effect it appears, 1. That theſe indigetes were alſo called *local gods*, *dii locales*, or *topical gods*, which is the ſame thing. 2. The indigetes were ordinarily men deified, who indeed were, in effect, local gods, being eſteemed the protectors of thoſe places where they were deified; ſo that the ſecond and third opinion are very conſiſtent. 3. Virgil joins *patrii* with indigetes, as being the ſame thing, Georg. i. ver. 498. *Dii patrii*, indigetes. 4. The gods to whom the Romans gave the name indigetes were, Faunus, Veſta, Æneas, Romulus, all the gods of Italy; and at Athens, Minerva, ſays Servius; and at Carthage, Dido. It is true, we meet with Jupiter *indiges*; but that Jupiter *indiges* is Æneas, not the great Jupiter; as we may ſee in Livy, lib. i. cap. iii. in which laſt ſenſe Servius aſſures us, *indiges* comes from the Latin *in diis ago, I am among the gods.*

Among theſe indigetes gods, there is none more celebrated, nor more extenſively worſhipped, than Hercules.

INDIGHIRKA, in *Geography*, a river of Ruſſia, which riſes in nearly 64 N. lat., in the Stanovoi-Krebet, and being reinforced by the Amekon and a multitude of ſmaller rivers, falls, in four great arms, into the Frozen ocean, N. lat. 73° E. long 144° 14′.

INDIGNATORIUS, in *Anatomy*, a muſcle thus called, as being ſuppoſed to draw the eye from its inner corner outwards, which gives an appearance of ſcorn and anger.

But this is properly a compound motion of two muſcles; for which, ſee EYE.

This muſcle is called by others the rectus exterior, and abducens; and by Albinus, the abductor. It is one of his quatuor recti oculi.

INDIGO, or ANIL, *Botany*. See INDIGOFERA.

From this plant is extracted a dyer's drug, of a deep blue colour, brought hither from the Weſt Indies and America. It is alſo made in the Eaſt Indies, particularly in the dominions of the Great Mogul, the kingdom of Golconda, &c.

The ancients were acquainted with the dye, which we call indigo, under the name of "Indicum." Pliny knew that it was a preparation of a vegetable ſubſtance, though he was not juſtly informed concerning the plant itſelf, and the proceſs by which it was fitted for uſe. From its colour, and the country from which it was imported, it is denominated by ſome authors "Atramentum Indicum" and "Indicum nigrum." Even at the cloſe of the 16th century it was not known in England what plant produced indigo. Gerarde, in 1597, is wholly ſilent about it, and ſo is Johnſon in 1632. Parkinſon, however, in 1640, treats largely of it. He calls it "Indico or Indian woade," and gives a figure of the leaf from De Laet. He then deſcribes it, firſt from Francis Ximenes in De Laet's deſcription of America; and ſecondly, from Mr. William Finch, a London merchant, in Purchas's Pilgrims. Even in 1688 Mr. Ray ſays it was not agreed among botaniſts what plant it is from which indigo is made; but that the moſt probable opinion was, that it is a leguminoſe ſhrub, allied to Colutea. He deſcribes it from Hernandez and Margraaf; and ſubjoins that of the "Ameri" from the Hortus Malabaricus. *Nil* or *Anil* is the American name. In Arabic it is *Nile*. The Portugueſe have adopted their *Anil* or *Anileira* from the American. The other European nations generally call it *Indigo*. In Chineſe it is *Tien laam*, which ſignifies ſky-blue. Mr. Miller cultivated the dyer's indigo ſo long ago as the year 1731; and calls it Guatimala indigo, ſaying that with us it is an annual plant. Specimens of the *Indigofera tinctoria*, or dyer's indigo, from different parts of India, Madagaſcar, Java, Ceylon, &c. vary very much, if they are all really the ſame ſpecies. Linnæus ſays that it is almoſt an exotic in Ceylon, but frequent in Paliacotta and Coromandel. According to Loureiro it is ſpontaneous in China and Cochinchina, and is cultivated all over thoſe vaſt empires. Dr. Patrick Browne, beſides the wild indigo already mentioned, has two others, which he calls the indigo, and the Guatimala indigo; the former yielding more of the dye than either of the others, is generally preferred, though ſubject to many more miſchances.

It has been generally believed, that the indigo plant flouriſhes only in the climate of the torrid zone, and in thoſe parts of the temperate zone which are near the tropics. But experiments lately made in Italy by Bruley, by order of government, have proved that, in a ſuitable ſoil and expoſure, and with good ſeed, it may be cultivated in a ſoutherly climate. Accordingly, he has obtained the indigo plant in the gardens of the Chateau de la Venerie, near Turin; and by ſubmitting it to the proceſs employed at St. Domingo, he has extracted an indigo which might bear compariſon with the fineſt indigo of the colonies. His plantations were made towards the end of February. M. Icard de Bataligni, another coloniſt, cultivated the plant in 1805, in the department of Vaucluſe, in France; and his reſults confirm the hopes formed with reſpect to the culture of indigo in Europe.

Labat has given a particular account of the culture of the plant, and the preparation of the indigo. The ground being thoroughly cleared from weeds (one of the principal points in the culture), and, we may add, drained, a number of ſlaves, ranged in a line, march acroſs, making little trenches of the width of their hoes, and two or three inches deep, about a foot diſtance from one another every way: then, returning, they drop ſome ſeeds in each trench, and afterwards cover them with the earth taken out. The ſoil, it is obſerved by others, ſhould be free and rich, and the climate warm: and the ſeaſon of ſowing ſhould be rainy; as the earth muſt either already have imbibed water, or rain muſt ſpeedily follow the ſowing; otherwiſe the ſeed becomes heated, corrupts, and is loſt, after all the labour it has occaſioned. During the proceſs of vegetation the ground muſt be carefully weeded, in order to prevent any mixture of herbs, which would injure the indigo in its manufacture. In moiſt weather, the plant comes up in three or four days; and in about two or three months after, it is fit for cutting: if ſuffered to ſtand till it runs into flower, the leaves become too dry and hard, and the indigo obtained from them proves leſs in quantity, and leſs beautiful: the due point of maturity is known, by the leaves beginning to grow leſs ſupple, or more brittle. In rainy ſeaſons, the cutting may be repeated every ſix weeks: cutting in dry weather kills the plant, which, if that is avoided, continues to afford freſh crops for two years.

A large quantity of the herb is put into a vat or ciſtern of ſtrong maſon work, with ſo much water as is ſufficient to cover it; and ſome wood laid above to prevent its riſing up. The matter begins to ferment, ſooner or later, according to the warmth of the weather, and the maturity of the plant, ſometimes in ſix or eight hours, and ſometimes not in leſs than twenty. The liquor grows hot, throws up a plentiful froth, thickens by degrees, and acquires a blue colour, inclining to violet. In proportion as the caloric increaſes, azote is diſengaged, the herbaceous mucilage ſeparates, the vegetable is diſcompoſed, and the mixture abſorbs oxygen. The fermenting fluid paſſes from a green to a violet tinge, and this by degrees changes to a blue colour. The great art of the manufacturer is to check the fermentation at a proper degree. If the fermentation is too feeble or too brief, the plant remains impregnated with much eſſential ſalt, which diminiſhes the quantity of indigo. If it be too long, the tender extremities of the plant undergo a putrefaction which deſtroys the colour. Some years ago, the following criterion was publiſhed at St. Domingo, for aſcertaining invariably the correct fermentation of the indigo. It is only requiſite to write on white paper with the matter to be examined. If this ink be of very high colour, it is a proof that the fermentation is not yet at its true point. The experiment is repeated every quarter of an hour, till it is perceived that the liquid has loſt its colour. This was pronounced an infallible index to ſhew the true point of fermentation. Others, however, judge of the proper ſtage of fermentation by means of a ſilver cup, into which they throw the liquid, ſhaking it till grains are formed; by their quality, and that of the fluid, they judge of the fermentation. When the feculent particles begin to precipitate to the bottom of the cup, it is then judged, that the herbs have attained the true degree of maceration for obtaining indigo. It has been obſerved, however, that this procedure often led into error; and, therefore, five or ſix minutes after the liquid has been put into the cup, it was perceived to form round its ſides a cordon of feculæ, or ſediment, at firſt of a green colour, and then blue. When the maceration is not at the requiſite point, this cordon, or girdle, detaches itſelf with difficulty from the ſides of the cup, but finally precipitates, and concentres at the bottom, always towards the centre, and the water above it becomes limpid, though of a yellowiſh tinge. When theſe ſigns are perceived, they indicate infallibly the ſucceſs of the firſt operation. At this time, without touching the herb, the liquor impregnated with its tincture is let out, by cocks in the bottom, into another vat placed for that purpoſe, ſo as to be commanded by the firſt. The firſt vat is called the “ſteeper;” the ſecond and third are called the “beaters.”

In the ſecond vat, the liquor is ſtrongly and inceſſantly beat and agitated, with a kind of buckets fixed to poles, till the colouring matter is united into a body. A good deal of nicety is requiſite in hitting this point; if the beating is ceaſed too ſoon, a part of the tinging matter remains diſſolved in the liquor; if continued a little too long, a part of that which had ſeparated is diſſolved afreſh. The exact time for diſcontinuing the proceſs is determined by taking up ſome of the liquor occaſionally in a little cup, and obſerving whether the blue fecula is diſpoſed to ſeparate and ſubſide.

The facility with which the grain precipitates to the bottom of the beater, is an unequivocal ſign that the beating has arrived at the correct point.

The whole being now ſuffered to reſt till the blue matter has ſettled, the clear water is let off, by cocks in the ſides at different heights; and the blue part diſcharged by a cock in the bottom, into another vat. Here it is ſuffered to ſettle for ſome time longer, then farther drained in cloth-bags, or ſacks, and expoſed in ſhallow wooden boxes to the air, without expoſing it to the ſun, and carefully keeping it from the rain, till thoroughly dry.

Before it is perfectly dry, it is cut in ſmall pieces of an inch ſquare, which detach themſelves readily from the box, when the indigo is entirely dry. Yet, however well drained and dried the indigo may be, it always experiences, in the firſt months of its fabrication, a diminution ſufficiently evident to warrant a haſtening of the ſale. It is cuſtomary to pack the indigo in barrels, and thus to circulate it in commerce. Indigo is packed in ſacks of coarſe linen, and the ſack is covered with an ox's hide, ſo hermetically ſewed, that nothing can penetrate it. Theſe packets are called “ceroons.” They are much preferable to barrels, as they are more ſolid and more convenient for tranſportation. Two “ceroons” make the load of one animal.

The author above-mentioned, from whom the greateſt part of the foregoing account is extracted, obſerves farther, that the goodneſs of the indigo depends greatly upon the age of the plant; that before it has grown fully ripe, the quantity it yields is leſs, but the colour proportionably more beautiful; that probably the ſecret of thoſe whoſe indigo has been moſt eſteemed, is no other than cutting the herb at the time when it yields the fineſt colour; that the ſuperiority of ſome of the indigoes of the Eaſt Indies to thoſe of America, is perhaps owing to the former being prepared more curiouſly from only the leaves of the plant; and that by beating the herb in the ſteeping-vat, which has been practiſed by ſome with a view to increaſe the quantity, great part of the ſubſtance of the leaves and bark is blended with the water along with the colouring matter, and the indigo extremely debaſed.

It is ſaid that lime, or lime-water, is ſometimes employed in the beating-vat, to promote the ſeparation of the tinging particles from the water; and that the hardneſs or flintineſs of ſome ſorts of indigo is owing to an over proportion of this addition.

Pomet ſays, that the Indians of the village of Sarqueſſe, near Amadabat, uſe only the leaves of the indigo, and throw away the plant and branches; and from thence the moſt eſteemed indigo is brought.

Indigo is commonly divided, from the colour which it exhibits upon breaking, into three kinds, copper-coloured, purple, and blue. It is ſaid that the dyers uſe chiefly the firſt; and the calico-printers (for this drug gives a durable ſtain to linen as well as woollen) the laſt. On what particular circumſtances theſe different appearances depend, we know not; nor is it certainly known whether the real quality of the indigo has any connection with them. The deepeſt and livelieſt blue indigo, rubbed with the nail, appears like poliſhed copper; and ſolutions of all the ſorts, made in alkaline lixivia, aſſume alike a copper-coloured ſkin upon the ſurface.

Good indigo is moderately light, breaks of a ſhining ſurface, and burns almoſt wholly away upon a red-hot iron. It is quickly penetrated by water, and reduced into a kind of paſte; a conſiderable part is at the ſame time diffuſed through the liquor, and very ſlowly ſubſides. This is probably what Labat and Hellot mean by its diſſolving in water; for no part of the indigo really diſſolves; it cannot indeed be expected that it ſhould, from the proceſs by which it is obtained.

Indigo requires an equal quantity or more of fixed alkaline ſalt, to render it totally ſoluble in water. On digeſting the indigo, with a gentle heat, in the ſolution of the alkaline ſalt, a ſhining copper-coloured ſkin begins to appear, and gradually covers the whole ſurface: on agitating the matter, a large blue flower or froth ariſes, and the liquor underneath appears of a deep green. If woollen cloth, without any other preparation than moiſtening it with warm water, be dipped in this hot liquor, it comes out perfectly green, and changes almoſt inſtantly in the air to a fine blue. This is the common proceſs of dyeing blue.

Mr. Hellot deſcribes two indigo vats with urine; one of which is uſed hot, like the foregoing, and the other cold. The hot vat conſiſts of equal parts of indigo, alum, and tartar, digeſted in urine till the liquor becomes green. The cold one is prepared, by digeſting powdered indigo with vinegar for twenty-four hours, in the proportion of four pounds to about three quarts; then mixing the matter with about fifty gallons of urine, and ſtirring the whole together every night and morning, till the liquor turns green, and gathers a head like the common vat.

Indigo is fitted for printing on linen, by diluting it with water into the conſiſtence of a ſyrup; then adding ſome powdered pearl-aſhes, green vitriol, and lime newly ſlaked; with ſo much water, occaſionally, as will reduce them into the conſiſtence of thin paint; mixing the whole thoroughly together, and ſtirring the matter every now and then, till it gains a copper colour on the ſurface. The proportions uſed by the workmen are, two parts of indigo, one of pearl-aſhes, three of vitriol, and two of lime. The ſame compoſition, diluted with a ſufficient quantity of water (about ſix gallons to a pound of indigo), and boiled, gives a durable blue to tanned ſkins, whether dipped in hot or cold

Indigo digeſted in a moderate heat with different volatile alkaline ſpirits, gave only yellowiſh and browniſh red tinctures; with rectified ſpirit of wine, a reddiſh one; to lime-water, and to water acidulated with the vitriolic, nitrous, and marine acids, it gave no tincture at all.

The concentrated vitriolic acid unites with it into a ſmooth paſte, eſpecially if the indigo is previouſly well ground with powdered glaſs, ſand, or other like ſubſtances. The indigo is thus rendered ſoluble in boiling water along with the acid, ſo as to paſs through the pores of a filter; the ſolution, whilſt hot, appears of a deep bright green colour, like that made by fixed alkalies, but fades as it grows cold, and changes at laſt to a browniſh. Theſe experiments, which were many times repeated with the ſame event, ſeem to overturn Mr. Hellot's ingenious theory, which deduces the green colour of ſolutions of indigo from the common property of blue juices being turned green by alkalies; and the blue colour which the cloth acquires ſoon after it is taken out of the vat, from a ſeparation of the alkali. We here find, that a green ſolution of this concrete is obtainable by the ſtrongeſt of the acids, and that with volatile alkalies it diſcovers no tendency to greenneſs.

For the method of preparing SAXON *blue* and SAXON *green* from indigo, ſee thoſe articles.

Indigo is ſometimes uſed among the painters for paper-hangings, and ſuch groſs uſes, who grind and mix it with white to make a blue colour; for without that mixture it would paint blackiſh.

They alſo mix it with yellow to make a green colour. It is alſo uſed in dyeing, and by the laundreſſes, to give a blueiſh caſt to their linen.

In the Hortus Indus Malabaricus is an account of the plant whence indigo is drawn; the decoction of whoſe root is ſaid to be excellent againſt nephritic colics; its leaves, applied to the abdomen, good to promote urine; and the indigo itſelf is ſaid to be of good uſe in drying of tumours.

Some phyſicians have recommended indigo in the quantity of a drachm, while others look upon it as a poiſon; and in Saxony the internal uſe of it is prohibited.

INDIGO, *Baſtard.* See AMORPHA.

INDIGO *Mills.* For the purpoſe of effecting the ſolution and union of indigo with the liquid uſed along with it, for the purpoſes of dyeing, mills of various conſtructions are in uſe. In this proceſs trituration or friction is as much as poſſible avoided, and the pulverization is effected merely by bruiſing. For this two very ſufficient reaſons may be aſſigned; the firſt, in point of economy, and the ſecond, to avoid chemical inconveniency. On whatever ſubſtance the indigo was triturated or rubbed, a certain proportion of the ſtuff would be mixed or incorporated along with the pulverized indigo, and that proportion of indigo which was abſorbed by this ſtuff would be either totally loſt, or brought into union with another ſubſtance which might prove uſeleſs, and probably injurious in the ſubſequent proceſs of dyeing. If the former only was the caſe, the abſorbed indigo would be totally loſt; if the ſecond took place, the whole proceſs might be utterly ſpoiled by the combination. In the appropriate plate, *fig.* 1. repreſents the ground or horizontal plan of ſuch an indigo mill as is generally uſed in ſmall dye-works, and which is occaſionally turned by a man's or boy's hand. This is tedious and laborious, for the operation muſt be continued for a very long time before the indigo is ſufficiently mixed with the liquid to be fit for uſe, and only a ſmall quantity can be put into the veſſel at once. *Fig.* 2. is an elevated ſection of the ſame mill.

In this machine the pulverization or granulation of the indigo is effected by the preſſure of a number of ſmooth caſt-iron balls, like thoſe uſed for the ſhot of great guns, which, being rolled among the indigo, preſs it into a paſte by their weight, until it unites with the liquid by which it is to be held in ſolution.

In *fig.* 1, A repreſents the bottom and rim of the veſſel which contains the indigo; and which is of a cylindrical form. B is an upright ſpindle, which, in this figure, does not appear. Upon the ſpindle B is fixed a wheel C C, with a convenient number of arms projecting round the veſſel, like the radii of a circle; and below each of theſe arms are projecting pieces of iron, like the pins or teeth of a harrow, for moving the balls. When this wheel C is moved round its axis, the whole balls in the veſſel A are ſet in motion, and, by rolling over the indigo, gradually preſs it, until it unites with the water or liquid with which it is ſurrounded. If the bottom of the cylinder be flat, a very ſmall part of the ſurface of each ball can act upon the indigo; but by caſting circular hollow grooves, as repreſented in *fig.* 2, nearly the ſemi-diameter of the ball will preſs upon the ſtuff. The mill is moved by a handle D, *fig.* 2, which ſets in motion the ſmall bevel wheel E, and this wheel acting upon the horizontal wheel F, fixed upon the ſpindle B, ſets it alſo in motion, and conſequently the wheel C C is moved round its axis, and all the balls roll round upon the indigo. G is a croſs ſhaft upon the top of the ſpindle B, loaded at each end with a heavy ball. There is generally another ſhaft placed at right angles to this, when they aſſiſt in regulating and equalizing the motion in the ſame manner as any other fly wheel. When the indigo is found to be ſufficiently diſſolved, and united with the water, the liquid thus formed is drawn off into any other veſſel for uſe by means of a vent and ſpiggot placed in any convenient part of the bottom of the veſſel.

The great labour and time which it requires, and the ſmall quantity of ſtuff which can be prepared at once by a machine of this kind, renders it ill adapted for the uſe of large works where much indigo is conſumed, and where they have generally a horſe-power water-wheel, or ſteam-engine, for raiſing water, cutting madder, and other purpoſes neceſſary in extenſive works. *Fig.* 3. repreſents an elevated croſs ſection of one of theſe machines, driven by any moving power, and capable of preparing a very great quantity of indigo at all times, as it requires no attendance, excepting to empty the veſſel when the indigo is wanted, and add a freſh ſupply. H is a ſemi-circular veſſel of caſt-iron, placed upon a ſtrong wooden frame O, and of any convenient length. I is a cover made in two pieces, with a circular aperture to admit the upright ſhaft K working upon the centre, or pivot P. At Q, the upright P is jointed to a horizontal ſhaft of wood M, the other end of which is connected by the joint R, with a crank fixed on the end of a horizontal ſhaft N driven by the moving power. The circular motion of the ſhaft and crank N communicates an alternate, or reciprocating motion, by means of the horizontal connecting ſhaft M, to the upper end of the upright ſhaft K, which vibrating upon the centre joint P, ſets in motion the iron cylinders L, L, in the body of the veſſel, which preſs upon the indigo, and produce the ſame effect, but to a much greater extent, as the balls in the machine firſt deſcribed. The cylinders L, L, may be made of any diameter or length which is found convenient. The greater maſs of iron that they contain, the quicker and more effectual will be their operation upon the ſtuff, provided there is a ſufficient power to drive them. The frame under the joint P extends the whole length of the ſemi-circular veſſel H, which may be any length, according to the extent of the power and quantity of work required. As this machine requires no attention whatever, it is found very uſeful in large dye works, as, by means of it, they can conſtantly command a large ſupply of prepared indigo, which may be drawn off when wanted, for the longer it is under the preparing proceſs, the better in every reſpect, and freſh indigo may be added as the ſupply gets low.

INDIGOFERA, in *Botany*, yields the blue dye called Indigo or Indicum, ſo eminently uſeful in dyeing various manufactures of a blue colour. This ſubſtance obtained the name of indigo from its native country, India.—Linn. Gen. 383. Schreb. 506. Willd. Sp. Pl. v. 3. 1220. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 3. 67. Juſſ. 359. Lamarck Dict. v. 3. 244. Illuſtr. t. 626. Gærtn. t. 148. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf, ſpreading, almoſt flat, five-toothed. *Cor.* papilionaceous; ſtandard rounded, reflexed, emarginate, ſpreading; wings oblong, obtuſe, ſpreading at the lower margin, of the ſhape of the ſtandard; keel obtuſe, ſpreading, deflexed, marked on each ſide by an hollow awl-ſhaped point. *Stam.* Filaments in two bundles, diſpoſed into a cylinder, aſcending at their tips; anthers ſomewhat roundiſh. *Piſt.* Germen cylindrical; ſtyle ſhort, aſcending; ſtigma obtuſe. *Peric.* Pod roundiſh, long. *Seeds* numerous, kidney-ſhaped.

Eſſ. Ch. Calyx ſpreading. Keel of the corolla having an awl-ſhaped ſpur on each ſide! Pod linear.

Obſ. Till within the laſt century it was but imperfectly made out what plants produced the dye known to the Romans by the name of *Indicum*. Mr. Miller, however, cultivated the *Indigofera* ſo early as 1731; but he was acquainted with only five ſpecies of it; which ſame number Linnæus imperfectly deſcribed. Profeſſor Martyn enumerates thirty-five ſpecies, and Willdenow fifty-one; but ſince this genus is particularly known and eſteemed for its utility in the arts, and that moſt of its ſpecies yield the blue dye, as well as many other plants of the ſame natural family, we ſhall merely give a general outline of the genus, without entering into a long ſyſtematic arrangement of the ſpecies.

The genus *Indigofera* is compoſed of ſhrubs and herbs, whoſe leaves are, in certain caſes, ſimple, more generally ternate, but moſt frequently unequally pinnate. The leaflets in ſome ſpecies are jointed and awned at the baſe. Stipulas diſtinct from the leaf-ſtalk. Peduncles axillary, generally many-flowered, in ſpikes or bunches. Many ſpecies are natives of the Cape of Good Hope; for inſtance, I. *filifolia*, *ſericea*, *depreſſa*, *ovata*, *pſoraloides*, *candicans*, *amæna*, *incana*, *procumbens*, *ſarmentoſa*, *denudata*, *erecta*, *coriacea*, *filiformis*, *digitata*, *fruteſcens*, *ſtricta*, *anguſtifolia*, and *capillaris*.—The reſt are either from the Eaſt or Weſt Indies, Arabia Felix, New Holland, and the coaſt of Guinea.

It is ſaid that Pliny was aware that *Indicum* was a preparation from a vegetable ſubſtance, though he was ill-informed both concerning the plant itſelf, and the proceſs by which it is made fit for uſe. The following is a curious anecdote to ſhew that at the cloſe of the 16th century it was unknown in England what plant produced Indigo, for in a book entitled "Remembrances for Maſter S. by Richard Hakluyt," written in 1582, Maſter S. is inſtructed "to know if Anile that coloureth blew, be a natural commodity of Turkey, and if it be compounded of an herbe—to ſend the ſeed or root with the order of ſowing, &c.—that it may become a natural commodity in the Realm, as woad is (*Iſatis tinctoria*), that the high price of foreign woad may be brought down."

I. *tinctoria*, Dyer's Indigo, is a native of the Eaſt and Weſt Indies, Madagaſcar, Ceylon, Java, &c. Its ſtem is ſuffruticoſe. Leaves pinnate, ovate. Bunches of flowers ſhort.—Loureiro ſays it is cultivated all over the vaſt empires of China and Cochin-china. It is figured under the name of Ameri in the *Hortus Malabaricus*, v. 1. 101. t. 54.

INDIGOFERA. See SOPHORA.

INDIKKOOD, in *Geography*, a town of Grand Bucharia; 60 miles W. of Balk. N. lat. 36° 38′. E. long. 64° 10′.

INDION, a town of Perſia, in the province of Choraſan, near the Masjan; 210 miles N.N.E. of Herat.

INDIRECT MODES *of Syllogiſms*, in *Logic*, are the five laſt modes, or moods, of the firſt figure, expreſſed by the barbarous words *baralipton, celantes, dabitis, feſpame, freſiſom*.

It is the converſion of the concluſion which renders the moods indirect: for inſtance, a ſyllogiſm in darii, and another in dabitis, would be perfectly alike, were it not for that converſion; the propoſitions having the ſame quantity, and the ſame quality, and the middle term being the ſubject in the major, and the attribute in the minor, in both. It remains, then, that, to make a diſtinction, that which is the ſubject of the concluſion in darii, be the attribute in the concluſion of dabitis; and that which is the attribute in the firſt, the ſubject in the laſt. See SYLLOGISM.

DA- Every thing that promotes ſalvation is advantageous:
RI- There are afflictions which promote ſalvation:
I. Therefore there are afflictions which are advantageous.
DA- Every thing that promotes ſalvation is advantageous:
BI- There are afflictions which promote ſalvation:
TIS. Therefore ſome things promoting ſalvation are afflictions.

INDIRECT *Confirmation*. See CONFIRMATION.

INDISCERNIBLES, in the *Philoſophy of Leibnitz*. See LEIBNITZIAN *Philoſophy*.

INDIVIDUAL, INDIVIDUUM, in *Logic*, a particular being of any ſpecies; or that which cannot be divided into two or more beings, equal or alike.

The uſual diviſion in logic is made into genera or genuſes, thoſe genera into ſpecies, and thoſe ſpecies into individuals. See GENUS, SPECIES, and DIVISION.

The ſchoolmen make a four-fold diſtinction of individuals; *viz*.

INDIVIDUUM *Vagum*, that which, though it ſignifies but one thing, yet may be any of that kind; as when we ſay a man, a certain perſon, or one ſaid ſo and ſo; though but one perſon is meant, yet that perſon, for aught that appears to the contrary, may be any body.

INDIVIDUUM *Determinatum* is, when the thing is named and determined; as Alexander, the river Nile, &c. this is alſo called *individuum ſignatum*.

INDIVIDUUM *Demonſtrativum* is, when ſome demonſtrative pronoun is uſed in the expreſſion; as, *this man, that woman*.

INDIVIDUUM *ex Hypotheſi*, or by ſuppoſition, when an univerſal name or term is reſtrained, by the ſuppoſition, to a particular thing: as when we ſay, the ſon of ſuch a one, and it be known that he had but one ſon.

INDIVISIBLES, in *Geometry*, thoſe indefinitely ſmall elements, or principles, into which any body or figure may be ultimately reſolved.

A line is ſaid to conſiſt of points, a ſurface of parallel lines, and a ſolid of parallel and ſimilar ſurfaces; and becauſe each of theſe elements is ſuppoſed indiviſible, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the ſame as the number of the elements.

Whence it appears, that a parallelogram, priſm, or cylinder, is reſolvable into elements, as indiviſible, all equal to each other, parallel, and like to the baſe; and a triangle into lines parallel to the baſe, but decreaſing in arithmetical proportion; ſo alſo are the circles which conſtitute the parabolic conoid, and thoſe which conſtitute the plane of a circle, or the ſurface of an iſoſceles cone.

A cylinder may be reſolved into cylindrical curve ſurfaces, having all the ſame height, and continually decreaſing inwards, as the circles of the baſe do, on which they inſiſt. This way of conſidering magnitudes, is called the method of indiviſibles, which is only the ancient method of exhauſtions, a little diſguiſed and contracted.

It is found of good uſe in ſhortening mathematical demonſtrations; of which we may give an inſtance in that famous propoſition of Archimedes, that a ſphere is two-thirds of a cylinder circumſcribing it.

Suppoſe a cylinder, an hemiſphere, and an inverted cone (*Plate* VIII. *Geometry, fig.* 102.) to have the ſame baſe and altitude, and to be cut by infinite planes all parallel to the baſe, of which $d g$ is one; it is plain, the ſquare of $d h$ will every where be equal to the ſquare of $k c$ (the radius of the ſphere) the ſquare $h c = e h$ ſquare; and, conſequently, ſince the circles are to one another as the ſquares of the radii, all the circles of the hemiſphere will be equal to all thoſe of the cylinder, deducting thence all thoſe of the cone; wherefore the cylinder, deducting the cone, is equal to the hemiſphere; but it is known, that the cone is one-third of the cylinder, and conſequently the ſphere muſt be two-thirds of it.

Cavalleri was the firſt perſon who introduced this method of indiviſibles into one of his works, entitled "Geometria Indiviſibilium," printed in 1635; which he alſo made uſe of in another tract publiſhed in 1647.

INDIVISO.—*Pro* INDIVISO. See PRO.

INDIVISUM FOLIUM. See LEAF.

INDO-SCYTHIA, in *Ancient Geography*, a diſtrict of India, that lay on the weſtern ſide of the river Indus, extending as far as the river Coas, or Cow river, and at preſent inhabited in part by thoſe who are probably deſcendants of the Scythian Nomades, and called *Nomurdy*.

INDOCTORUM PARLIAMENTUM. See PARLIAMENTUM.

INDORE, in *Geography*, a town of Hindooſtan, in the Malwa country, and reſidence of a Mahratta chief; 290 miles S.S.W. of Agra. N. lat. 22° 56′. E. long. 76° 11′.

INDORSEMENT, any thing written on the back of a deed or inſtrument. See ENDORSING.

A condition written on the back of an obligation is commonly called an indorſement: from *in*, and *dorſum*, *back*.

INDORSEMENT *of a Bill of Exchange*. See ENDORSEMENT.

INDOS, in *Geography*, a town of Hindooſtan, in Bengal; 16 miles E.N.E. of Biſſunpour. N. lat. 23° 10′. E. long. 87° 53′.

INDOUR, a town of Hindooſtan, in Tellingana; 15 miles N.W. of Indelavoy.

INDRA, in *Mythology*, is deemed, among the Pagan Eaſt Indians, the firſt of the demi-gods; and ſeems generally to rank in importance next to the three chief deities that form the Hindoo Trimurti. (See TRIMURTI.) The hiſtory of this firſt of their *dii minores* might be extended through ſeveral volumes; and, indeed, including the fables connected

connected with the motley hiſtory of this perſonage, many volumes thereon are extant among the Hindoos. He is ſaid, in their theogony, to be the offspring of Kaſyapa and Aditi (ſee KASYAPA), and has the whole firmament under his regency. In many particulars he correſponds with the Joves or Jupiters, for there were a great many among the Greeks and Romans; more eſpecially, perhaps, with Jupiter Pluvius, for Indra is the god of ſhowers. The Hindoos fancy the viſible heavens to be under the guidance of eight genii, collectively called Marûts, or the Winds. (See MARUT.) Of theſe, Indra is the principal, and he rules the eaſtern quarter. He may be deemed a perſonification of the firmament, ruling all atmoſpheric or meteoric phenomena. As god of thunder he is named Vajra Pani, or Lightning Sender; his diſk-ſhaped weapon, *vajra*, repreſents lightning. He reſides in the celeſtial city Umravati; his palace, Vaijayanta, is ſituated in the garden Nandana, which contains alſo the all-yielding trees Pariyataka, Kalpadruma, and three others ſimilarly bountiful. He poſſeſſes alſo the all-prolific cow Kamdenu, otherwiſe called Surabhi; and hence one of Indra's names means the *lord of wealth*. He has a conſort named Indrani: he rides the elephant Iravat, with three proboſci, which are ſaid to repreſent water-ſpouts, as the bow with which he is armed is the iris. Seated on mount Meru, or the north pole, attended by male and female dancers (Sinàra and Upsàra), he regales the gods with nectar and heavenly muſic. He is painted with four arms, and ſpangled with eyes; hence one of his names is the *thouſand-eyed* god. Another of his names is Purendera, or the *deſtroyer of towns*; he having, in revenge for ſuppoſed neglects, overwhelmed ſeveral cities; particularly Ujaini, or Oojein, the capital of Malwa.

INDRA *Malwa*, the hereditary poſſeſſion of the family of Sindia. The city has now lain ſubmerged about 1900 years. (See OOJEIN.) Indra is alſo named Shatkratû, meaning he to whom is made a *hundred ſacrifices*, for this "king of the immortals," another of his names, is very extenſively propitiated in the numerous ceremonies of luſtration and ſacrifice that Brahmans, devoted to the ſervice of the altar, are daily called upon to obſerve. Jealous, however, of the offerings made to other deities, he is repreſented as frequently interrupting, both by perſonal interpoſition and evil counſel, the ſacrifice prepared or intended for other deities: in this character of an evil counſellor he is uſually called Sakra, and although called and repreſented as *thouſand-eyed*, he is ſometimes painted with but one eye; the cauſe of which, with many other fables connected with the character and hiſtory of this important deity, is related in Moor's Hindoo Pantheon, whence moſt of the particulars of this article are taken.

Like moſt of the other Hindoo deities, Indra is repreſented as immoral and depraved, even to a proverbial degree; but we muſt refer to the work juſt mentioned for inſtances of his profligacy, exceſſively extravagant if received literally, but which, doubtleſs, are allegorical concealments of ſome aſtronomical or phyſical facts; for major Moor proves Indra to be a ſtar or a conſtellation of the northern hemiſphere, and that the wars which he ſuſtains againſt giants, in which he is alternately conqueror and conquered, refer to ſome cycle or periodical revolution of the heavenly bodies. Metallic images of Indra are rarely ſeen: he is ſculptured in Elephanta and other excavations in India, mounted on Iravat, and is often met with in paintings. Several engravings of him are given in the Hindoo Pantheon. Under the words ſeverally referred to above, and the foreign names of perſons and places that occur, farther particulars of the ſubjects of this article will be found; for Indra is ſo important a deity, that his hiſtory, like his worſhip, mixes itſelf with that of moſt of his divine aſſociates in the monſtrous ſyſtem of Hindoo idolatry.

INDRANI, is the name of the Sakti or conſort (ſee SAKTI) of Indra, the regent of the firmament among the Hindoos. (See INDRA.) Her name is ſometimes pronounced Aindrani. She is otherwiſe called Pulomaya, or Powlamya, and Saki, and is repreſented in the Hindoo Puranas, or mythological and theogonical romances, as a faithful and virtuous character, which is not always the caſe with their female divinities: ſhe is alſo very handſome, and has reſiſted many temptations. She is called one of the ſeven divine mothers of the celeſtials. (See MATRI.) In the ſixth volume of the Aſiatic Reſearches, is a very curious and intereſting account by ſir Charles Malet, of the magnificent excavations at Ellora, accompanied by plates; one of them repreſenting Indrani, of lovely form, ſeated on a lion, with a child in her lap, and a ſkull and croſs bones in her girdle: major Moor, however (Hindoo Pantheon, p. 271.), doubts if this elegant figure be really of Indrani, of whom he ſays he never ſaw any ſculptured repreſentation. See ELORA; to our account of which may be added, that Mr. Daniel has engraved and publiſhed, from materials in the collection of ſir Charles Malet, a ſeries of views, both minute and perſpective, of the interior and exterior of theſe wonderful excavations, that is altogether unrivalled by any work in Europe, as well for the accuracy of oriental ſcenery and coſtume, as for its general elegance and ſplendour.

INDRAPOUR, in *Geography*, a town on the W. coaſt of the iſland of Sumatra, and capital of a country, which has ſeveral other towns, where the Dutch have a factory for the purchaſe of pepper, 100 miles N. W. of Bencoolen. S. lat 2°. E. long. 100° 40′. This was once the ſeat of a monarchy of ſome conſideration and extent. Its antiquity appears from an hiſtorical account given by the ſultan of Bantam to Corneille le Brun, in which it is mentioned, that the ſon of the Arabian prince, who firſt converted the Javans to Mahometaniſm, about the year 1400, having got himſelf declared ſovereign of Bantam, married the daughter of the raja of Indrapour, and had, as her portion, the territory of the Sillabares, a people of Banca-houlou. This was probably the firſt diſmemberment which the Javan monarchs long availed themſelves of; and ſince, the kingdom of Indrapour has dwindled into obſcurity. From its ruins has ſprung that of Anacſoongey; extending on the ſea-coaſt from Mandoota river to that of Oori; the preſent capital of which, if ſuch towns deſerve the appellation, is Moco Moco. Marſden's Sumatra, p. 284.

INDRAPOUR *Point*, a cape on the W. coaſt of Sumatra. S. lat. 2° 10′. E. long. 100° 34′.

INDRAT, a town of Hindooſtan, in Dowlatabad; 23 miles N.W. of Beder.

INDRE, a river of France, which riſes about four miles N. N. W. from Bouſſac, in the department of the Creuſe; and joins the Loire at Rigny, between Saumur and Tours.

INDRE, one of the departments of the central region of France, formerly Lower Berri, in N. lat. 46° 45′, ſo called from the river which traverſes it from S.E. to N. W.; bounded on the N. by the department of the Loir and Cher, on the E. by that of the Cher, on the S. by the departments of the Creuſe and Upper Vienne, and on the W. by thoſe of the Vienne and Indre and Loire, about 54 miles from N. to S., and 45 from E. to W. Its capital is Chateauroux. It contains 362 ſquare leagues, and 207,911 inhabitants; it is divided into four diſtricts, *viz.* Iſſoudun, containing 39,341 inhabitants; Chateauroux, 75,588; La Chatre, 45,171; and Le Blanc, 47,811. Its cantons are 23, and communes 275. Its contributions amount to 1,652,606 francs; and its expences to 219,394 fr. 59 cents. The weſtern diſtrict of this department abounds in rocks, pools, and woods; but the other tracts, and in particular that on the right hand of the Indre, conſiſt of cultivated fields, vineyards, &c. yielding grain, wine, and paſtures; it has mines of iron, marble quarries, and mineral ſprings, &c.

Indre *and* Loire, one of the nine departments of the weſtern region of France, formerly Tourraine, in N. lat. 47° 10′, ſo called from the union of the two rivers: bounded on the N. by the department of the Sarte, on the E. by the departments of the Loire and Cher and the Indre, on the S. and S.W. by the department of the Vienne, and on the W. and N.W. by the department of the Mayne and Loire; about 50 miles from N. to S., and 45 from E. to W. Its capital is Tours. It contains 325 ſquare leagues, and 278,758 inhabitants. It is divided into three diſtricts, *viz.* Tours, including 128,635 inhabitants; Loches, 57,094; and Chinon, 93,029. Its cantons are 24, and communes 311. Its annual contributions amount to 2,868,779 francs, and its expences to 246,653 francs. This department, on account of its fertility, has been ſtyled the garden of France. The vallies and eminences near the borders of the large rivers are fertile, but at ſome diſtance are heaths and uncultivated tracts. The diſtrict lying between the Loire and the Cher is of a light and ſandy, but productive ſoil. The peninſula formed by the Indre, the Loire, and the Vienne, is noted for its fertility. A tract, called Brenne, is moiſt, but tolerably fruitful. The principal products are rye, barley, millet, wine, fruits, and paſtures. It has mines of iron, and mineral ſprings.

INDU, a name of the moon among Hindoo mythologiſts. This luminary is more commonly called Chandra, or Soma. (See Soma.) It has been ſurmiſed that the name India and Hindoo, words unknown in the ancient language of the country, may have been derived from Indu; but ſir William Jones and Mr. Wilkins diſcountenance ſuch an etymology. See Moor's Hindoo Infanticide, p. 171.

INDUCEMENT, in *Law*, is what is alleged as a motive or incitement to a thing; and it is uſed ſpecially in ſeveral caſes: *viz.* there is inducement to actions, to a traverſe in pleading, a fact or offence committed, &c. Inducements to actions need not have ſo much certainty as in other caſes: a general *indebitatus* is not ſufficient, where it is the ground of the action; but where it is only the inducement to the action, as in conſideration of forbearing a debt until ſuch a day; (for that the parties are agreed upon the debt) this being but a collateral promiſe, is good without ſhewing how due.

INDUCIARUM Petitio. See Petitio, and Emparlance.

INDUCTION, in *Logic* and *Rhetoric*, a conſequence drawn from ſeveral propoſitions, or principles, firſt laid down.

Thus the concluſion of a ſyllogiſm, is an induction made from the premiſes. See Syllogism.

Induction is alſo uſed for a kind of ſyllogiſm itſelf; being a medium between an enthymeme and a gradation, in regard it wants a propoſition (which, however, is underſtood,) as in the enthymeme; and abounds in aſſumptions (which yet are collateral, or of the ſame degree), which is the caſe in a gradation.

For inſtance; every terreſtrial animal lives, every aerial animal lives, every aquatic animal lives, and every reptile animal alſo lives; therefore every animal lives.

Here, it may be obſerved, are various aſſumptions, from the more general ſpecies of the animal kind collected into one; which this propoſition is ſuppoſed to precede; *e. gr.* that every animal is either terreſtrial, aerial, aquatic, or reptile.

Suidas reckons three kinds of induction: that juſt mentioned, which concludes or infers ſome general propoſition from an enumeration of all the particulars of a kind, he calls the *dialectic* induction.

The ſecond proceeds by interrogation, and concludes probably, or with a veriſimilitude; this is what the Greeks called ϖαραγογη, and was that which Socrates ordinarily made uſe of, as Cicero, in his Topics, and Quintilian have obſerved: and, therefore, called the *Socratic* induction. This, however, is a captious way of reaſoning: for while the reſpondent is not aware of what is deſigned to be inferred, he is eaſily induced to make thoſe conceſſions, which otherwiſe he would not. Beſides, it is not ſo well ſuited to continued as to interlocutory diſcourſes.

The third kind of induction is properly *rhetorical*; being a concluſion drawn from ſome example, or authority.

This is a very imperfect induction, all its force lying in a propoſition which is concealed, and which will hardly bear being expreſſed. Thus, he that ſays, Codrus died bravely for his country, therefore I muſt die bravely for my country; proves nothing, unleſs this propoſition be carried in mind, that I muſt do the ſame with Codrus. Again, Archimedes, and the other mathematicians, ſay, the ſun is much bigger than the earth; therefore, it muſt be owned, the ſun is much bigger than the earth. Where this propoſition is underſtood, *viz.* whatever Archimedes, and the other mathematicians, ſay, is true.

Induction is one of the four forms of reaſoning uſed by orators in confirmation; the other three are ſyllogiſm, enthymeme, and example, which laſt coincides with the third ſpecies of induction above enumerated.

Induction, in the *Engliſh Laws*, is uſually taken for the giving poſſeſſion to an incumbent of his church, by leading him into it, and delivering to him the keys, by the commiſſary, or biſhop's deputy, and by his ringing one of the bells.

When a clerk is inſtituted into a benefice, he is to exhibit his mandate from the biſhop to the archdeacon, or other perſon to whom it is directed, and hath a right thereby to be inducted into his living; and if he be refuſed induction, he hath a remedy both in the eccleſiaſtical court, and alſo an action of the caſe in common law, againſt the archdeacon. If the inductor, or perſon to be inducted, be kept out of the church, or houſe, by laymen, the writ *de vi laica* lies for the clerk, which is directed out of the chancery to the ſheriff of the county, to remove the force, &c. If another clergyman, preſented by the ſame patron, keep poſſeſſion, a ſpoliation is grantable out of the ſpiritual court, whereby the tithes, &c. ſhall be ſequeſtered, till the right be determined.

The archdeacon rarely inducts a clerk in perſon, but uſually iſſues out a warrant to the clerks and lettered perſons within the archdeaconry, impowering any of them to do it in his ſtead.

An induction made by the patron of the church is void; but biſhops and archdeacons may induct a clerk to the benefices of which they are patrons, by preſcription. No induction is neceſſary to a donative, where the patron, by donation in writing, puts the clerk in poſſeſſion without preſentation. 11 Hen. IV. cap. 7.

The uſual form and manner of induction is, for the inductor to take the clerk by the hand, and then to lay it on the key of the church, which muſt be then in the door, and to ſay, “ By virtue of this inſtrument, I induct you in the real, actual, and corporal poſſeſſion of the rectory or vicarage of ----, with all its fruits, profits, members, and appurtenances.”—This done, he opens the door, and puts the clerk in poſſeſſion of the church, and ſhuts the door upon him; who, after he hath tolled a bell (if there be any) to give the pariſhioners due notice and ſufficient certainty of their new miniſter, comes out, and deſires the inductor to indorſe a certificate of his induction on the archdeacon's warrant, and that all preſent will ſignify it under their hands. If the church-key cannot be had, it is ſufficient that the clerk lays hold of the ring of the door, the latch of the church, gate, &c. and, within two months after this, the clerk muſt read the thirty-nine articles, and all the ſervice of the day, both at morning and evening prayers, in the pariſh church of his benefice, and in the time of common prayer, and declare his aſſent and conſent: he muſt alſo then read the ordinary's certificate, in which is the declaration of his conformity, together with the ſame declaration, and of all this he muſt have two or three good witneſſes, who muſt ſign that they heard him do it, and be ready to atteſt it, *viva voce*, if required; and, within ſix months after induction, he muſt alſo take the oaths of allegiance, ſupremacy, and abjuration, at the quarter-ſeſſions, or in ſome one of the courts at Weſtminſter-hall.

Induction makes the parſon complete incumbent, and fixes the freehold in him. When a clerk is thus preſented, inſtituted, and inducted into a rectory, he is then, and not before, called in law, *perſona imperſonata*, or parſon imparſonee. 13 Eliz. c. 12. 13 and 14 C. II. c. 4. 1 Geo. ſtat. 2. c. 13. 9 Geo. II. c. 26. 23 Geo. II. c. 28.

INDULGENCE, in the *Romiſh Theology*, the remiſſion of a puniſhment due to a ſin, granted by the church, and ſuppoſed to ſave the ſinner from purgatory.

The Romaniſts found their indulgences on the infinite treaſure of the merits of Jeſus Chriſt, the Holy Virgin, and all the ſaints; which they ſuppoſe the church has a right of diſtributing by virtue of the communion of ſaints. See Supererogation.

Theſe indulgences were firſt invented in the eleventh century by popes Gregory VII. Victor, and Urban II. as a recompence for thoſe who went in perſon upon the wild enterprize of conquering the Holy Land. See Croisade

They were afterwards granted to thoſe who hired a ſoldier for that purpoſe, and in proceſs of time were beſtowed on ſuch as gave money for accompliſhing any pious works enjoined by the pope. In the beginning of the twelfth century, the biſhops, whenever they wanted a ſupply of money for their private pleaſures, or the exigencies of the church, recurred to the ſcandalous traffic of indulgences; and when the Roman pontiffs ſaw that immenſe treaſures were thus accumulated by the inferior rulers of the church, they thought proper to limit the powers of the biſhops in remitting the penalties impoſed upon tranſgreſſors, and aſſumed it, almoſt entirely, as a profitable traffic to themſelves. They began with granting a plenary remiſſion of all the temporal pains and penalties which the church hath annexed to certain tranſgreſſions; and then proceeded to aboliſh even the puniſhments which are reſerved in a future ſtate for the workers of iniquity.

The Roman jubilee, firſt inſtituted by Boniface VIII. A.D. 1300, carries with it a plenary, or full indulgence, for all the crimes committed therein.

The pope alſo grants bulls of plenary indulgence to ſeveral churches, monaſteries, and even to private perſons; and it is a frequent thing to have general indulgences for the time of the principal feaſts of a year. Their caſuiſts ſay that a plenary indulgence does not always prove effectual, for want of complying with the conditions whereon it was granted.

For the extirpation of heretics, it has been a common practice with the popes to grant indulgences. Thus Clement XII. “ That we may ſtir up and encourage the faithful to extirpate this ungracious crew of forlorn wretches, (the Cevenois, when in arms againſt Lewis XIV.) we fully grant and indulge the full remiſſion of all ſins, whatever they may be (relying upon that power of binding and looſing, which our Lord conferred upon his chief apoſtle), to all thoſe that ſhall liſt themſelves in this ſacred militia, if they ſhall happen to fall in battle.” See Absolution.

Julius II. had beſtowed indulgences on all who contributed towards building the church of St. Peter at Rome, and pope Leo X. in order to carry on this magnificent ſtructure, publiſhed indulgences, and a plenary remiſſion on the ſame pretences. Finding the project take, he granted the right of promulgating theſe indulgences in Germany, together with a ſhare in the profits ariſing from the ſale of them, to Albert, elector of Mentz, and archbiſhop of Magdeburg, who employed Tetzel, a Dominican friar, as his chief agent for retailing them; and he farmed out thoſe of other countries to the higheſt bidders, who, to make the beſt of their bargains, procured the ableſt of their preachers to extol the value of the ware: “ Happy times for ſinners,” ſays a modern writer, “ their crimes were rated, and the remiſſion of them ſet up by auction. The apoſtolic chamber taxed ſins at a pretty reaſonable rate; it coſt but ninety livres and a few ducats, for crimes which people on this ſide the Alps puniſhed with death.”

Theſe are ſpecified in a book of rates called the Tax-Book of the Holy Apoſtolic Chancery, firſt printed at Rome in the year 1514, and aſcribed by ſome to pope Innocent VIII. From a correct edition of this book, printed by L. Banck, profeſſor at Norkopin, in Gothland, in 1651, it appears that the price of abſolution for fornication, attended with the moſt heinous circumſtances, was ſix groſſi or groats; for a layman's murdering a layman, five groats; for laying violent hands on a prieſt, without ſhedding blood, nine groats; for committing inceſt, five groats; for a prieſt's keeping a concubine, ſeven groats; for forging the pope's hand-writing, ſeventeen or eighteen groats. See the Taxa S. Cancellariæ Apoſtolicæ, a L. Banck. Franequeræ, 1651, p. 126, &c. It was this great abuſe of indulgences, that contributed not a little to the firſt reformation of religion in Germany; wherein Martin Luther began firſt to declaim againſt the preachers of indulgences, and afterwards againſt indulgences themſelves: but ſince that time, the popes have been more ſparing in the exerciſe of this power; however, they afterwards carried on a great trade with them in the Indies, where they were purchaſed at two reals a-piece, and ſometimes more. See Reformation.

Indulgence, or *Indulto*, ſignifies alſo a ſpecial favour, or privilege, conferred either on a community, or a particular perſon, by the pope's bulls; in virtue whereof the party is licenſed to do or to obtain ſomething contrary to the intention and diſpoſition of the common laws.

There are two kinds of indultos: the one *active*, which conſiſts in a power of nominating and preſenting freely, and without reſerve, to benefices that are otherwiſe limited, and reſtrained by the laws of the apoſtolical chancery; ſuch are thoſe ordinarily granted to ſecular princes, cardinals, biſhops, &c.

Paſſive indultos conſiſt in a power of receiving benefices, and expectative graces; of which kind are thoſe of a parliament, of graduates, mandataries.

The indulto of kings is the power given them of preſenting to conſiſtorial benefices, either by treaty, by favour, or ſpecial privilege.

The indulto of cardinals is a licence for holding regular as well as ſecular benefices, and for diſpoſing of benefices *in commendam*, or continuing them, &c.

Indulto of parliament is a right of privilege formerly granted to the chancellor, preſidents, counſellors, and other officers in the parliaments of France, to obtain a benefice of the collator, upon the king's nomination directed to him. This was a kind of advowſon, or patronage, belonging to the French king; the indulto being a mandate, or grace, by which he was permitted to name to any collator he pleaſed a counſellor, or other officer of parliament, on whom the collator ſhould be obliged to beſtow a benefice: ſo that the right of the indulto reſided radically in the king, the officers being only the objects thereof.

INDULPHUS, in *Biography*, the ſeventy-ſeventh king of Scotland, began his reign in the year 959. The early years of his reign were peaceable and proſperous, but afterwards his kingdom was invaded ſeveral times by the Danes, who were enraged againſt him for making an alliance with the Engliſh. Their firſt deſcent was upon Eaſt Lothian, whence they were ſoon expelled, but croſſed over to Fife. Here they were defeated, and driven out, and ſo well had Indulphus taken care to guard the coaſts, that they could find no other opportunity of invading the country; till, having thrown the Scots off their guard, they made good their landing in Banffſhire. Here Indulphus attacked them in their camp, and drove them towards their ſhips, but was killed in an ambuſcade, into which he fell during the purſuit.

INDULTO, in *Commerce*, denotes a duty, tax, or cuſtom paid to the king of Spain for all ſuch commodities as are imported from the Weſt Indies in the galleons.

INDURATING, a term applied to ſuch things as give a harder or firmer conſiſtence to others, either by the greater ſolidity of their particles, or by diſſipating the thinner parts of any matter, ſo as to leave the remainder harder.

INDURATION *of* STRATA, in *Geology*, denotes the change which all the maſſes of the earth evidently have undergone ſince they were depoſited in their preſent ſituation in a fluid or plaſtic ſtate; under the article HARDENING *of Strata*, we have noticed ſome of the facts and theories on this ſubject, to which we beg to refer.

INDUS, or SINDÉ, or, according to the proper Sanſcrit name *Sundhoo*, under which name it was not unknown to the Romans (*Indus incolis Sindus appellatur*, Pliny, l. vi.) a celebrated river of Aſia, which is formed of about 10 principal ſtreams, that deſcend from the mountains of Perſia, Tartary, and Hindooſtan, on the N.E. and N.W.; all which ſtreams, uniting near Moultan in Hindooſtan, form this famous river. The Ayin Acbaree ſays, the Sindé, according to ſome, riſes between Caſhmere and Caſhgar, whilſt others place its ſource in Khatai, meaning probably Koten, the Chatæ of Ptolemy, and not China. It is clear, however, that the people of Hindooſtan conſider the north-eaſtern branch as the true Sindé, though the ancients ſeemed to have reckoned otherwiſe; for Pliny ſays "in jugo Caucaſi montis, quod vocatur Paropamiſus, adverſus Solis ortum effuſus." The emperor Baber, indeed, applies the name of Sindé to one of its weſtern branches, that ſprings near Bamian, but he appears to differ in this particular from the reſt of his countrymen; for the name of Nilab, which was applied to the river that ran by the ſcite of Attock (long before that city was founded), was applied alſo to the ſame river, in its courſe through Little Thibet; and Nilab is ſynonymous with Sindé. (See NILAB.) The Indus, under the name of Nilab, paſſes through the country of Little Thibet; and its head muſt be on the weſt of the great ridge of mountains called by the ancients Imaus, becauſe on the eaſt of it, the rivers all run in a direction oppoſite to that of the Indus. About 20 miles above Attock, the periodical rains, which fell on the northern mountains, having conſiderably ſwelled the river, its breadth was about $\frac{3}{4}$ of a mile; its courſe rapid and turbulent, and its water extremely cold, with a great quantity of black ſand ſuſpended in it. At Attock the Indus is joined by the Cabul, and very conſiderably increaſed by it, ſo that from Attock downwards to Moultan, or to the conflux of the Panjab waters, where it has obtained the name of Attock, it is no longer fordable; below that point it is called Soor, or Shoor, until it divides itſelf into a number of branches near Tatta, where the principal branch takes the name of Mekran. This river, however, when ſpoken of generally, is called Sindé; although particular parts of it are known by different names. The Indus, and its branches, admit of an uninterrupted navigation from Tatta, the capital of Sindy, to Moultan and Lahore, for veſſels of near 200 tons. About 170 miles from the ſea, by the courſe of the river, the Indus divides into two branches, of which the weſternmoſt is by much the largeſt. This branch, after a courſe of about 50 miles to the S.W., divides into two more; the ſmalleſt of which runs in a W.S.W. courſe, to Larry-Bunder and Dacraway; and the largeſt, taking the name of Ritchel river, runs in a more ſouthwardly courſe to the town or village of Ritchel, on the ſea-coaſt. The other principal branch is that which bounds the eaſtern ſide of the Superior Delta; ſeparating, as we have ſaid, about 170 miles from the ſea. It is ſmaller than the Ritchel river, but larger than that of Larry-Bunder, and according to circumſtances and report, it opens into the mouth of the gulf of Cutch, nearly oppoſite to Jigat point; its courſe being ſomewhat to the eaſtward of ſouth. Major Rennell infers from various circumſtances, that the Delta of the Indus (ſee DELTA) is about 150 Britiſh miles in length along the ſea-coaſt, and about 115 in depth, from the place of ſeparation of the ſuperior branches of the river, to the moſt prominent point of the ſea-coaſt. The lower part of this Delta is interſected by rivers and creeks in almoſt every direction, like the DELTA *of the Ganges*, but without trees; the dry parts being covered with bruſhwood, and the remainder, being by much the greateſt part, being noiſome ſwamps, or muddy lakes. The upper part of the Delta is well cultivated, and yields abundance of rice. This Delta is ſet apart for the breeding of camels, anſwering this purpoſe by means of the tender parts of its bruſhwood, which ſerves them for fodder. The breadth of the Ritchel branch is eſtimated at one mile, juſt above the tide; and at Tatta, at only half a mile. It is certain that the Indus is very conſiderably leſs than the Ganges. The velocity of its current is eſtimated at four miles per hour in the dry ſeaſon; but this is ſuppoſed by Rennell to be over-rated. The courſe of the Indus river is ſtated by major Rennell at (probably) $6\frac{3}{4}$, that of the Thames being 1. This ingenious geographer mentions the moveable towns or villages that are ſituated on the banks of the river, noticed by Nearchus and the Ayin Acbaree; ſome of which are the habitations of fiſhermen, and others of graziers; which are continually changing their poſitions like a camp. Few rivers abound more with fiſh than the Indus does; and among theſe are ſome very delicious ſorts. The mouths of the

Indus are comprehended between N. lat. 23° 20′ and 24° 40′.

INDUSTRY, *Fruits of.* See FRUITS.

INEADA, in *Geography*, a town of European Turkey, in Romania; 56 miles E.N.E. of Adrianople.

INEQUALITY *of Natural Days.* See EQUATION.

INEQUALITY, *Optical.* See OPTICAL.

INERT *Vegetable Matter*, in *Agriculture*, is a term lately given to that ſort of vegetable matter which, by long and frequent expoſure, has been ſo ſaturated and combined with the oxygen or pure air of the atmoſphere, as to be rendered in a great degree inſoluble. The ſurface of peat moſſes, and the mould of ſuch ſoils as have been much expoſed to the action of pure air, by fallowing, are ſuppoſed to be rendered inert in this way by the author of the "Connection of Chemiſtry with Agriculture." See PEAT.

INERTIÆ VIS. See VIS *Inertiæ.*

INESCUTCHEON, in *Heraldry*, a ſmall eſcutcheon borne in a larger one, as part of ſome other coat. See ESCUTCHEON.

Guillim confines the name to an eſcutcheon borne ſingle in the feſs point or centre.

This is alſo ſometimes called an *eſcutcheon of pretence.*

He who marries an heireſs, bears her coat of arms on an *ineſcutcheon*, or *eſcutcheon of pretence*, in the middle of his own coat.

Modern heralds apply the name ineſcutcheon to thoſe ſmall eſcutcheons, ſeveral of which are borne in a large one.

INESERRHA, in *Geography*, a town of Africa, in Sennaar; 10 miles E. of Gieſſien.

IN ESSE is applied to things which are actually exiſting.

Authors make a difference between the thing *in eſſe*, and a thing *in poſſe*. A thing that is not, but may be, they ſay, is *in poſſe*, or *potentia*; but a thing apparent and viſible, they ſay, is *in eſſe*, that is, it has a real being *eo inſtanti*; whereas the other is caſual, and at beſt but a poſſibility.

INEVERAM, in *Geography*, a town of Hindooſtan, in the circar of Rajamundry; 32 miles S.E. of Rajamundry.

INFALISTATIO, an ancient puniſhment of felons, by throwing them among the rocks and ſands, cuſtomarily uſed in port-towns. It is the opinion of ſome writers, that *infaliſtatus* did imply ſome capital puniſhments, by expoſing the malefactor upon the ſands till the next tide carried him away; of which cuſtom, it is ſaid, there is an old tradition. However, the penalty ſeems to take its name from the Norman *faleſe*, or *faleſia*, which ſignified not the ſands, but the rocks and cliffs adjoining, or impending on the ſea-ſhore. "Commiſit feloniam ob quam fuit ſuſpenſus, utlagatus, vel alio modo morti damnatus, &c. vel apud Dover infaliſtatus, apud Southampton ſubmerſus, &c."

INFALLIBLE, from *in*, taken privatively, and *fallo*, I *deceive*, that which cannot deceive or be deceived.

Upon this term ſtands one of the principal heads of controverſy between the Reformed and the Catholics; the latter of whom maintain, that the church, aſſembled in general council, is infallible; which the former deny.

The Jeſuits, in their diſputes with the Janſeniſts, have expreſsly aſſerted that Jeſus Chriſt hath given to all popes whenever they ſhall ſpeak *è cathedra*, the ſame infallibility which he had, both in matters of right and fact.

The principal reaſons alleged for the infallibility, are drawn from the promiſes of Chriſt, from the obſcurity of the ſcriptures, the inſufficiency of private judgment, and the neceſſity there is of ſome infallible judge for the deciſion of controverſies.

The infallibility of the pope is a doctrine of a late ſtanding, and has not been entirely acquieſced in, even in their own communion, and altogether rejected by the Gallican church. See POPERY.

INFAMOUS, derived from *in*, and *fama*, *fame*, *report*, in the ordinary uſe of the word, ſignifies ſomething notoriouſly contrary to virtue, or honour.

Aulus Gellius uſes the word *infames materias*, for what we ordinarily call *paradoxes*, *i. e.* diſcourſes remote from the common opinion; propoſitions that appear oppoſite to truth, &c. as the elogy of Therſites, the praiſe of a quartan ague, &c.

INFAMOUS, in *Law*, denotes a perſon or thing, which is of no repute, or eſteem, in the world.

There are two kinds of infamy: ſome perſons being infamous as having been noted by the laws, or ſtigmatized by public judgment.

Infamy, which extends to forgery, perjury, groſs cheats, &c. diſables a man to be a witneſs or juror: but a pardon of crimes reſtores a perſon's credit to make him a good evidence. Judgment of the pillory makes infamy by the common law, but by the civil and canon law, if the cauſe for which the perſon was convicted was not infamous, it infers no infamy.

Others are held infamous, by the exerciſe of ſome ſcandalous profeſſion; as a catchpole, a merry-andrew, a hangman, an informer, &c.

Heretofore there were crowns of infamy given, by way of puniſhment, to criminals: they were made of wool.

INFANCY. See INFANT.

INFANT, in a *Law ſenſe*, a perſon under the age of one-and-twenty years, whoſe acts are in many caſes either void or voidable. (See AGE.) All gifts, grants, &c. of an infant, which do not take effect by delivery of his hand, are void; and if made to take effect by delivery of his own hand, are voidable by himſelf and his heirs; and thoſe who ſhall have his eſtate.

Although an infant, under 21, can make no deed which is not afterwards voidable; yet in ſome caſes he may bind himſelf apprentice by deed indented, or indentures for ſeven years (ſtat. 5 Eliz. c. 4. 43 Eliz. c. 2. Cro. Car. 179); and he may by deed or will appoint a guardian to his children, if he has any. Stat. 12 Car. II. c. 24.

By the cuſtom of London, an infant, unmarried, and above the age of fourteen, may bind himſelf apprentice to a freeman of London, by indenture, with proper covenants, which ſhall be binding.

An infant may bind himſelf to pay for neceſſaries, as meat, drink, apparel, phyſic, and learning, but not by bond with penalty; though a bill for neceſſaries, without a penalty for the very ſum due, it is ſaid, will bind him. Infants are not obliged to pay for clothes, unleſs it be averred for their own wearing: and that they were convenient and neceſſary for them to wear according to their degree and eſtate. An infant may buy, but cannot borrow money to buy neceſſaries; for the law will not truſt him with neceſſaries, but at the peril of the lender, who muſt lay it out for him in neceſſaries, or ſee it thus laid out.

An infant has been adjudged of age the day before his birth-day; for the law will not make a fraction of a day; therefore where a perſon was born the third of September, and the ſecond of September, twenty-one years after, he made his will, it was held good, and that he was then of age to deviſe his lands. And it is ſaid ſuch will ſhall take effect, though the deviſor dies by ſix at night of that day.

An infant eight years of age, or upwards, may commit homicide, and be hanged for it, if it appear, by any other act, that he had knowledge of good and evil; for here *malitia ſupplebit ætatem:* yet Coke on Littleton, sect. 405, ſays, "An infant ſhall not be puniſhed till the age of fourteen;" which, according to him, is the age of diſcretion.

But this depends on the degree of judgment which he poſſeſſes. If an infant be *infra annos infantiæ, viz.* ſeven years old, he cannot be guilty of felony, whatever circumſtances proving diſcretion may appear. See Age, in *Law*, Executor, Guardian, &c. See alſo Rape.

An infant *en ventre ſa mere*, or in the mother's womb, is capable of having a legacy, or a ſurrender of a copy-hold eſtate made to it. It may have a guardian aſſigned to it (ſtat. 12 Car. II. c. 24.); and is enabled to have an eſtate limited to his uſe, and to take afterwards by ſuch limitation, as if it were then actually born (ſtat. 10 & 11 W. III. c. 16.); and in this point the civil law agrees with our's. Though infants cannot alien their eſtates, yet infant truſtees or mortgagees are enabled to convey, under the direction of the court of chancery or exchequer, or other courts of equity, the eſtates they hold in truſt or mortgage, to ſuch perſon as the court ſhall appoint. By the cuſtom of gavel-kind, an infant, at the age of fifteen, is reckoned at full age to ſell his lands; and by cuſtom, in ſome places, an infant ſeiſed of land in ſocage, may, at the ſame age, make a leaſe of years, that ſhall bind him after he comes of age.

An infant, who has an advowſon, may preſent to the benefice when it becomes void. (Co. Litt. 172.) An infant is capable of inheriting, and may alſo purchaſe lands, but his purchaſe is incomplete; for, when he comes to age, he may either agree or diſagree to it, without alleging any reaſon; and ſo may his heirs after him, if he dies without having completed his agreement. (Co. Litt. 2.) And in caſe any infant bargain and ſell his land by deed, indented and inrolled, yet he may plead non-age.

If an infant grants leaſes for a term of years, he may, at his full age, either confirm the leaſe, or bring treſpaſs againſt the leſſee for the occupation. Alſo a leaſe granted to an infant, may be avoided by waiving the land before the rent-day expreſſed therein. However, infants are bound in all acts of neceſſity; as preſentations to benefices, admittances and grants of copy-hold eſtates, aſſenting to legacies, and conditions annexed to lands, whether the eſtate comes by grant or deſcent. If an infant be the defendant in an action, the plaintiff ſhall have ſix years for commencing his action, after the defendant comes of age; and an infant, who is a plaintiff, has alſo ſix years after he comes of age, to ſue by the ſtatute of limitation.

Infants, *Diſeaſes of*, in *Medicine*. When the extreme delicacy and tenderneſs of every part of the ſtructure of the infant frame is conſidered, as well as the extraordinary revolution, which it ſuddenly undergoes, in paſſing from its vegetating ſtate, as it were, in the uterus, to that of a breathing animal, it muſt be obvious that a thouſand circumſtances, which make no impreſſion on the adult frame, will powerfully influence that of the infant; and that the utmoſt care will be required to ſhield it from numerous cauſes of diſeaſe, from the moment of its birth. To the neglect of theſe circumſtances, or to their inability of attending to them, the great mortality that occurs among the children of the poor, in large cities, is perhaps chiefly to be aſcribed. But this was formerly much augmented, among all ranks, by the abſurd and unnatural interference of art, which was apparently dictated by a notion that the inſtincts and intimations of nature were to be oppoſed, as of the moſt baneful tendency. Fortunately the more rational ſyſtem of following theſe intimations, as the beſt guides to health, has generally ſuperſeded that abuſe; and it will only be requiſite for us here to ſpeak of ſome of the accidents attendant on birth, of the more frequent connate imperfections of ſtructure, and of the diſeaſes peculiarly belonging to the period of infancy and childhood.

Recovery of *ſtill-born or weakly infants.* Dr. Hamilton obſerves, that the occaſional recovery of ſtill-born children, under circumſtances where experience alone could have encouraged any hopes, ought to teach practitioners the importance of employing, with patience and attention, the means conducive to that purpoſe. If there is no pulſation in the umbilical cord, the infant ſhould be inſtantly ſeparated from the mother, the cord being tied by a ſlip knot, and the body immerſed in warm water. The lungs ſhould be then diſtended with air, by means of a bag of elaſtic gum, or a common ſyringe, (the pipe of which is to be inſerted into one noſtril, while the other and the mouth are carefully cloſed,) and again emptied by gentle preſſure on the breaſt. In this way an alternate diſtention and compreſſion of the lungs ſhould be continued for ſome time. Should the action of the heart be now perceived, the ſame means are to be continued, until the infant exhibit the uſual marks of beginning reſpiration, when the artificial diſtention of the lungs is to be only occaſionally repeated, and all preſſure on the breaſt is to be avoided. But if, notwithſtanding theſe means, the pulſation of the heart be not reſtored, the infant ſhould be taken out of the warm water, placed before the fire, carefully rubbed, and then wrapped in warm flannel. A glyſter, conſiſting of a table-ſpoonful of ſpirits, and two or three table-ſpoonfuls of warm water ſhould then be adminiſtered, and the temples, noſtrils, and teguments of the face round the mouth, ſhould be gently touched with a feather, dipped in vitriolic æther, or ſpirits of hartſhorn. But, ſecondly, if the pulſation in the cord of a ſtill-born child is diſtinct and ſoft, and the infant has the natural appearance, ſo long as the placenta remains attached to the uterus, the child ought not to be ſeparated from the mother. The body ſhould be carefully wrapped in warm flannel, the noſtrils and fauces ſhould be touched with a feather dipped in vitriolic æther, and a little ſpirits rubbed on the breaſt. If the after-birth become detached, (which is known by the lengthening of the cord,) the child muſt be immediately ſeparated, and the above means employed. Should the proceſs of breathing commence after theſe means have been uſed for a few minutes, nothing elſe is to be done than keeping the infant warm, with its face freely expoſed to the air. But ſhould this not take place, the lungs are to be diſtended and again compreſſed, as in the firſt caſe. See Prof. Hamilton's Hints on the Diſeaſes of Infants, &c.

Although alive when born, the infant, in ſome inſtances, lives only a ſhort time. If the lips be pale, and the pulſation in the heart very feeble or ſlow, it may be ſuſpected that this originates from ſome cauſe which is not cognizable to the ſenſes. On the ſuppoſition that it ariſes from a deficiency of vitality, ſtimulants have been applied to the ſurface, as a little brandy, or ſpirits of hartſhorn, rubbed on the ribs and ſpine, &c.: and ſuch means have occaſionally proved efficacious, though in the majority of caſes they fail. When the extremities are of a purple or blueiſh colour, and the breathing is impeded or unnatural, it is generally found that there is a defect in the heart or lungs, which is beyond the power of any remedy.

§ 1. *Connate Imperfections.*—Children are not always born in a ſtate of perfection in reſpect to the ſtructure of their bodies; for ſometimes they have deficient, ſuperfluous, or miſplaced parts, natural paſſages cloſed, and various marks on the ſurface. Many of theſe imperfections admit of no remedy; while others may be eaſily rectified. The following are thoſe which are moſt frequently met with.

Fiſſures in the lips not only conſtitute a remarkable deformity, but commonly prevent the child from ſucking. They appear under various forms. Sometimes the fiſſure exiſts only in one lip, generally the upper one, and is occaſioned merely by a diviſion of the ſoft parts: in other caſes, there is a conſiderable loſs of ſubſtance between the divided parts: in ſome inſtances, again, there are two fiſſures in one lip, or both lips are affected: and in others, the fiſſure is not confined to the lips, but extends along the roof of the mouth. All theſe different ſpecies of the ſame deformity receive the general name of *hare-lip;* which ſee.

The *tongue* is naturally bound down to the lower part of the mouth by a membranous cord, to prevent it from too great a degree of motion. Sometimes, however, the cord fixes it ſo much, that the infant cannot ſuck, in which caſe it is commonly ſaid to be *tongue-tied.* Women very often imagine that their children have this defect, when it does not really exiſt: and perhaps one inſtance of it does not occur in ſeveral hundreds of thoſe that are born. The diſeaſe may be always diſcovered by putting a finger gently into the child's mouth; for if he be able to graſp it, as he would do the nipple in ſucking, or if the tip of the tongue appear diſengaged, the membrane does not require to be cut. The operation of dividing the *frænum,* trifling as it may appear, requires ſome caution, in order to avoid wounding the ſublingual veins, and cutting too deep; for in the firſt caſe, a fatal hæmorrhage may enſue; and in the ſecond, if the tongue is looſened too much, the tip may be turned back, and cloſe up the throat; an accident that muſt ſoon occaſion death. It may be diſcovered by the threatening ſuffocation or convulſions, and by the introduction of the finger into the mouth, by which alſo the tongue may be pulled back, and the conſequences avoided. This, however, is a very rare accident: it has been abſurdly called "ſwallowing the point of the tongue." See Underwood on the Diſeaſes of Children, vol. ii. p. 17. 5th edit.

The *natural paſſages,* eſpecially the *anus, vagina,* and *urethra,* are ſometimes *imperforate,* preventing altogether, or in great part, the uſual excretions. In ſome caſes, a collection of mucus alone proves the obſtacle; but in others, membranous ſubſtances cloſe up the paſſages, in which laſt inſtances, an operation will be requiſite to open the parts, which muſt be performed by a ſkilful ſurgeon. In reſpect to the vagina, Dr. Underwood obſerves that he never found the external parts totally imperforate, there being always a ſmall opening at the *meatus urinarius:* but the aperture to the vagina itſelf ſometimes requires to be opened, either by the point of a lancet, or by the fingers only, which is generally eaſily effected, there being always a *raphè,* or line, where the natural opening ſhould be. The anus is ſometimes cloſed only by a thin membrane, ſo that the day after birth the meconium may be diſtinctly felt, and in a manner ſeen ſhining through it. A ſlight puncture with a lancet, and paſſing a bougie or the point of a finger into the bowel for two or three days afterwards, is ſufficient to remove this impediment. But more commonly the imperforate anus is a melancholy caſe, allowing of no effectual remedy, as the gut often terminates in a cul-de-ſac: ſo high as not to be reached. The imperforate penis is not quite ſo common a caſe; but is not unfrequently ſuſpected, when the aperture of the paſſage is merely ſtopped up by a little mucus. Under ſuch circumſtances, waſhing the part with warm milk and water, or at moſt a little aſſiſtance with a ſmall probe, or any ſuch blunt-pointed inſtrument, will be ſufficient to open the paſſage. When the urethra is perfectly open nearly to the extremity, as often happens, it is neceſſary only to make a ſmall aperture with a lancet, or a fine trocar, and to keep the part open by the occaſional introduction of a ſlender bougie.

Tumours about the back-bone of infants are always dangerous. If they be ſoft, partly tranſparent, and obviouſly connected with the ſpine, conſtituting the diſeaſe called *ſpina bifida,* or *hydrorachitis,* they moſt generally prove fatal ultimately; although in ſome inſtances, the progreſs to that event has been very ſlow, the child having lived to the thirteenth year. Fortunately, however, it more commonly terminates within a few months after birth: where it is protracted, the individual is in a miſerable ſtate, being paralytic in his lower limbs, &c.

Retention of the Meconium.—The meconium is that black, viſcid matter, which every infant diſcharges from the inteſtines for the firſt two or three days after birth; and many complaints have been aſcribed to the undue retention of it, and conſequently a great variety of purgative medicines have been recommended to be given, almoſt as ſoon as the child is born, with a view to expel it. But experience has taught that the natural evacuant of this matter is the firſt milk of the mother, which is ſlightly laxative in its properties: the infant, therefore, ſhould be put to the breaſt as ſoon after birth as the ſituation of the mother will allow. The pernicious practice of giving infants purging medicines, Dr. Hamilton remarks, as ſoon as they are born, cannot be too much reprobated; for the retention of the meconium for ſome hours after birth certainly produces leſs inconvenience than is occaſioned by the acrimony of the ſubſtances which the child is often forced to ſwallow. The moſt ſimple artificial means, he adds, for removing this matter, are Liſbon ſugar diſſolved in water, or a ſolution of manna. Where theſe fail, a teaſpoonful of cold drawn caſtor oil is to be given.

Jaundice, or, as the nurſes term it, the *yellow gum,* is among the diſeaſes which take place within a few days after birth. It is preceded by drowſineſs, and diſinclination to ſuck, and is ſoon diſcovered by the univerſal yellowneſs of the ſkin. Sometimes the whites of the eyes appear yellow for a day or two before the other ſymptoms appear: the tinge of the ſkin is ſeldom deep, and the diſeaſe is more readily removable than the jaundice of adults; but caſes are occaſionally met with, where the colour of the ſkin is of a dark yellow, the infant moans conſtantly, and convulſions follow, which at laſt deſtroy life. In regard to the treatment of this diſeaſe, if the child ſeem to ſuffer no uneaſineſs, although its ſkin be quite yellow, and if his bowels be open, it will be unneceſſary to adminiſter any medicines. But if he be unable to ſuck, and have a diſpoſition to conſtant ſleep, active meaſures ſhould be adopted. Theſe conſiſt principally in evacuating the viſcid matter, which probably clogs up the biliary ducts. An emetic of ipecacuan, and briſk laxatives, as of rhubarb, or frequent doſes of a ſolution of manna, will then be found neceſſary, and their effects may be much promoted by the warm bath. When violent colic pains or convulſions accompany the yellow gum, there is reaſon to fear that the liver is diſeaſed, and little can be expected from any remedy.

The *thruſh,* ſore mouth, or *aphthæ,* is ſo common a diſeaſe in early infancy, that it has been imagined to be a ſalutary effort of nature to expel ſome hurtful matter from the ſyſtem, which might otherwiſe be productive of many complaints at a future period. This opinion, however, is merely a vulgar prejudice, founded neither on reaſon nor experience. *Aphthæ* appear to be connected with a deranged condition of the alimentary canal, and ſeem to ariſe moſt frequently from the too early or too liberal uſe of ſpoon-meat, or improper food : but other cauſes occaſionally produce it, ſuch as expoſure to cold, damp weather, &c. In the treatment of this complaint, Dr. Hamilton affirms, that the great object hould be to promote its natural progreſs, and to counteract he effects of the acrimony of the ſaliva. The early uſe of timulant applications, ſuch as gargles of port-wine and borax, force off the ſpots before they have undergone the natural changes, and by their irritation keep up the diſeaſe. But the proper objects may be obtained by putting frequently into the infant's mouth a tea-ſpoonful of a liquor, prepared by mixing with the white of an unboiled egg, three able-ſpoonfuls of cold water, and a little refined ſugar, by prohibiting all ſpoon-meat, and by frequently duſting he natural paſſages with prepared calamine or tutty powder. When the ſpots become yellow, the borax may be llowed. It is to be mixed with eight or ten times its weight of powdered ſugar or of honey, or it may be diſſolved in fig-tea in the ſame proportion. If the ſpots grow ivid, bark and port-wine ſhould be uſed as a gargle, while he infant is ſupported by means of ten or twelve parts of warm cow's milk, mixed with one part of ſherry wine. The ſame kind of nouriſhment is neceſſary in caſes, where, rom the extenſive incruſtation over the tongue and cheeks, he infant is incapable of ſucking, which often happens for day or two. See APHTHÆ.

§ 2. *Diſeaſes of the Skin.*—Two diſeaſes, of a febrile naure, connected with a morbid condition of the ſkin, have een deſcribed by writers on the diſorders of infancy, which merit attention. They are almoſt unknown, however, exept to the phyſicians of lying-in hoſpitals, as they have eldom occurred in the private houſes of individuals. The rſt of theſe is eryſipelatous inflammation of the ſkin, called y Dr. Underwood *eryſipelas infantile*, which ordinarily ccurs within a few days after birth, and ſometimes at a ter period. It ſeizes the moſt robuſt, as well as delicate, hildren ; making its attacks in a very ſudden manner, and roceeding rapidly in its courſe. It moſt commonly apears firſt on the toes or fingers, which look ſwelled and lue, as if from cold ; but in the more violent forms, it egins about the pubes, and extends upwards on the belly, nd down the thighs and legs ; or ſometimes it commences the neck, when it is equally dangerous. It appears, ineed, to be always moſt dangerous when it ſeizes or ſpreads the body, and moſt mild when confined to the extreities. Suppuration and gangrene are occaſionally the conequences ; but even where neither of theſe events takes place, may terminate fatally from effuſion into ſome of the caviies, or from the inflammation extending to the contents of the domen, glueing the parts together, and throwing out upon eir ſurface an exudation of coagulable lymph. On the hole, the treatment of this infantile *eryſipelas* has too freuently proved unſucceſsful. The uſe of ſaturnine lotions nd poultices, on the firſt appearance of the inflammation, emed to check its progreſs at firſt ; but it was ſoon found ſpread, and to terminate in a fatal ſuppuration or morfication. A more cordial plan of treatment has been tended with a ſomewhat greater degree of ſucceſs ; and e application of external ſtimulants, ſuch as linen comreſſes wrung out of camphorated ſpirit, has in ſome caſes ecked the inflammation. The bowels ſhould be kept open, and the free admiſſion of pure air enforced : indeed, it is probable that, in proportion to the effectual ventilation employed, the occurrence of the diſeaſe will be diminiſhed, and its violence, when it does appear, mitigated.

Another affection of the ſkin, accompanied by fever, and occurring under ſimilar circumſtances, has been called by Dr. Underwood, who was one of the firſt to deſcribe the diſeaſe, the *ſkin-bound diſeaſe*. This does not happen invariably, like the preceding complaint, within a ſhort time after birth ; for it has been known to attack infants above ſix months old. It is uſhered in with violent fever, with coldneſs of the limbs, oppreſſed breathing, and almoſt conſtant moaning. The ſkin is of a yellowiſh-white colour, reſembling ſoft wax in its appearance, and not only thickened and hardened, but evidently unyielding ; the cellular membrane is fixed in ſuch a manner that it will not ſlide over the ſubjacent muſcles, not even on the back of the hands, where it is uſually very looſe and pliable. This ſtricture often extends over the whole body ; but the ſkin is peculiarly rigid in the parts about the face, and on the extremities. The child is always cold, and whatever number of days it may ſurvive, has conſtantly the appearance of being in a dying ſtate. The ſtools are of a clayey colour and conſiſtence ; and the diſeaſe ſeems to be much connected with a diſorder of the chylopoietic organs, eſpecially of the liver. The free uſe of laxatives, together with the warm bath, and ſome cordial medicines, appears to have been occaſionally ſucceſsful ; but in general, where the progreſs of the diſeaſe has not been arreſted in the commencement, it has terminated fatally.

The moſt common affections of the ſkin, however, that occur in early infancy, are unaccompanied by fever, are productive of only ſlight inconvenience, without danger, and conſiſt principally of certain raſhes, or eruptions of papular or puſtular ſpots. The moſt common of theſe is a papular eruption, which appears under a variety of forms, and has been called the *gum*, or technically *ſtrophulus*. Dr. Willan has diſtributed thoſe varieties of appearance under five heads : the moſt frequent of which is the *red gum* (or *red gown*, as it was formerly denominated, probably becauſe the child's ſkin, thus variegated, ſomewhat reſembles a piece of red printed linen), the ſtrophulus *intertinctus*. The *papulæ*, or pimples, in this affection, riſe ſenſibly above the level of the cuticle, are of a vivid red colour, and commonly diſtinct from each other : their number and extent vary much in different caſes. They appear moſt conſtantly on the cheeks, fore-arm, and back of the hand, but are ſometimes diffuſed over the whole body. This eruption has not in general any tendency to become puſtular, but uſually terminates in ſcurf, or exfoliations of the cuticle. Its duration, however, is very uncertain : the papulæ and ſpots ſometimes remain for a length of time without any alteration ; ſometimes diſappear and come out again daily : but for the moſt part, one eruption of them ſucceeds another, at longer intervals, and with more regularity. The red gum occurs chiefly within the two firſt months of lactation : it is not always accompanied or preceded by any diſorder of the conſtitution, but appears occaſionally in the ſtrongeſt and moſt healthy children. In many inſtances, it is connected with a weak irritable ſtate of the alimentary canal, and conſequent indigeſtion. For if it be, by any means, ſuddenly repelled from the ſurface, diarrhœa, vomiting, ſpaſmodic affections of the bowels, and often general diſturbance of the conſtitution, ſucceed ; but as ſoon as it reappears, thoſe internal complaints are wholly ſuſpended. Dr. Armſtrong and others have particularly noticed this reciprocation, which makes the *red gum* at times a diſeaſe of ſome importance, though, in its uſual form, it is not thought to be in any reſpect dangerous. On their remarks a neceſſary caution is founded, not to expoſe infants to a ſtream of very cold air, nor to plunge them unſeaſonably in a cold bath; the moſt violent and even fatal ſymptoms having often been the conſequence of ſuch imprudent conduct. Little need be ſaid in regard to the treatment of the *red gum:* the common mild appearance of it, being conſiſtent with a healthy ſtate of all the functions of the body, requires no medicinal application. It is, however, adviſable to keep the ſkin clear from *ſordes*, and to promote equable perſpiration. This may be done beſt by daily ablutions with tepid water, which prove uſeful in moſt cutaneous diſorders, and will be found of conſiderable importance with reſpect to the general health of the infant.

The other varieties of *ſtrophulus*, mentioned by Dr. Willan, are two, the *S. albidus*, or *white gum*, which differs from the former merely in the appearance of its papulæ, which conſiſt of a number of minute, whitiſh ſpecks, a little elevated, and ſometimes, though not conſtantly, ſurrounded by a ſlight redneſs, occurring chiefly on the face, neck, and breaſt, and being more permanent than the papulæ of the *red gum*. 3. *S. confertus*, or *rank red gum*, ſometimes alſo called the *tooth-raſh*, which uſually takes place about the fourth or fifth month after birth, on the cheeks and ſides of the noſe, extending ſometimes to the forehead and arms, but rarely to the trunk of the body, and accompanying the ſtate of dentition; and in the ſeventh or eighth month aſſuming a ſomewhat different form, appearing in one or two large irregular patches, of a high red colour, on the arms, ſhoulder, or neck. 4. *S. volaticus*, which is characteriſed by ſmall, circular patches, or cluſters of papulæ, ariſing ſucceſſively on different parts of the body, continuing red, with a little heat or itching, for about four days, when they turn brown, and begin to exfoliate; the ſucceſſive patches, however, not ceaſing to appear in leſs than three or four weeks. And, 5. Strophulus *candidus*, in which the papulæ are larger than in any of the foregoing ſpecies, have no inflammation round their baſe, and a very ſmooth and ſhining ſurface, whence they appear to be of a lighter colour than the adjoining cuticle; they are diffuſed, at a conſiderable diſtance from each other, over the loins, ſhoulders, and upper part of the arms. This eruption affects infants about a year old, and moſt commonly ſucceeds ſome of the acute diſeaſes to which they are liable, ſuch as catarrhal fever, or inflammations of the bowels or lungs: the papulæ continue hard and elevated for about a week, and then gradually ſubſide and diſappear. See Willan on Cutan. Diſeaſes, Order 1. Genus 1.

The ſtrophulus *volaticus* being ſometimes connected with a diſorder of the ſtomach and bowels, it becomes requiſite to adminiſter a gentle emetic or ſome laxative medicines; after which the decoction of Peruvian bark will be found of advantage. No external application ſeems neceſſary. The ſtrophulus *confertus*, when the child is otherwiſe healthy, is generally aſcribed to a ſtate of indigeſtion, or ſome feveriſh complaint in the mother or nurſe: but the eruption is frequently ſeen when no ſuch cauſe for it is evident. It may with more probability be conſidered as one of the numerous ſymptoms of irritation, ariſing from the inflamed and painful ſtate of the gums in dentition; ſince it always occurs during that proceſs, and diſappears ſoon after the firſt teeth have cut through the gums. On this view the eruption requires no ſpecific conſideration in medical practice; it can only be alleviated by the general treatment proper for the ſtate of teething, to be mentioned preſently.

This ſpecies of *ſtrophulus* appears under other modifications, which have been miſtaken for meaſles. One very obſtinate and painful form of it is noticed by Dr. Willan, which takes place, though not often, on the lower extremities. The papulæ ſpread from the calves of the legs to the thighs, *nates*, loins, and round the body as high as the navel: being very numerous and cloſe together, they produce a continuous redneſs over all the parts above-mentioned. The cuticle preſently becomes ſhrivelled, cracks in various places, and finally ſeparates from the ſkin in large pieces. During this proceſs a new cuticle is formed, notwithſtanding which the complaint recurs in a ſhort time, and goes through the ſame courſe as before. In this manner, ſucceſſive eruptions take place during the courſe of three or four months; and perhaps do not ceaſe till the child is one year old, or ſomewhat more. Children neceſſarily ſuffer great uneaſineſs from the heat and irritation occaſioned by ſo extenſive an eruption; yet, while they are affected with it, they often remain free from any internal or febrile complaint.

This appearance, Dr. Willan remarks, ſhould be diſtinguiſhed from the *intertrigo* of infants, which exhibits an uniform red, ſmooth, ſhining ſurface, without papulæ; and which affects only the lower part of the *nates* and inſide of the thighs, being produced by the ſtimulus of the urine, &c., with which the child's clothes are almoſt conſtantly wetted. Under the head of *intertrigo*, however, we muſt include all thoſe varieties of *chafing* and *excoriation* which occur in thoſe parts where the ſkin is folded, or in contact, and therefore liable to conſiderable attrition. (See INTERTRIGO.) From the delicate ſtructure of the ſkin of infants, Dr. Hamilton obſerves, *excoriations* readily take place wherever one part of it is in conſtant contact with another, unleſs the moſt careful attention be paid to keep every part dry. The ears, neck, arm-pits, and groins are chiefly liable to be affected in this manner. When the excoriations are not allowed to continue for a conſiderable length of time, they ſeldom require any other treatment than being duſted, morning and evening, with prepared tutty, or calamine, or with common aſhes finely powdered, or a little hair-powder or ſtarch. But when a diſcharge of matter is the conſequence of neglected excoriations, a cure can only be obtained by much care and attention; for it is often very difficult to ſtop theſe runnings. Some practitioners have objected to ſuch attempts, on the falſe ſuppoſition that the diſcharge is a ſalutary outlet for an overload of the ſyſtem. Theſe opinions, admirably well calculated to favour the careleſsneſs of nurſes, are founded upon improper views of the operations of nature.

Many different remedies will be found beneficial in different caſes of excoriation; ſuch as waſhing the parts daily with brandy and water, lime-water, a weak ſolution of ſugar of lead, or of white vitriol, and dreſſing them with any mild ointment, as ſpermaceti ointment, Turner's cerate, or ointments containing the oxyd of zinc, or a ſmall portion of the ointment of nitrate of mercury. While theſe means are purſued, an open ſtate of the bowels is to be promoted, by the occaſional exhibition of any gentle laxative, as manna diſſolved in water, &c. The uſe of mild mercurials, as alteratives, ſuch as the hydrargyrus cum creta, &c. is likewiſe beneficial.

Some other ſlight eruptions, to which young children are liable, chiefly of the papular form, are mentioned by Dr. Underwood, and require no other treatment than an attention to the ſtate of the bowels, or the uſe of ſome teſtaceous powders. See his Treatiſe on Diſ. of Children, vol. i.

There is a very common eruption, ſays the writer juſt quoted, that calls for more attention, and to which medical writers have given the name of *cruſta lactea*, (or *milk-blotches*, as Dr. Hamilton tranſlates it,) "which has a very unpleaſant appearance, but is, notwithſtanding, equally innocent with the former, and even prevents other complaints. I think I never ſaw an infant," he continues, "much loaded with it, but it has always been healthy, and cut its teeth remarkably well: indeed it falls to the lot of the fineſt children, and ſuch as are well nouriſhed; whence ſome have imagined it owing only to the richneſs of the milk. And it is remarkable in this eruption, that howſoever thick and long-continued the ſcabs may be, the *cruſta lactea* never excoriates, nor leaves any ſcar on the parts." It is not attended with any fever, or obvious derangement of the ſyſtem. The cruſt appears firſt on the forehead, and often extends half way over the face in the form of large looſe ſcabs. It is ſometimes attended with ſevere itching. Practitioners in general affirm that medicines are not required, and are rather injurious than beneficial in this eruption; that mild laxatives, ſo as to keep the paſſage of the bowels free, may be employed, but that all active purgatives are to be avoided; and, laſtly, that where there is exceſſive itching, ſome weak cooling aſtringent lotion, of the acetate of lead, or ſulphate of zinc, ſhould be applied to the parts. Dr. Underwood denies that the *cruſta lactea* ever degenerates into ſcald-head, as ſome authors before him had mentioned. But Dr. Hamilton has pointed out a modification of *cruſta lactea*, which frequently takes place during teething, and is a moſt obſtinate and troubleſome complaint. "This," he ſays, "is characterized by a redneſs of the ſkin round the edge of the incruſtations; by an ichorous or clear-coloured exudation iſſuing from the ſurface of the ſcabs, which concretes, and which tends to carry the diſeaſe over every part of the face which it touches. There cannot be a doubt, indeed, that this form of *cruſta lactea* is contagious, and nothing leſs than a variety of the ſcald-head, or *tinea capitis*, the *Porrigo* of Dr. Willan's nomenclature, in which this ſpecies is called Porrigo *larvalis*. The cure of this modification of the diſeaſe requires conſtant ablution with milk and water, thin gruel, &c., to remove the acrid fluid which exudes, and the application of ſome drying ointment. Some alterative preparation of mercury is likewiſe uſeful internally, ſuch as the hydrargium creta, or the grey oxyd, followed by the vegetable and mineral tonics. See PORRIGO.

Dr. Hamilton has ſtated the following practical concluſions reſpecting the eruptions of children in general. They may all be divided into two claſſes, he obſerves, the *firſt* of which are temporary, or of ſhort duration; are commonly uſhered in with ſymptoms of general indiſpoſition, and are owing to ſome diſorder of the ſtomach or bowels, or to ſome interruption of the uſual excretions or ſecretions: the *ſecond* are of an indefinite duration; break out gradually without any derangement of the ordinary health; and are probably, in moſt inſtances, the effects of ſome diſeaſed condition of the lymphatic ſyſtem, though, ſometimes, they may be occaſioned by a local affection of the ſkin itſelf. The treatment requiſite in theſe two forms of eruption is thus ſtated. In the *firſt* claſs, where ſymptoms of indiſpoſition, ſuch as heat, reſtleſsneſs, ſickneſs, or oppreſſion, are followed by an eruption, a briſk doſe of calomel ſhould be firſt ordered, together with the warm bath, and afterwards occaſional purgatives, and a ſuitable regulation of the diet, are to be adviſed. But, in the *ſecond* claſs, where the appearance of the eruption is unaccompanied by fever or marks of indiſpoſition, ſome of the medicines called alteratives, and the daily uſe of warm bathing, particularly in ſea-water, ſhould be recommended. The medicines to which an alterative power is aſcribed, he continues, are preparations of mercury, of antimony, of ſulphur, and of neutral ſalts; and therefore calomel in very ſmall doſes, or antimonial wine, or the ſulphuret of antimony, or Harrowgate or Cheltenham waters, or ſome imitation of theſe, are the remedies to be chiefly depended upon. It is commonly neceſſary to order a protracted courſe of theſe medicines. In ſome caſes, other topical applications (beſides the warm bath) are neceſſary, to allay irritation, ariſing from exceſſive heat and itching of the ſkin. The moſt efficacious are lime-water mixed with oil, a ſolution of potaſs, and the acetite of ammonia much diluted. The metallic ſolutions are too powerful to be employed, except upon very particular occaſions. Iſſues have been often employed in thoſe caſes, but experience has proved that purging anſwers better. Very diſtreſſing effects have followed the application of a bliſter, where there was a tendency to chronic eruptions of the ſkin. Hamilton's Hints for the Treatment of the principal Diſeaſes of Infancy and Childhood, p. 130.

§ 3. *Dentition*.—It is generally admitted that the time of *teething* is an important period of the infant ſtate, during which a number of diſorders of a formidable character are liable to occur. Dr. Cadogan, indeed, and Dr. Armſtrong ſeem to have entertained a ſomewhat different opinion upon this ſubject, and have aſcribed the complaints, connected with the proceſs of dentition, to ſome other morbid condition of the habit, ſuch as too great fulneſs, or a corrupt ſtate of the fluids: but this appears to be a difference only in terms, and implies an admiſſion of the occurrence of the diſeaſes alluded to. (See Armſtrong on the Diſeaſes moſt incident to Children, &c. p. 61.) It is certain that the natural proceſs of dentition is productive of pain and indiſpoſition in by far the greater number of inſtances: ſome infants, indeed, ſuffer leſs than others, but few enjoy perfect health while teething. We ſhall firſt deſcribe the progreſs of the developement of the teeth, and afterwards the ordinary affections which it excites in the conſtitution.

The *period of teething* is ſubject to conſiderable variety in different inſtances; but in the greater number of caſes, the firſt pair of milk-teeth appear between the fifth and tenth month, and the laſt before the end of the ſecond year. In ſome infants, however, the firſt pair or two are cut by the end of the third month; while, on the other hand, not a few attain the ſixteenth or eighteenth month before a ſingle pair appears. In general, thoſe of the lower jaw are cut before the correſponding ones of the upper jaw; but ſometimes the ſeveral pairs of the upper jaw are cut before thoſe of the lower. The following is the order of ſucceſſion in moſt inſtances: *viz.* firſt, the two middle fore-teeth of the lower jaw; then the correſponding pair in the upper: next follow the two adjoining teeth of the upper jaw; and, after theſe, the two next fore-teeth of the lower jaw: then come the two foremoſt grinders of the upper jaw, and after them the two anterior grinders of the lower jaw: the two eye-teeth make their appearance next; and ſome time after, the two oppoſite to them in the lower jaw: and finally, the poſterior grinders. Of the firſt ſet of teeth there are twenty in all, but in ſome caſes only ſixteen: an interval of one, two, or more weeks is interpoſed between each ſucceſſive pair; and there is commonly a longer interval between the firſt two pair than between the ſucceeding ones. Some children, however, cut their teeth croſs, as it is called, or irregularly, the teeth appearing firſt in the upper jaw, and alſo at a diſtance, inſtead of being contiguous to each other: in ſome rare caſes the grinders come out before the cutting teeth. This is accounted, and with ſome reaſon, an indication of difficult or painful dentition.

At birth the teeth are placed underneath the gums, and each tooth is incloſed in a fine membrane or capſule, which is ſuppoſed to be extremely ſenſible. This capſule, as well as the gum, muſt give way before the tooth can be protruded;

and this is accompliſhed merely by the preſſure of the enlarging tooth, which occaſions the abſorption of thoſe parts. In favourable caſes, the preſſure of the teeth on the gums occaſions pain, and an increaſed flow of the fluids furniſhed by the mouth. Hence the infant is fretful, reſtleſs during the night, drivels continually, and frequently thruſts his little hands, or whatever he can get hold of, into his mouth, to rub his gums; and he has occaſionally ſickneſs, gripes, and looſeneſs. At laſt the corner of a tooth is perceived; but the uneaſineſs ſtill continues for ſome days, when a ſecond one is cut. During the interval between the cutting of the lower and upper teeth, he recovers his ſtrength and uſual good health; but is ſoon again ſubjected to the ſame uneaſineſs.

Were theſe the only complaints which attend teething, little danger might be apprehended; but ſometimes many very formidable ſymptoms occur. In robuſt healthy conſtitutions, a violent fever frequently precedes the appearance of every tooth; the gums are ſwelled and inflamed, the eyes much affected, the belly bound, the ſkin hot; and there is every now and then continued ſcreaming, with inability to ſuck, and the ſleep is ſhort and diſturbed. Weakly infants, where teething is painful and difficult, are oppreſſed with ſickneſs, loath all kinds of food, loſe their colour, fret perpetually, have a conſtant looſeneſs, and become much emaciated. Some, beſides theſe ſymptoms, are ſubject to convulſions, which recur from time to time, till the tooth or teeth are above the gum. In others, cough, various eruptions on the ſkin, ulcerations in the gums, extending ſometimes over the palate, obſtinate inflammation of the eyes, affections of the urinary organs, and ſometimes moſt alarming determination to the head, are occaſionally the effects of teething. All the ſymptoms are much aggravated, if ſeveral teeth be cut at once, or in immediate ſucceſſion.

It is of great importance to be able to aſcertain when any of the diſtreſſing ſymptoms, thus enumerated, ariſe from dentition. This is to be done by a careful examination of the ſtate of the gums. Previous to the protruſion of any tooth, the ſeam, which may be diſtinctly obſerved on the edge of each gum, like a doubling of the ſkin, is done away, and the upper ſurface of the gum is rendered flat and broad, or is elevated in the form of a ſmall ſwelling. The gum of the upper jaw is more apt to appear on the ſtretch than that of the lower. It is not eaſy to diſtinguiſh when the infant ſuffers pain from any part of the gum being preſſed upon; otherwiſe that might aſſiſt in pointing out the advance of ſome particular tooth or teeth, becauſe ſuch a degree of fretfulneſs attends teething, that every attempt to feel the ſtate of the mouth never fails to irritate the child.

An eſtimate of the danger attending dentition is to be formed chiefly from the nature of the ſymptoms. Experience proves that puny delicate infants often ſuffer leſs than the moſt healthy and robuſt. In this climate it has been found that ſummer is a more favourable ſeaſon for teething than winter. Some infants cut their fore-teeth without any pain or difficulty, but are much diſtreſſed while cutting the grinders or eye-teeth; although, when the protruſion of the firſt two pair of fore-teeth is accompanied or preceded by great uneaſineſs, there is reaſon to fear that the individual will ſuffer during the whole period of teething: yet the converſe of the propoſition does not hold good; that is, where little derangement of health attends the firſt pair or two, it is not to be concluded that all the other teeth are to advance with the ſame facility. It is well known, that during teething every acute diſeaſe is more than uſually dangerous; and it is alſo a well eſtabliſhed fact, that infants, in a crowded city, are more liable to pain and alarming ſymptoms at that time of life than thoſe reared in the country.

The treatment of the ordinary complaints attending teething, ſhould conſiſt in moderating the pain, in regulating the ſtate of the bowels, and in the continued employment of every means calculated to promote the general health of the infant. With theſe views, ſmall quantities of anodyne balſam may be rubbed on the back-bone at bed-time, when the infant ſeems to be greatly pained. He ought to be fed with beef-tea twice a-day, if weakly, and if his bowels be looſe; and ſhould be kept as much as poſſible in the open air when the weather is favourable; the cold bath ought not to be laid aſide in theſe caſes, unleſs other concurrent diſorders ſhould render it neceſſary, as nothing is more conducive to promote general ſtrength. Looſeneſs, if exceſſive, muſt be moderated; and if the belly be bound ſhould be artificially induced by gentle laxative medicines. When reſtleſs during the night, the child ſhould be taken out of bed, and carried about in a cool airy room; and if not relieved in a ſhort time, he ought to be put into a warm bath. Finally, he ſhould be allowed ſomething to rub his gums with, which will both gratify his wiſhes, and tend to promote the abſorption of the parts incloſing the tooth. A piece of wax-candle, or of recent liquorice-root, is preferable to coral; though the latter ſubſtance is in no other reſpect injurious than that it may be, by awkwardneſs, forced into the noſtril or eye.

The management, when alarming ſymptoms take place, muſt be varied according to circumſtances; but in every caſe the indications to be fulfilled are, to cut aſunder the parts which reſiſt the protruſion of the tooth or teeth, and to palliate diſtreſſing or troubleſome complaints. Some of theſe, which occur alſo under other circumſtances, will be noticed immediately. See alſo DENTITION. Hamilton's Hints, &c. p. 73, *et ſeq.*

Canker of the mouth, cancrum oris, as it has been called, is moſt commonly connected with dentition; it is ſometimes troubleſome to remove, but commonly a trivial complaint. It ſometimes makes its appearance in the firſt month, Dr. Underwood ſays; at others, about the time of teething; and frequently at the age of ſix or ſeven years, when children are ſhedding their firſt teeth, and the ſecond are making their way through the gums. It conſiſts of little foul ſores covering the gums, and extending ſometimes to the inſide of the lips and cheeks. It is ſaid to occur during teething moſt frequently where the gums have not been lanced. It is generally eaſily cured by keeping the body open, and by the uſe of ſome mild aſtringent application to the mouth. As much white vitriol, or rock alum, as will give a moderate roughneſs to a little honey, is uſually ſufficient for this purpoſe; or if it ſhould not effect a cure when the complaint makes its appearance at the time of teething, it will generally go away as ſoon as the teeth are protruded. The worſt ſpecies of this complaint, witneſſed by Dr. Underwood, has occurred during the ſecond period of dentition, when a child has been ſhedding a number of teeth together, leaving the decayed ſtumps behind, which have been neglected to be drawn out. The whole gums will then ſometimes be ſpongy, or diſſolve into foul ſpreading ulcers; and ſmall apertures will be formed, communicating from one part to another, accompanied with an oozing of a fetid and ſometimes purulent diſcharge. If the ſtumps of the decayed teeth are eaſily acceſſible, they ought to be extracted, and ſome aſtringent applications made to the parts, conſiſting of myrrh, Peruvian bark, alum, or cryſtals of tartar, made into a paſte with honey of roſes, or lotions made with the ſame ingredients, aſtringent tinctures, or mineral acids.

§ 4. *Bowel Complaints.*—Under this head we ſhall include the diſorders of the whole of the alimentary canal, and of the organs connected with it, both by function and ſtructure. Theſe conſtitute, perhaps, the moſt important tribe of the diſeaſes of children; inaſmuch as they not only produce conſiderable diſtreſs by their direct effect in deranging the functions, but are likewiſe indirectly the ſource of numerous, ſevere, and even fatal conſtitutional maladies, both chronic and acute. The diſorders of the ſtomach, indeed, are ſeldom very formidable or troubleſome in early life; but the derangements of the biliary ſecretion, of the inteſtinal canal, and of the meſenteric glands and abſorbents, which are much connected with each other, are productive of much miſchief during the whole period of infancy and childhood.

Sickneſs and Vomiting.—A ſlight degree of ſickneſs is a very common occurrence in infants, as their ſtomach is ſo irritable, that it readily rejects any overload of food. But this ſpontaneous puking is attended with little violence to the ſtomach; the milk, or other aliment, ſeems to come up without any ſenſible action of the part, or any reaching effort of the child: and when the food is brought up immediately after ſucking or feeding, and in an almoſt unchanged ſtate, ſuch ſickneſs is obſerved to be not incompatible with a thriving ſtate. Unleſs when the ſickneſs is extremely violent, therefore, or long continued, it is ſeldom neceſſary to interfere. But when means are required to moderate or to allay it, we muſt endeavour to aſcertain the cauſe of the vomiting, and apply them accordingly. The cauſes of ſickneſs at the ſtomach in infants are either ſome altered condition of the nurſe's milk, or the preſence of ſome indigeſtible ſubſtance in the ſtomach. If the nurſe have been under the influence of any violent emotion of the mind, or if ſhe have begun to be out of order, or even to have the feelings preceding that event, it may be concluded that there is ſome morbid change in the milk. During the progreſs of teething, the increaſed quantity of ſaliva, together with its acrimony, proves occaſionally the cauſe of ſickneſs. In ſuch caſes the ſtomach may require the diſcharge of its contents by means of a gentle emetic: a little warm water or chamomile tea, or, at the moſt, ſome preparation of ipecacuan, will anſwer this purpoſe. Antimonials, in doſes which excite vomiting, are frequently injurious to infants, and ſometimes actually ſink, with great rapidity, the living powers. When the vomiting is kept up by irritability of the ſtomach, which is ſometimes the conſequence of its actions having been diſturbed by a cauſe already removed, ſlight cordials and aromatics may be given to ſtrengthen the organ and abate its ſenſibility, and if theſe fail, ſome ſtimulant or anodyne may be applied externally.

It muſt be obſerved, however, that habitual vomiting from over-diſtention of the ſtomach, to which many infants are liable, may lay the foundation for future weakneſs of the digeſtive organs, and ſhould therefore be guarded againſt by every precaution. For this reaſon, infants ought not to be allowed to ſuck too much at a time, and large quantities of ſpoon-meat ſhould never be given in the early months.

Diarrhœa or *Looſeneſs.*—The natural appearance of the ſtools of infants ſhould be familiar to every practitioner. In general the colour is that of a bright orange, the conſiſtence is pulpy and curdled, and the ſmell is not offenſive. Any deviation in theſe reſpects marks ſome diſeaſed ſtate of the ſtomach or bowels. During infancy, from two to four evacuations, within the twenty-four hours, ſeem neceſſary and uſeful; and even where that number is exceeded, it is not to be regarded as injurious, unleſs the health be impaired, or the fleſh be rendered flabby. The appearance of the ſtools, in caſes of diarrhœa, is very various. When they are green, and at the ſame time emit a ſour ſmell, which ariſes from the prevalence of acidity in the firſt paſſages, there is generally griping and fretfulneſs, but the complaint is not dangerous. It generally yields to a laxative, or, in very young infants, to a medicine compoſed of a little magneſia and rhubarb, with a little diſtilled water of dill or penny-royal, with a few drops of ammoniacal ſpirit, or of the compound tincture of camphor. The nurſe's food ſhould be regulated in this caſe, and the infant ought to have no other food, in addition to the milk, than arrow-root.

Slimy ſtools are generally the effect of expoſure to cold, though they occaſionally ariſe from ſome irritation or accumulation in the bowels. In both caſes they are apt to be ſlightly ſtreaked with blood. If there be violent pain, or ſymptoms of fever, introſuſception is to be dreaded. A doſe of cold-drawn caſtor oil, together with the warm-bath, or fomentation of the belly with flannels wrung out of hot water, are commonly all that are neceſſary, if the diſeaſe be attended to at the beginning. Where ſlimy ſtools are of the colour of clay, and emit a putrid ſmell, the infant ſoon becomes emaciated, and the diſeaſe often terminates fatally, though its progreſs be ſlow. Alteratives, with opiate frictions and occaſional purgatives, afford the chief means of relief. If the infant be ſtill at the breaſt, the milk ſhould be changed, a practice which ought to be adopted in every inſtance where there is great tendency to looſeneſs.

The moſt diſtreſſing caſes of diarrhœa are thoſe in which the ſtools are liquid, brown, black, or clay-coloured, and of an offenſive ſmell. As the diſorder proceeds, very unfavourable ſymptoms occur, ſuch as emaciation and dryneſs of the ſkin, ſwelling or ſhrinking of the belly, with an altered appearance of the countenance; and there is a conſtant fretting or peeviſhneſs of temper. Swellings of the glands of the groin, and a little uneaſineſs of breathing, as if there were a ſlight tendency to cough, are alſo very unfavourable ſymptoms. In many of theſe caſes the purging is the effect of a diſeaſed ſtate of ſome of the digeſtive organs, or of the meſenteric glands; but in others it ariſes from an irregular action of the former organs. In theſe diſorders ſome practitioners begin the treatment by the uſe of emetics; but the advantages of theſe medicines are not very obvious, while the diſadvantages reſulting from their debilitating and irritating qualities in the ſtomach are ſometimes unequivocal. On the whole, the continued uſe of alterative medicines, which maintained a ſteady but gentle action upon the alimentary canal and the adjoining viſcera, ſeems to be the moſt ſucceſsful treatment in theſe complaints; the phyſician, at the ſame time, correcting and modifying their operation according to circumſtances, and palliating urgent ſymptoms. Part of the diet, in theſe caſes, ſhould conſiſt of weak beef tea or chicken broth, with rice, or boiled cow's milk with baked flour, or arrow-root. The occaſional uſe of injections of thin ſtarch and laudanum, in the proportion of eight or ten drops of the latter to two table-ſpoonfuls of the former, may be employed to moderate the diſcharge when the ſtrength is much reduced.

Of the ſevere and often fatal ſpecies of diarrhœa, juſt alluded to, there is one form which is known in Scotland by the name of the "*weaning braſh*," and which has been well deſcribed by Dr. Cheyne. (Eſſays on the Diſeaſes of Children. Eſſ. ii.) It occurs after weaning a child too ſuddenly, eſpecially at an unfavourable ſeaſon, as the autumn. It commences, ſometimes two or three days after weaning, but frequently not for three or four weeks, with a purging and griping, and green ſtools. This, being erroneouſly aſcribed to teething, is perhaps neglected, and the ſymptoms increaſe, a retching and vomiting ſupervene, and are gradually followed by a loathing of every kind of food, emaciation and ſoftneſs of the fleſh, reſtleſſneſs, thirſt, and fever of a hectic character. But the moſt characteriſtic ſymptom of this diſeaſe is a conſtant peeviſhneſs, the effect of unceaſing griping pain, expreſſed by the whine of the child, but eſpecially by the ſettled diſcontent of its features. In the progreſs of the diſeaſe, the evacuations from the belly ſhew very different actions of the inteſtines, and great changes in the biliary ſecretion; for they are ſometimes of a natural colour, at other times ſlimy and aſh-coloured, and ſometimes lienteric. The diſeaſe ſeldom proves fatal before the ſixth or ſeventh week; but ſometimes an earlier termination is ſuddenly produced by inceſſant vomiting and purging, or by convulſions, from the extreme irritation in the bowels.

By diſſection Dr. Cheyne aſcertained the ſtate of the viſcera in children who had died of this diſeaſe. In every caſe the inteſtinal canal, from the ſtomach downward, abounded with ſingular contractions, and had in its courſe one or more intus-ſuſceptions; the liver was exceedingly firm, larger than natural, and of a bright red colour; and the gall-bladder, which was enlarged, contained a dark-green bile. In ſome diſſections the meſenteric glands were found ſwelled and inflamed; in others, however, they were ſcarcely enlarged, and had no appearance of inflammation. It is probable, therefore, that this diſeaſe is owing to an increaſed ſecretion of acrid bile, or rather to the morbid ſtate of the liver which occaſions this; and that the extremely irritable ſtate of the whole abdominal viſcera, marked by the ſpaſmodic contractions and intus-ſuſceptions, &c. is occaſioned by the preſence and paſſage of this acrid excretion.

As the exciting cauſe of this *weaning braſh* is apparently too ſudden an alteration of the diet of a child at an unfit ſeaſon, it follows that children ought at all times, but more particularly in the autumn, to be weaned gradually, and well accuſtomed to the food on which they are afterwards to ſubſiſt before they are finally taken from the breaſt. At the beginning of the diſeaſe, or even later, when the attack is ſlight, Dr. Cheyne recommends a doſe or two of rhubarb, to the extent of five or ſix grains, at the interval of two days between each doſe; and that, in the mean time, the child ſhould take half or a third part of a grain of ipecacuan powder, mixed with ſix or eight grains of prepared chalk, and a ſmall portion of ſome aromatic powder, as caſſia, every four or five hours. A ſtarch glyſter, with five or ſix drops of laudanum in it, may be adminiſtered at bed time with advantage, if there be much griping along with the purging. The ſucceſs of theſe remedies, however, will depend upon a ſtrict attention to diet. An animal diet produces leſs irritation than one which is ſolely compoſed of vegetable matter. Eggs, the finer kind of light ſhip-biſcuit, or arrow-root, cuſtard, the juice of lean meat, plain animal jellies, broths freed from their oily part, and milk, are proper articles of nouriſhment. The breaſt milk might perhaps be reſtored with advantage. Vegetables of all ſorts, particularly fruits, acids, and compoſitions of which ſugar or butter form a part, and fermented liquors of every kind ſhould be ſtrictly prohibited. The feet ſhould be kept warm by woollen ſtockings, and flannel worn next the ſkin; and the warm bath and fomentations may be frequently uſed to alleviate the continual ſpaſms. Dr. Cheyne, however, taught by ſubſequent experience, recommends ſmall doſes of calomel as the moſt effectual remedy againſt the weaning braſh, and other chronic forms of bilious diarrhœa. He generally gave half a grain of calomel, morning and evening, or a grain every night, for a week or ten days. After the third or fourth doſe there is generally a great change, he ſays, in the colour of the alvine diſcharge; it becomes of a dark mahogany colour, and is in general more offenſive. When this change takes place it produces a favourable change in the diſorder. Soon afterwards, the children become free from fever, more placid, and in a day or two more their appetite returns, with their former complexion, and every other demonſtration of health. He never found, he adds, in the many caſes in which he has given calomel, that it produced ſalivation, or any other unpleaſant effect. Cheyne, Eſſay ii. On the Bowel Complaints more immediately connected with the Biliary Secretion.

Coſtiveneſs.—This oppoſite condition of the bowels, though ſeldom occurring in young infants, is productive, in children a little more advanced, of many diſtreſſing complaints. Some infants, indeed, ſeem to be habitually coſtive; and there is certainly a conſiderable variety, in reſpect to the ſtate of the bowels, in different individuals. But what may be properly termed coſtiveneſs is never to be regarded as a natural deviation peculiar to any infant: it is always the effect of diſeaſe, or of the nurſe's milk, or of the food. If one copious evacuation take place every twenty-four hours, and the infant be thriving, there is no occaſion for interference; but if there be any greater torpor of the bowels than this, ſuitable remedies are to be employed. It is generally proper to treat the caſe at firſt as if it were the conſequence of diſeaſe; and on this account a briſk laxative may be given every day, for four or five times ſucceſſively. The beſt laxatives for infants are manna, calcined magneſia, calomel, and cold drawn caſtor-oil; and Dr. Hamilton recommends a laxative ſyrup, prepared with treacle and a ſtrong infuſion of ſenna.

Where theſe means fail, there is reaſon to attribute the coſtiveneſs to the nurſe's milk. Sometimes that peculiar ſtate of the milk may be altered by regulating the diet, and opening freely the bowels of the nurſe. While proper means are tried for this purpoſe, the infant's bowels are to be kept clear by ſome mild laxative. But if it be found that the milk ſtill poſſeſſes that injurious quality, the nurſe ſhould, if poſſible, be changed. Where this cannot be done, four or five drops of antimonial wine may be given to the infant every night at bed-time, and inſtead of the ordinary food, panada, made with ſmall beer and treacle, ſhould be ſubſtituted.

Temporary coſtiveneſs may be at any time removed by a ſuppoſitory, made of a ſmall piece of yellow ſoap, ſhaped like a very large Dutch writing-quill. This may be rendered more powerful, if neceſſary, by being dipped, previous to uſe, into ſome powdered ſea-ſalt. Suppoſitories are more efficacious in infants, and much more eaſily managed than glyſters, though theſe latter means are alſo ſometimes uſeful. In caſes of obſtinate conſtipation, attended with ſymptoms of great oppreſſion, aloës, ſuſpended in treacle or ſyrup, is more powerful than any other laxative; from four to eight grains may be thus given for a doſe. Many practitioners err, Dr. Hamilton affirms, by directing too ſmall doſes of laxative medicines for infants.

At a more advanced period of childhood, a morbid ſtate of the alimentary canal, of which *coſtiveneſs* is a conſpicuous ſymptom, frequently occurs, and is the ſource of ſeveral varieties of diſeaſe, both chronic and acute, which conſtitute perhaps the moſt frequent maladies of the puerile age. The firſt of theſe, to which we ſhall direct the attention of the reader, has been called, by Dr. Hamilton, ſenior, phyſician to the Royal Infirmary at Edinburgh, maraſmus, See his Obſervations on Purgative Medicines, chap. iii. edit. 2d.

Maraſmus includes a variety of ſymptoms which affect children of both ſexes. The diſeaſe ſteals on gradually, and the following are the early ſymptoms by which it is characterized: a ſluggiſhneſs, and laſſitude on ſlight exertion, depravity and loſs of appetite, a flabbineſs and waſting of the muſcular fleſh, fulneſs of the features, and paleneſs or paſty colour of the countenance, ſwelling of the upper lip, a conſtant itching of the noſe, fœtid breath, with a ſwelling of the belly, an irregular and generally coſtive ſtate of the bowels, and a change in the colour and odour of the fæces. When theſe ſymptoms have continued for ſome time other more urgent complaints enſue. There is an alternate paleneſs and fluſhing of the countenance, followed by heat and dryneſs of the ſkin, feeble and quick pulſe, thirſt, great fretfulneſs, increaſing debility, and diſturbed ſleep, during which the little patients grind or gnaſh their teeth, and are ſubject to involuntary ſtarting, and twitching of the different muſcles, and, when awake, to a conſtant picking of the noſtrils or lips, or even of the eyes, and to involuntary geſticulations, approaching to convulſions.

Every caſe of *maraſmus* does not neceſſarily include all theſe ſymptoms; for they occur in different combinations. The diſeaſe appears moſt commonly among weak and infirm children, whether they are ſo from delicacy of conſtitution, or from incidental cauſes. It is particularly prevalent in large and populous cities, where children are deprived of ready acceſs to exerciſe in pure air, and ſicken and pine in the nurſery; or when they are confined in crowded and airleſs ſchool-rooms, whither they are ſent, partly for the purpoſes of education, and partly, to uſe a common phraſe, with the view of being kept out of harm's way. Children alſo, who are employed in manufactories, where their occupation and confinement are ſuch as to weaken and enervate them, are liable to be attacked with this diſeaſe. Irregularity in diet and improper food alſo give riſe to maraſmus. It is accordingly obſerved to prevail moſt in the ſummer and autumn, the ſeaſons which afford an opportunity of eating unripe fruit and vegetable articles from the garden.

Maraſmus has generally been attributed to the preſence of worms in the alimentary canal. But the *aſcarides*, which are often paſſed in great numbers by children, are not accompanied, except incidentally, by the ſymptoms of maraſmus; and the *tænia*, or tape-worm, is altogether unknown in infancy and childhood. The *lumbricus*, or round worm, muſt therefore be the generally ſuppoſed cauſe of the ſymptoms of maraſmus. But the diſeaſe occurs, in numerous inſtances, and is cured, when no worms are ſeen; and, on the other hand, the preſence of *lumbrici* in the bowels is by no means an uniform cauſe of bad health, and has been frequently noticed when maraſmus did not occur. Various anthelmintic medicines, however, have been ſucceſſively in vogue for the cure of the diſeaſe, upon the ſuppoſition of the exiſtence of worms; but the utility of ſuch of them as have been found to be moſt beneficial, Dr. Hamilton believes to have been in proportion to the purgative powers which they poſſeſſed. He ſays, "when I conſider the languor and laſſitude which precede this maraſmus; when I recollect the conſtitutional or acquired debility of thoſe who are more particularly expoſed to be affected by it; inſtead of adopting the common opinion of its being occaſioned by worms, I am more diſpoſed to think, that a torpid ſtate, or weakened action of the alimentary canal, is the immediate cauſe of the diſeaſe; whence proceed coſtiveneſs, diſtention of the bowels, and a peculiar irritation, the conſequence of remora of the fæces. I have accordingly been long in the habit of employing purgative medicines for the cure of this maraſmus; the object is to remove indurated and fœtid fæces, the accumulation perhaps of months; and as this object is accompliſhing, the gradual return of appetite and vigour mark the progreſs of recovery." Obſ. on Purg. Med. p. 51.

Since the practical concluſions are the ſame, it is not of material importance by what theoretical views they are ſupported; but we accord with the following obſervations of Dr. Hamilton, junior, (profeſſor of midwifery at Edinburgh, whoſe excellent "Hints for the Treatment of the principal Diſeaſes of Infants, &c." we have before quoted.) "There can be little doubt," he ſays, "that neither the mere accumulation of the ſtools, nor the torpor of the bowels, on which that appears to depend, can explain the various ſymptoms produced by this condition of the digeſtive organs. There is every reaſon to ſuppoſe that there is an altered action, not only in the ſtomach and inteſtines, but alſo in the liver and lacteals, perhaps in all the parts concerned in the digeſtion of the food. When this has continued for a certain time, the accumulation of acrid matter, which is the conſequence, adds greatly to the irritation, and while all this is going on, the circulating juices become depraved." Hints, &c. p. 113.

In the treatment of maraſmus, then, the leading objects are, to remove the accumulating maſs of morbid and irritating fæces from the bowels, to alter the morbid actions of the digeſtive organs, and to palliate the diſtreſſing ſymptoms which occur. The two firſt, which are the curative indications, are both fulfilled by a ſteady and perſevering adminiſtration of purgative medicines.

In the incipient ſtage, while the diſeaſe is mild, the bowels are not altogether torpid and inactive, neither are they overloaded with accumulated fæces. Mild purgatives, therefore, repeated at proper intervals, effect a cure. They preſerve the bowels in proper action, carry off fæces which had begun to be offenſive and hurtful, and prevent farther accumulation. The diſeaſe yields in a few days to this treatment, and all that is farther required is ſome tonic medicine, which ſhall ſtrengthen the ſtomach and bowels, together with a due regulation of diet, and occaſionally a purgative at bed-time, the patient being likewiſe much in the open air. Preparations of iron are found the beſt tonics in theſe caſes; and children readily take the wine of iron, or the filings covered with ſugar. In ſelecting the purgatives, it is neceſſary to flatter the taſte of our young patients. Powder of jalap is not altogether unpleaſant: the mild neutral ſalts, diſſolved in a ſuitable quantity of beef-tea, are alſo convenient purgatives: but calomel will prove, on ſeveral accounts, the moſt certain and uſeful remedy of this kind.

When the confirmed ſtage of maraſmus has been allowed to arrive, manifeſt danger threatens the young ſufferer, whoſe remaining fleſh and ſtrength are rapidly waſted by the ſupervening fever; while proſtration and depravity of appetite withhold neceſſary nouriſhment, and at the ſame time the more inactive ſtate of the bowels, and greater bulk of feculent matter, throw additional difficulties in the way of a cure. Under theſe circumſtances, an active practice ſhould be adopted, with the view of ſtimulating the inteſtines, and of putting the collected maſs in motion without delay. Theſe ends are beſt obtained by giving ſmall doſes of the purgative medicine, and by repeating theſe frequently, ſo that the latter doſes may ſupport the effects of the preceding ones. When the bowels are once opened, ſtronger purgatives, given at longer intervals, will accompliſh the cure.

While the purgative medicines are thus exhibited, it is monly makes ; and for the ſame reaſon, Hoffman gave it the appellation of *Febris lenta infantum*.

The fever in queſtion is moſt commonly preceded for ſome days, and occaſionally for weeks, by ſymptoms of indiſpoſition, much reſembling the early ſymptoms of *maraſmus*. The child is obſerved not to look well, and his colour often changes. He is indolent, ſpiritleſs, and fretful ; frequently picks his noſe, lips, and fingers, even ſometimes till he draws blood : his breath is offenſive, and he is affected with a ſhort dry cough. If he can ſpeak, he complains of pain in his head, or belly, or both : and when ſtill older, he ſays alſo that he is faint and weak. He has a deſire for drink more than for food ; is much troubled with wind ; and his belly is ſometimes larger than natural. In his ſleep, he ſtarts, moans, and makes a grating noiſe with his teeth. His urine puts on a milky appearance almoſt as ſoon as made, and, in a few minutes, depoſits a ſediment of the ſame colour, leaving the body of the urine with very little colour. His bowels are generally in the extreme, being either coſtive or looſe.

After theſe ſymptoms have continued for a longer or ſhorter time, the fever makes its appearance, ſometimes preceded by a diſtinct cold fit, at other times, however, ſo gradual in its approach, that the commencement is not obſerved. It always aſſumes more or leſs of the remittent form, when it is diſtinctly ſeen, and the exacerbations are long, and the remiſſions ſhort, in proportion to the violence of the fever. During the exacerbation all the ſymptoms are increaſed ; there is great heat of ſkin, and the patient is drowſy, and ſleeps, but not ſoundly ; for he ſtarts, moans, talks incoherently, and even ſcreams in his ſleeps. The wind is particularly troubleſome, makes a rumbling noiſe in the bowels, and is exploded copiouſly both upwards and downwards, with manifeſt relief. The cough is more frequent, and the breathing is quickened and oppreſſed. The patient is often ſick, and ſometimes retches, and even vomits phlegmy ſtuff of various colours. The pulſe beats from a hundred and forty to a hundred and ſixty pulſations in the minute. In the remiſſions, all the ſymptoms abate. The patient is wakeful, is attentive to things around him, often inclines to be playful, and is in general averſe to lying in bed. What ſleep he has is uſually compoſed. The pulſe beats from a hundred and twenty to a hundred and thirty ſtrokes in a minute.

Theſe exacerbations and remiſſions often occur with a conſiderable degree of regularity; the exacerbation generally beginning in the evening, and the remiſſion taking place in the morning: but in the more acute form of the diſeaſe, there are one or two ſhorter exacerbations during the day. In the latter caſe, both in the exacerbations and remiſſions the ſkin is commonly dry : when ſweats happen, they are partial, affecting only the head, breaſt, or palms. The belly and palms are always warmer than any other part of the body. Where there is only the nocturnal exacerbation, it is uſually terminated by a profuſe ſweat ; and through the day, the ſkin is temperate, but feels dry and harſh. The patient has no appetite, and ſcarcely any thirſt ; ſo that in many caſes, it is with great difficulty that he can be made to take either food or drink. The ſtate of the bowels is uncertain ; but the ſtools are always unnatural, either as to their colour, conſiſtence, contents, or ſmell : moſt commonly they are morbid in all theſe reſpects ; for they are either whiter or darker than natural ; they are always more offenſive ; are ſeldom without a great deal of ſlime, and ſometimes conſiſt of nothing but ſlime : ſometimes they froth and ferment like yeaſt.

The patients frequently paſs worms in the courſe of this fever, even when they were never known to void any before. Theſe worms are not only thrown off by vomiting and ſtool, but are ſometimes obſerved to work themſelves out of the body both ways, ſeemingly unaſſiſted by any exertions on the part of the patient's organs. But in many caſes of this fever, no worms are ever ſeen.

When the fever is on the decline, the exacerbations grow milder and ſhorter, and at length diſappear one after another ; the appetite returns by degrees ; the ſleep becomes calm and refreſhing, attended with a general moiſture of the ſkin, and the ſtools approach more and more to the natural ſtate, till they become as in health. The duration of this fever, in its more acute form, is from eight or ten days to a fortnight or three weeks ; in the more ſlow and mild form, it will laſt for two or three months or more.

That the cauſe of this remittent fever of children lies in the alimentary canal, and is of the ſame nature with that from which maraſmus, and ſeveral other infantile diſeaſes originate, has not been doubted ſince it was ſo well pointed out by Dr. Butter. It is proved, in the firſt place, by the ſimilarity of the ſymptoms with which it is preceded and uſhered in, and, ſecondly, by the nature of the alvine diſcharges during its continuance, but more eſpecially by the ſucceſs of the practice, which is founded upon this principle, and conſiſts in carrying off the accumulation of morbid excretions from the bowels, and augmenting their ſtrength. The ſame cauſe operating in different conſtitutions, will produce a different ſeries of ſymptoms ; and it is probably from the peculiar irritability of habit in ſome children, that this fever is produced, by the ſame morbid ſecretion and accumulation in the *primæ viæ*, which give riſe to maraſmus, and other chronic maladies in others. " It may be accelerated by cold, fatigue, or the like ;" ſays Dr. Butter, (ſpeaking of the remittent fever,) " but the principal cauſes are crude accumulations in the firſt paſſages, which, with a very irritable prediſpoſition, draw the inteſtinal canal into ſpaſm, &c." whence the irritation is communicated to the reſt of the body, and general fever induced.

Cure of the infantile remittent fever.—The two principal indications of cure are, to allay the febrile irritation, and to remove the great irritating cauſe ; the former of which, although in a great meaſure palliative only, is an object of conſiderable importance. It is extremely deſirable, therefore, that from the firſt occurrence of the febrile ſymptoms, the child ſhould be kept ſtill, and quiet, in a chamber which is of a cool temperature ; that all ſolid food and ſtimulating drink ſhould be cautiouſly abſtained from ; and the ſole ſupport of the patient be diluting and nouriſhing liquors, ſuch as ſmall broth, gruel, and barley-water.

The ſecond, or proper curative indication, is fulfilled by ſuch medicines as keep up a conſtant gentle action upon the bowels, and contribute at once to diſlodge the morbid accumulation, and to correct the morbid condition, of the alvine excretions. This purpoſe may be effected either by the neutral ſalts, or by ſmall doſes of mercurial laxatives, eſpecially in combination with abſorbents. Dr. Butter gives the preference to the former ; and commonly employs the *polychreſt ſalt*, which promotes both urine and ſtools. For a child of five years old (and proportionally for a younger or older ſubject) he diſſolves a drachm of this ſalt in a quarter of a pint of water, ſweetening it with two drachms of ſugar. Of this mixture two ſpoonfuls are adminiſtered every four hours, or at ſuch intervals, when the child is awake, that the whole may be finiſhed in twenty-four hours. This medicine is to be repeated daily, ſo as to promote one, two, three, or four ſtools, according to the circumſtances of the caſe, the larger number in the more acute forms of the diſeaſe. When the fever is attended with a looſeneſs, Dr. Butter interdicts the uſe of the neutral ſalts, and preſcribes the extract of hemlock (*Conium*, Linn.); the quantity of five grains to be taken in the courſe of 24 hours, ſuſpended in water with a little ſugar. It relieves every ſymptom of the fever, he ſays, and at the ſame time gradually carries off the looſeneſs. Under ſimilar circumſtances, we have ſeen eſſential ſervice from ſmall doſes of ſome mercurial, combined with abſorbents, as the *Hydrargyrus cum Creta*, of the London Pharmacopœia; or a grain of calomel united, by rubbing, with a little ſoda and teſtaceous powder. While the *conium* is given as above-mentioned, as much rhubarb may be adminiſtered as will keep the body gently open, where the fever is not very acute.

When there is great reſtleſſneſs and vociferation, the belly ſhould be fomented with flannel cloths, wrung out of a decoction of chamomile, and applied agreeably warm, for twenty minutes or half an hour at a time, as occaſion may require; and this operation ſhould be repeated as often as the ſymptoms return. As the diſeaſe declines, the child may be allowed to return gradually to his uſual diet and way of life; but ſome care will be requiſite, that he may not have his free liberty as to eating, drinking, and exerciſe, until he has recovered his full fleſh and ſtrength; and the medicines above recommended muſt be continued till the fever is quite gone.

Catarrhal fever is not a very frequent diſeaſe during infancy, and when it does occur, ſeldom requires any other treatment, than an emetic at the beginning, an open ſtate of the bowels, and the warm bath every night while it continues. When it extends to the degree of pulmonary inflammation, bliſtering the cheſt is often an effectual remedy, or, in ſtrong children, the application of leeches to the cheſt may be reſorted to. The principle of treatment, indeed, is the ſame in theſe complaints, whether they occur in the early or later periods of life; except that the infantile conſtitution is more eaſily acted upon by remedies, and therefore that a laxative and a bliſter will often accompliſh a degree of alleviation of fever, which more active meaſures will be required to produce in adults. See CATARRH and PERIPNEUMONY.

Among the fevers incident to children, the *acute hydrocephalus*, or water in the head, ſhould be deſcribed; but we have already given the hiſtory of that important diſeaſe in its place. (See HYDROCEPHALUS.) It remains for us to ſay a few words on the ſubject of convulſions.

§ 6. *Convulſive Diſeaſes.*—The ſubject of convulſions, in general, has been treated under its proper head, (ſee CONVULSIONS,) as well as the moſt ſevere modifications of convulſive diſeaſe, the epilepſy and St. Vitus's dance. (See EPILEPSY and CHOREA.) It will, therefore, be ſufficient to ſtate here ſome circumſtances relative to the convulſions of infants in particular. And firſt it muſt be obſerved, that, in conſequence of the peculiar ſuſceptibility of impreſſion in the nervous ſyſtem of infants, many circumſtances excite convulſions at that early age, which have no ſuch effect at a ſubſequent period of life. Accordingly it is well known, that in general the younger the infant is, the more readily do fits occur, and that ſome families are more liable than others to the diſeaſe, apparently from a weak ſtate of the nervous or vaſcular ſyſtem being communicated from the parents. The obvious exciting cauſes are dentition, mechanical injuries, acute diſeaſes, impurities of the air, paſſions of the mind, indigeſtible or poiſonous ſubſtances in the ſtomach or bowels, over-diſtention of thoſe organs, irritations in them from acrid matter or worms, the ſtate of the ſyſtem previous to the appearance of ſmall-pox, meaſles, &c. All theſe act by diſturbing the nervous ſyſtem, and altering or deranging the actions of the veſſels.

In ſome caſes convulſions come on ſuddenly; the infant, from being in the moſt perfect health, turns in a moment livid, his eyes and features are contorted, and his limbs and whole frame are thrown into violent agitations. Theſe ſymptoms are ſucceeded by a ſuſpenſion of the vital powers, as in faintings, which may or may not prove fatal. Sometimes the attack is gradual, and the firſt ſymptoms are not eaſily diſcerned by the attendants: the infant ſhews ſome degree of uneaſineſs; he changes colour, his lips quiver, his eyes are turned upwards, and he unexpectedly, as it were, ſtretches himſelf out, or his hands become clenched. The leſſer degrees of theſe are called by the nurſes *inward fits*. Convulſions commonly precede the fatal termination of moſt of the diſeaſes of infancy, which explains the reaſon of their appearing in the bills of mortality to be of ſuch frequent occurrence. Accordingly, where they take place after any conſiderable indiſpoſition, they are to be regarded as the harbingers of death. But even where the infant had been in perfect health previous to the attack, the event is always to be conſidered as extremely uncertain, for a ſingle fit may kill. In ordinary caſes, the danger is to be eſtimated by the degree of violence of the fit, and by the cauſe which had produced it. Thus if the cauſe be ſome irritation, which is naturally of temporary duration, or which can be eaſily removed, a favourable event may be looked for; but if it be not obvious, it may be ſuſpected to be ſome ſtate of the brain, which admits of no remedy. In many inſtances, where it was impoſſible to diſcover the cauſe of the fits during life, an accumulation of water within the ventricles of the brain has been found after death.

There is no medicine poſſeſſed of any ſpecific power in ſuppreſſing convulſions, although cochineal, miſletoe, muſk, and other ſubſtances, have been at different times extolled for ſuppoſed virtues of this nature. One of the moſt effectual means of alleviating the fits, is to immerſe the child, during their attack, in a tubful of water, heated to 96° of Fahrenheit's thermometer, or to a warmth that the hand can eaſily bear. In very young infants opiates are not always ſafe, and cannot be truſted in the hands of nurſes or inexperienced perſons; but in children upwards of eighteen months, where the warm bath does not ſpeedily ſucceed in abating the convulſions, from one or two to four or five drops of the tincture of opium might be adminiſtered, according to the ſeverity of the fits: or a proportionate quantity of the camphorated tincture of opium, or of the extract of poppies diffuſed in a little water. Profeſſor Hamilton has recommended a ſubſtitute for opium, which may be given to younger children; namely, the tincture of *hyoſcyamus*: "twenty drops, evening and morning, have been repeatedly given to infants within ſix months of age." He remarks, that, when the convulſions have been the effect of hooping-cough, great benefit has been derived from this medicine. Camphor, in the form of glyſter, has ſeemed ſerviceable in ſome few caſes, the ſame author ſtates, but chiefly in children beyond the ſecond year. He adds, "when a child ſeems to be ſuddenly deprived of life by one or two fits, if he appeared previouſly in good health, he ought on no account to be conſidered as irrecoverably loſt; but the common means for reſtoring ſuſpended animation ſhould be carefully employed, as long as his colour is not entirely changed." Hints, &c.

Some other diſeaſes, which occur in infancy and childhood, might here have been deſcribed; eſpecially the glandular affections, both internal and external; the various diſorders of the ſcalp, as the ſcald-head, ring-worm of the ſcalp, &c.; the rickets, and ſo forth. But ſome of theſe are not peculiar to the age of childhood, and others are ſufficiently important to be diſcuſſed more at length. See TABES *meſenterica*, or meſenteric conſumption; SCROFULA, PORRIGO, RICKETS.

The *prevention of diſeaſes* in children depends principally on the regulation of the diet and clothing, ſleep, exerciſe in the open air, and cleanlineſs. On the ſubject of the two or three laſt points we have little to ſay, as the value of a proper attention to them is now generally underſtood. In regard to diet, it may be ſufficient to ſtate, that, after weaning, preparations of milk, of eggs, of vegetable and animal jellies, ſhould precede ſolid animal food; that, during childhood, a proper proportion of animal and vegetable matter ſhould be uſed; and that all condiments, except ſalt, are unneceſſary, and all ſpirituous fermented liquors pernicious. In reſpect to clothing, it is important to obſerve, that the attempts to rear children in a hardy manner, by allowing their legs to be bare, and other parts of the body to be much expoſed (a practice ſanctioned by ſome great names) have proved moſt unſucceſsful; for by theſe means not only has the growth been, in many inſtances, ſtinted and perverted, but the conſtitution has been much injured, and, in ſome caſes, life abſolutely deſtroyed, in conſequence of inflammations of the lungs and bowels, or various ſcrofulous affections, thus excited. It would appear, indeed, that ſcrofulous and conſumptive diſeaſes owe their origin principally to the cold and humidity of our climate, and the deleterious influence of theſe cauſes upon the conſtitution in childhood was ſtrikingly illuſtrated in the attempt lately made by the Sierra Leone Company to form an eſtabliſhment for the education of African children in this country. Mr. John Pearſon, who ſuperintended this inſtitution, ſtates that they all died of conſumption: they almoſt uniformly became ſcrofulous; they bore the firſt winter tolerably well, but drooped during the ſecond, and the third generally proved fatal to them; inſomuch that it became neceſſary to abandon the plan. Now we cannot but deem the ſituation of a child, who is to be hardened by thin clothing, as analogous to that of theſe African children, and to believe that, by ſuch deluſive attempts to give ſtrength, the perfect and healthy evolution of the ſyſtem is prevented, and the foundation laid for ſcrofula, conſumption, and other chronic diſeaſes.

INFANTS, *Running Eyes of*. See OPHTHALMY.

INFANTS *at Bethlehem*, *Slaughter of*, *by Herod*, a fact mentioned in the goſpel of St. Matthew, chap. ii. 16.; but diſputed on account of the ſilence of Joſephus, who has written the hiſtory of the Jews, and particularly the reign of Herod. The fact is not in itſelf improbable nor incredible, if we conſider the cruelty of Herod's diſpoſition and other ſavage acts of which he was guilty (ſee HEROD), and more eſpecially if we recollect, that the ſlaughter, mentioned by St. Matthew, was perpetrated upon the occaſion of tidings brought to Jeruſalem, of the birth of one who was "king of the Jews." Joſephus, who has given an account of a terrible execution made in Herod's court, and at Jeruſalem, about the ſame time, upon the occaſion of ſome predictions, that God was about to take away the kingdom from Herod, might omit the murder of the infants at Bethlehem from a fear of being charged with a deſign to load Herod unreaſonably, or a fear of rendering his hiſtory diſagreeable by too particular a detail of cruel actions. The ſilence of Joſephus, it is ſaid, is no more an objection againſt St. Matthew, than the ſilence of other writers with regard to facts mentioned by Joſephus is an objection againſt him. Joſephus, however, if he was a firm Jew, as moſt writers have ſuppoſed, had a particular reaſon for paſſing over this event at Bethlehem, becauſe he could not have mentioned it, without giving great advantage to the Chriſtian cauſe. If he had written that Herod, at the latter end of his reign, had put to death all the young children at Bethlehem, on occaſion of a report ſpread at Jeruſalem, that the "king of the Jews" had been newly born there, he would very much have gratified the Chriſtians; ſince it was well known, when he wrote, that about thirty years after the death of Herod, Jeſus, being then about thirty years of age, had been ſtyled the "king of the Jews," and had been publicly crucified at Jeruſalem with that title; and it was firmly believed by all his followers, that he was the great perſon ſpoken of under that character, and was now advanced to dominion and power. If Joſephus did not wiſh to ſerve the Chriſtians and their cauſe, he would therefore be ſilent with regard to this fact. But it has been alleged, that the Greek and Roman hiſtorians are ſilent with reſpect to this event: but this may eaſily be accounted for, if we conſider, that the Roman empire was at this time ſo extenſive, that the affairs of many dependent princes have been loſt in the crowd. Nevertheleſs, St. Matthew's account is confirmed by the teſtimony of ancient Chriſtian authors. Juſtin Martyr, Irenæus, Origen, and other Chriſtian writers have mentioned the fact. Moreover, there is alſo a noted paſſage in Macrobius, a heathen author, who flouriſhed in the latter end of the fourth century, who, among other jeſts of Auguſtus, has this: "When he (Auguſtus) had heard that among the children within two years of age, which Herod king of the Jews commanded to be ſlain in Syria, his own ſon had been killed, he ſaid, "it is better to be Herod's dog than his ſon." Macrob. Sat. l. ii. c. 4. This paſſage, if we deduce no other inference from it, ſhews, that Herod's ſlaughter of the infants in Judea was a thing well known in Macrobius's time, and was not conteſted by the heathens. See Lardner's Works, vol. i. chap. 2.

INFANTA, in *Geography*, a river of Africa, which runs into the Indian ſea, S. lat. 32°.

INFANTE and INFANTA, are titles of honour given to the children of ſome princes; particularly thoſe of the houſes of Spain and Portugal.

It is uſually ſaid, that the appellation of infanta was introduced into Spain on occaſion of the marriage of Eleanor of England with king Ferdinand of Caſtile: and that their ſon Sancho was the firſt that bore it. But this is contradicted by Pelagius, biſhop of Oviedo, who lived in the year 1100, and who informs us, that the titles infante and infanta were uſed in Spain ever ſince the reign of king Evremond II.

INFANTICIDA, in *Mythology*, the name of a deity to whom, according to Lycophron, children were ſacrificed by the Greeks. It is not likely that this was originally the name of any ſeparate deity; but from the lamentable frequency of this almoſt incredible offering, this horrible diſtinction was appropriately applied to, moſt probably, Hecate, or ſome other form of the goddeſs Diana, of multifarious names and characters. The ſubject of infanticide has lately undergone more than uſual diſcuſſion, and the prevalence of the practice, both heretofore and exiſting, proved of greater extent than could have been imagined. See the following article.

INFANTICIDE, or child murder, is an enormity that our reaſon and feelings would lead us to reckon as a crime of very rare occurrence. That it ſhould exiſt at all is, at the firſt view, ſurpriſing,—that it ſhould prevail to any extent is difficult of belief,—that parents ſhould be its perpetrators is in a high degree painful to imagine; but that mothers ſhould be the executioners of their own offspring, nay, their habitual and ſyſtematic executioners, is ſuch an agonizing contemplation, ſuch an outrage on humanity, as every amiable feeling of our nature ſickens and revolts at. But that this lamentable cuſtom is, notwithſtanding, extenſively prevalent, has lately been developed ſo demonſtratively, that, however comfortable it may be to our wounded ſenſibility to indulge the hope of error, it is, unhappily, the wantonneſs of ſcepticiſm to doubt. To try, however, as it would ſeem, the ſketch of our credulity, we are imperatively called upon to believe this unparalleled enormity of a race, heretofore ſuppoſed to be the moſt humane in exiſtence; *viz.* of the Hindoos: but of that race, which is among the moſt tender in other reſpects, we are conſtrained to believe that by them this ſad deed has been ſyſtematically and univerſally perpetrated!

A few years ago it was diſcovered by Mr. Duncan, then reſident at Benares, that a ſect of Hindoos in that neighbourhood, called Ràj-kùmàr, was in the habit of deſtroying all their female infants. A notice of this extraordinary fact was ſoon after publiſhed in the fourth volume of the Aſiatic Reſearches, by ſir John Shore (now lord Teignmouth), then governor-general of India. Mr. Duncan ſucceeded in perſuading this deluded tribe to relinquiſh their barbarous habit; and ſo effectually, that no inſtance has ſince been diſcovered of an infringement of the written penal obligation that the chiefs and other individuals of that tribe then voluntarily entered into. As well as the Ràj-kùmàrs, other ſects of Hindoos, in the vicinity of Benares, were found to have been in ſimilar habits, though to a leſs extent, and they executed a ſimilar deed of renunciation.

The ſame gentleman, the Hon. Mr. Duncan, now governor of Bombay, in the year 1800, being at Surat, heard incidentally that on the weſtern ſide of India alſo, and eſpecially in the contiguous countries of Guzerat, Kutch, and Sind, infanticide was extenſively practiſed; due enquiry amply confirmed the fact. Availing himſelf of the recently improved connection between the Britiſh government and that of the Gaikawar, or ſovereign of Guzerat, Mr. Duncan, through the able and zealous co-operation and agency of colonel Walker of the Bombay eſtabliſhment, our political reſident and military commander in Guzerat, again ſucceeded in the entire and effectual abolition of the cuſtom; all the chiefs of the tribes in which it had obtained binding themſelves and their families, and adherents, to a permanent renunciation and diſcontinuance of it; rendering themſelves, in default of a due obſervance of the agreement, obnoxious to penal inflictions on the part of the Britiſh and Gaikawar governments.

Among the military tribe of Jàrejàh, infanticide was found moſt common; ſo common, indeed, that a Jàrejàh female was very rarely ſeen or heard of. The men of this tribe procured wives from others who reared their daughters. The number of infants, thus ſacrificed, amounted, by one computation, to 30,000 annually, in the peninſula of Guzerat alone: but this colonel Walker deemed an exaggeration. Another eſtimate, erring probably on the other hand, reckoned 2000 as nearer the annual amount. It appeared to be the univerſal practice to deſtroy the infant immediately on its birth: this was done generally by the midwife, or ſome female attendant; ſometimes, however, by the mother! The father never interfered, and the name or ſubject of a daughter was never mentioned in his preſence. Sometimes the infants were ſmothered in various ways, or ſuffered to expire from want of nurture: different methods of deſtruction are related, and it ſeems to have been a matter of indifference how, provided the inhuman deed were done.

In the contiguous countries of Kutch and Sind, infanticide alſo prevails: but it has not been aſcertained to what extent. It is recognized and avowed by the perſons poſſeſſing the powers of government, who aſſert the antiquity of the uſage, and forbid any interference on our part with a view to its abolition: our endeavours to effect that ſalutary end have in thoſe quarters entirely failed.

It is, however, a conſoling fact to reflect on, that ſolely through Britiſh interpoſition this cuſtom has been put an entire ſtop to throughout the vaſt extent of our influence in India. None of the former governments, whether Hindoo or Mahometan, of the countries comprehended within that term, appear ever to have made any effort toward working ſo deſirable a reform, although the religious tenets of both pointedly prohibit the practice.

Theſe particulars we have gathered from a recent publication by major Moor, on "Hindoo Infanticide;" wherein he has given at length all the correſpondence and negociations that led to its diſcovery and ſuppreſſion in India; with notices of a ſimilar cuſtom, which, and the expoſure of children, he proves to have prevailed both in ancient and modern times among many nations in almoſt every part of the world. He adduces many ſpeculations on its exiſtence, origin, and effects; extending, indeed, to a lengthened diſcuſſion on a ſubject that, as much as any on record, evinces the almoſt incredible inconſiſtency and weakneſs, and wickedneſs of man. See Infanticida.

INFANTOS, in *Geography*, a town of Spain, in New Caſtile; 20 miles W. of Alcaraz.

INFANTRY, the body of foot ſoldiers, in an army, or other corps. See Foot.

The infantry ſtand contradiſtinguiſhed from the *cavalry*, or horſe, which ſee.

Europe is unqueſtionably indebted to the Swiſs for a total change in the military ſyſtem, particularly ſo with regard to foot ſoldiers.

Dr. Robertſon, in the firſt volume of his hiſtory of Charles V. p. 105, obſerves, that the ſyſtem of employing the Swiſs in the Italian wars, was the occaſion of introducing a total innovation in the military cuſtom. The arms and diſcipline of the Swiſs were different from thoſe of other European nations. During their long and violent ſtruggles in defence of their liberties againſt the houſe of Auſtria, whoſe armies, like thoſe of other conſiderable princes, conſiſted chiefly of heavy-armed cavalry, the Swiſs found that their poverty, and the ſmall number of gentlemen reſiding in their country, at that time barren and ill cultivated, put it out of their power to bring into the field any body of horſe capable of facing the enemy. Neceſſity compelled them to place all their confidence in infantry; and in order to render it capable of withſtanding the ſhock of cavalry, they gave the ſoldiers breaſt-plates and helmets, as defenſive armour, together with long ſpears, halberts, and heavy ſwords, as weapons of offence. They formed them into large battalions, ranged in deep and cloſe array, ſo that they could preſent on every ſide a formidable front to the enemy. (See Machiavel's Art of War, b. ii. chap. ii. p. 451.) The men at arms could make no impreſſion on the ſolid ſtrength of ſuch a body. It repulſed the Auſtrians in all their attempts to conquer Swiſſerland. It broke the Burgundian Gendarmerie, which was ſcarcely inferior to that of France, either in number or reputation; and when firſt called to act in Italy, it bore down, by its irreſiſtible force, every enemy that attempted to oppoſe it. Theſe repeated proofs of the deciſive effects of infantry, exhibited on ſuch conſpicuous occaſions, reſtored that ſervice to reputation, and gradually re-eſtabliſhed the opinion which had been long exploded, of its ſuperior importance in the operations of war. But the glory the Swiſs had acquired, having inſpired them with ſuch high ideas of their own prowefs and conſequence, as frequently rendered them mutinous and inſolent, the princes who employed them became weary of depending on the caprice of foreign mercenaries, and began to turn their attention towards the improvement of their national infantry.

The German powers having the command of men, whom nature has endowed with that ſteady courage and perſevering ſtrength which form them to be ſoldiers, ſoon modelled their troops in ſuch a manner, that they vied with the Swiſs both in diſcipline and valour.

The French monarchs, though more ſlowly, and with greater difficulty, accuſtomed the impetuous ſpirit of their people to ſubordination and diſcipline; and were at ſuch pains to render their national infantary reſpectable, that as early as the reign of Louis XII. ſeveral gentlemen of high rank had ſo far abandoned their ancient ideas, as to condeſcend to enter into their ſervice.

The Spaniards, whoſe ſituation made it difficult to employ any other than their national troops in the ſouthern parts of Italy, which was the chief ſcene of their operations in that country, not only adopted the Swiſs diſcipline, but improved upon it, by mingling a proper number of ſoldiers, armed with heavy muſkets, in their battalions; and thus formed that famous body of infantry, which, during a century and a half, was the admiration and terror of all Europe. The Italian ſtates gradually diminiſhed the number of their cavalry, and in imitation of their more powerful neighbours, brought the ſtrength of their armies to conſiſt in foot ſoldiers. From this period, the nations of Europe have carried on war with forces more adapted to every ſpecies of ſervice, more capable of acting in every country, and better fitted both for conqueſts, and for preſerving them.

INFANTRY, *Exerciſe*. See EXERCISE.

INFANTRY, *Foreign*. The foreign infantry in the ſervice of Great Britain, according to the returns delivered in on the 1ſt of November 1800, conſiſts of Loyal French Emigrants, Caſtries, Mortemart, Roll and Dillon; Meuron ditto; four ditto Dutch, each having a company of artillery attached, and one Dutch rifle with a company of pioneers; Lowenſtein's corps, which was not completed, and one corps of foreign invalids. Staff to a foreign hoſpital. There are beſides 16 unattached foreign officers who receive full pay, 166 ditto on half pay, 504 aged and wounded ditto, 46 foreign officers widows, 44 children of foreign officers who have died in the king's ſervice. There is alſo a ſmall corps of eſtafettes, which is attached to the waggon train, and conſiſts wholly of foreigners.

INFANTRY, *Heavy armed*, among the ancients, were ſuch as wore a complete ſuit of armour, and engaged with broad ſhields and long ſpears. They were the flower and ſtrength of the Grecian armies, and had the higheſt rank of military honour.

INFANTRY, *Light armed*, amongſt the ancients, were deſigned for ſkirmiſhes, and for fighting at a diſtance. Their weapons were arrows, darts or ſlings.

INFANTRY, *Light*, have only been in uſe ſince the year 1656. They have no camp equipage to carry, and their arms and accoutrements are much lighter than the common infantry, or battalion men. Wherever there is light cavalry, there ſhould be light infantry to act in conjunction.

INFARCTION, in *Medicine*, *infarctus*, ἔμφραξις of the Greeks, is ſynonymous with *obſtruction*, and *congeſtion*, and denotes that ſtate of any organ of the body, which is tumid, with the blood-veſſels loaded, and is more eſpecially applied to the tumours produced by a chronic inflammation of the parts.

INFARCTION *of the Liver*. See HEPATITIS, and LIVER, *Chronic Diſeaſes of*.

INFARCTION *of the Spleen*. See SPLENITIS and SPLEEN.

INFARCTION *of the Meſentery*. See MARASMUS, and TABES *Meſenterica*.

INFATUATE, to prepoſſeſs any one in favour of ſome perſon or thing that does not deſerve it, ſo far as that he cannot eaſily be diſabuſed.

The word *infatuate* comes from the Latin *fatuus*, *fool*, of *fari*, *to ſpeak out*; which is borrowed from the Greek φαω, whence φατης, which ſignifies the ſame with *vates* in Latin, or *prophet* in Engliſh: and the reaſon is, becauſe their prophets or prieſts uſed to be ſeized with a kind of madneſs or folly when they began to make their predictions, or deliver oracles.

The Romans called thoſe perſons infatuated, *infatuati*, who fancied they had ſeen viſions, or imagined the God Faunus, whom they called *Fatuus*, had appeared to them.

INFECTION, in *Medicine*, a word uſed in two acceptations: firſt as denoting the effluvium or infectious matter, exhaled from the perſon of one diſeaſed, and capable of communicating the diſeaſe to others who inhale it; in which ſenſe it is ſynonymous with *contagion*: and ſecondly, as ſignifying the act of communication of ſuch morbid effluvium, by which the diſeaſe is transferred. The word comes from the Latin verb *inficio*, which properly ſignifies to dye of ſome other colour, or to cauſe ſomething to be imbibed. See CONTAGION.

INFEODATION *of Tithes*, in *Law*. See TITHES.

INFERIÆ, in *Antiquity*, ſacrifices offered to the dii manes, or the ſouls of deceaſed heroes and illuſtrious perſons; or even of any relation or perſon whoſe memory was held in veneration.

INFERIOR, ſtands oppoſed to ſuperior.

INFERIOR *Courts of Record*, in *Engliſh Law-writers*, is uſed as a general name for corporation-courts, courts-leet, and ſheriffs-torns. See COURTS.

Moſt courts are ſubordinate to ſome other; but for diſtinction ſake the term inferior-court is by ſir Matthew Hale, and others, applied in the manner here mentioned.

INFERIOR *Maxilla*, *Ocean*, *Planet*. See the ſubſtantives.

INFERIOR *Penis*, in *Anatomy*, a name given by Spigelius to one of the muſcles of the penis, generally called the accelerator by the moderns; and by Veſalius, and others of his time, primus penis.

INFERIOR *Obliquus*, *Serratus*, *Subſcapularis*. See the ſeveral articles.

INFERIORIS *labii depreſſor*, *labii elevator*. See DEPRESSOR, and ELEVATOR.

INFERNAL GLASS, in *Chemiſtry*, is a name given to the bolt-head, when its ſtem is continued downward into the body of the glaſs veſſel, and left open only by a very ſmall orifice.

INFERNAL *Salt*, a name given by Hoffman, and ſome other of the chemical writers, to nitre; they have alſo called it *cerberus chemicus*.

INFERNAL *Stone*. See LAPIS *Infernalis*, CAUSTIC, and CRYSTALS *of Silver*.

INFERNALS, in *Artillery*, floating mines conſtructed in the bodies of ſhips or boats. The firſt inventor of them, or at leaſt the firſt who put them in practice, was Frederick Jambelli, an Italian engineer, at the ſiege of Antwerp by the Spaniards under Alexander, prince of Parma, in the year 1585. A very particular and intereſting relation of their wonderful effects is given by Strada, in his "Hiſtory of the

Belgic War." The great deſtruction made by theſe cauſed ſeveral others to be tried; but none of them ſucceeded. At Dunkirk and St. Maloes they were tried by the Engliſh; at Havre de Grace by the Engliſh and Dutch, under king William; and one was conſtructed by the French to be uſed againſt Algiers, in 1688, but it was not employed. St. Remi, in his Memoirs of Artillery, has given a ſection and view of the infernal uſed at St. Maloes. See a deſcription and figure of it in Groſe's Military Antiquities, v. i. p. 410.

INFERTILITY. See Fertility.

INFIBULATION, in *Antiquity*. It was a cuſtom among the Romans, to infibulate their ſinging boys, in order to preſerve their voices: for this operation, which prevented their retracting the prepuce over the glans, and is the very reverſe to circumciſion, kept them from injuring their voices by premature and prepoſterous venery: ſerving as a kind of padlock, if not to their inclinations, at leaſt to their abilities. It appears by ſome paſſages in Martial, that a leſs decent uſe was made of infibulation among the luxurious Romans: for ſome ladies of diſtinction, it ſeems, took this method of confining their paramours to their own embraces. Juvenal alſo hints at ſome ſuch practice. Celſus, a chaſte author, ſays, infibulation was ſometimes practiſed for the ſake of health; and nothing deſtroys it more than the ſilly practice this operation ſeems intended to prevent. This practice is not perhaps likely to be revived; if, however, any one who has ſuffered in his conſtitution by prepoſterous venery, ſhould be able to get children, and ſhould be inclined to prevent the ſame misfortune in them, by infibulation; the method of doing it is thus:

The ſkin which is above the glans is to be extended, and marked on both ſides with ink, where it is perforated, and then ſuffered to retract itſelf. If the marks recur upon the glans, too much of the ſkin has been taken up, and we muſt make the marks farther; if the glans remain free from them, they ſhew the proper place for affixing a fibula: then paſs a needle and thread through the ſkin where the marks are, and tie the threads together; taking care to move it every day, until the parts about the perforations are cicatriſed: this being effected take out the thread, and put in the fibula; which the tighter it is the better. Celſus, lib. vii. cap. 25.

Authors have not determined what the fibula of the ancient ſurgeons was, though no doubt they were for different purpoſes. In the preſent caſe, the fibula ſeems to mean a ring of metal, not unlike what the country people put through the noſes of ſwine.

INFIDEL, a term applied to ſuch perſons as are not baptized, and that do not believe the truths of the Chriſtian religion. See Deist.

INFIERNO, in *Geography*, one of the ſmaller Canary iſlands, between Lancerotta and St. Clara.

INFIESTO, a town of Spain, in the province of Aſturias; 20 miles E. of Oviedo.

INFILTRATION, in *Geology*, is one of the proceſſes of nature, by which ſtony hardneſs ſeems to have been given or increaſed in mineral ſubſtances or ſtrata, in certain ſituations, effected by the infiltration or ſoakage of water laden with ſtony particles, through porous ſubſtances, and then depoſiting their lapidiferous contents: Mr. Kirwan, in his "Geological Eſſays," pages 45, 128, 131, and 412, has conſidered this mode of indurating the terreſtrial ſtrata, and quoted a number of curious mineral changes and appearances aſcribed to this agent.

INFINITE, that which has neither beginning nor end: in which ſenſe God alone is infinite.

Infinite is alſo uſed to ſignify that which has had a beginning, but will have no end: as angels, and human ſouls.

This makes what the ſchoolmen call *infinitum a parte poſt*; as, on the contrary, by *infinitum a parte ante*, they mean that which has an end, but had no beginning. See Indefinite and Finite.

Infinite, in *Mathematics*, is applied to quantities which are either greater or ſmaller, than any aſſignable ones. In which ſenſe it differs not much from what we otherwiſe call *indefinite* or *indeterminate*. Thus, an

Infinite, or *Infinitely great line*, in *Geometry*, denotes only an indefinite or indeterminate line; to which no certain bounds or limits are preſcribed.

Infinite *Quantities*. Though the idea of magnitude infinitely great, or ſuch as exceeds any aſſignable quantity, does include a negation of limits; yet all ſuch magnitudes are not equal among themſelves; but beſides infinite length and infinite area, there are no leſs than three ſeveral ſorts of infinite ſolidity; all of which are quantities *ſui generis*; and thoſe of each ſpecies are in given proportions.

Infinite length, or a line infinitely long, is to be conſidered, either as beginning at a point, and ſo infinitely extended one way; or elſe both ways from the ſame point: in which caſe the one, which is a beginning of infinity, is one-half of the whole, which is the ſum of the beginning and ceaſing infinity, or infinity *a parte ante*, and *a parte poſt*, which is analogous to eternity in time or duration; in which there is always as much to follow, as is paſt any point or moment of time.

Nor does the addition or ſubtraction of time, length or ſpace of time, alter the caſe, either as to infinity or eternity; ſince neither the one nor the other can be any part of the whole.

As to infinite ſurface or area, any right line infinitely extended both ways on any infinite plane, divides that plane into equal parts, the one to the right, and the other to the left of the ſaid line; but if from any point in ſuch a plane, two right lines be infinitely extended, ſo as to make an angle; the infinite area, intercepted between theſe infinite right lines, is to the whole infinite plane, as the arc of a circle drawn on the point of concourſe of thoſe lines as a centre, intercepted between the ſaid lines, is to the circumference of the circle; or as the degrees of the angle to the 360 degrees of a circle.

For an example—Two infinite right lines meeting at a right angle on an infinite plane, do include a quarter part of the whole infinite area of ſuch a plane: if two parallel infinite lines be ſuppoſed drawn on ſuch an infinite plane, the area intercepted between them will be likewiſe infinite; but at the ſame time it will be infinitely leſs than the ſpace intercepted between two infinite lines, that are inclined, though with never ſo ſmall an angle, becauſe in the one caſe the given finite diſtance of the parallel lines diminiſhes the infinity in one degree of dimenſion; whereas in a ſector, there is infinity in both dimenſions; and conſequently the quantities are one infinitely greater than the other, and there is no proportion between them.

From the ſame conſideration ariſe three ſeveral ſpecies of infinite ſpace or ſolidity; for a parallelopiped, or a cylinder infinitely long, is greater than any finite magnitude, how great ſoever; all ſuch ſolids ſuppoſed to be formed on a given baſis, are in proportion to one another as thoſe baſes. But if two of thoſe three dimenſions are wanting, as in the ſpace intercepted between two parallel planes infinitely extended, and at a finite diſtance; or with infinite length and breadth, it have a finite thickneſs; all ſuch ſolids ſhall be as the given finite diſtances one to another.

But theſe quantities, though infinitely greater than the other, are yet infinitely leſs than any of thoſe wherein all the three dimenſions are infinite—Such are the ſpaces intercepted between two inclined planes infinitely extended: the ſpace intercepted by the ſurface of a cone, or the ſides of a pyramid, likewiſe infinitely continued, &c. all which, notwithſtanding the proportion of one to another, and to the το παν, or vaſt abyſs of infinite ſpace (wherein is the locus of all things that are, or can be) or to the ſolid of infinite length, breadth, and thickneſs (taken all manner of ways) are eaſily aſſignable—For the ſpace between two planes is to the whole, as the angle of thoſe planes to the 360 degrees of the circle. As for cones and pyramids, they are as the ſpherical ſurface intercepted by them, is to the ſurface of the ſphere; and therefore cones are as the verſed ſines of half their angles to the diameter of the circle; theſe three ſorts of infinite quantity are analogous to a line, ſurface, and ſolid; and like them, cannot be compared or have any proportion one to another.

INFINITES, *Arithmetic of.* See ARITHMETIC.

INFINITES, *Characters in Arithmetic of.* See CHARACTER.

INFINITE *Decimals.* See REPETEND.

INFINITE *Diſtreſs,* in *Law.* See DISTRESS.

INFINITE *Propoſition,* in *Logic.* See PROPOSITION.

INFINITE *Series.* See SERIES.

INFINITELY *ſmall quantity,* called alſo an *infiniteſimal,* is that which is ſo very minute, as to be incomparable to any finite quantity; or it is that which is leſs than any aſſignable quantity.

An infinite quantity cannot be either augmented or leſſened, by adding or taking from it any finite quantity; neither can a finite quantity be either augmented or leſſened, by adding to, or taking from it an infinitely ſmall quantity.

If there be four proportionals, and the firſt be infinitely greater than the ſecond; the third will be infinitely greater than the fourth.

If a finite quantity be divided by an infinitely ſmall one, the quotient will be an infinitely great one; and if a finite quantity be multiplied by an infinitely ſmall one, the product will be an infinitely ſmall one; if by an infinitely great one, the product will be a finite quantity.

If an infinitely ſmall quantity be multiplied into an infinitely great one, the product will be a finite quantity.

In the method of infiniteſimals, or of infinitely ſmall quantities, the element by which any quantity increaſes or decreaſes, is ſuppoſed to be infinitely ſmall, and is generally expreſſed by two or more terms; ſome of which are infinitely leſs than the reſt, which being neglected as of no importance, the remaining terms form what is called the difference of the propoſed quantity. The terms that are neglected in this manner, as infinitely leſs than the other terms of the element, are the very ſame which ariſe in conſequence of the acceleration, or retardation of the generating motion, during the infinitely ſmall time in which the element is generated; ſo that the remaining terms expreſs the element that would have been produced in that time, if the generating motion had continued uniform, as is farther explained under FLUXION.

Therefore thoſe differences are accurately in the ſame ratio to each other as the generating motions or fluxions. And hence, though infiniteſimal parts of the elements are neglected, the concluſions are accurately true, without even an infinitely ſmall error, and agree preciſely with thoſe that are deduced by the methods of fluxions. In order to render the application of this method eaſy, ſome analogous principles are admitted, as that the infinitely ſmall elements of a curve are right lines, or that a circle is a polygon of an infinite number of ſides, which being produced, give the tangents of a curve, and by their inclination to each other meaſure the curvature. This is as if we ſhould ſuppoſe that when the baſe flows uniformly, the ordinate flows with a motion which is uniform for every infinitely ſmall part of time; and increaſes, or decreaſes, by infinitely ſmall differences at the end of every ſuch time.

But however convenient this principle may be, it muſt be applied with caution and art, on various occaſions. It is uſual, therefore, in many caſes, to reſolve the element of the curve into two or more infinitely ſmall right lines; and ſometimes it is neceſſary (if we would avoid error) to reſolve it into an infinite number of ſuch right lines, which are infiniteſimals of the ſecond order. In general it is a *poſtulatum* in this method, that we may deſcend to infiniteſimals of any order whatever, as we find it neceſſary; by which means any error that might ariſe in the application of it may be diſcovered and corrected by a proper uſe of this method itſelf.

It is alſo to be obſerved, that when the value of a quantity that is required in a philoſophical problem becomes, in certain particular caſes, infinitely great or infinitely little, the ſolution would not be always juſt, though ſuch magnitudes were admitted. As when it is required, to find by what centripetal force a curve would be deſcribed about a fixed point that is either in a curve, or is ſo ſituated that a tangent may be drawn from it to the curve. The value of the force is found infinite at the centre of the forces in the former caſe, and at the point of contact in the latter; yet it is obvious, that an infinite force could not inflect the line deſcribed by a body that ſhould proceed from either of theſe points into a curve; becauſe the direction of its motion in either caſe paſſes through the centre of the forces, and no force, how great ſoever, that tends towards the centre, could cauſe it to change that direction. But it is to be obſerved, that the geometrical magnitude by which the force is meaſured, is no more imaginary in this than in other caſes, where it becomes infinite; and philoſophical problems have limitations that enter not always into the general ſolution given by geometry.

But although by proper care errors may be avoided in the method of infiniteſimals, yet it muſt be owned that to ſuch who have been accuſtomed to a more ſtrict and rigid kind of demonſtration in the elementary parts of geometry, it may not ſeem to be conſiſtent with perfect accuracy, that, in determining the firſt differences, any part of the element of the variable quantity ſhould be rejected, merely becauſe it is infinitely leſs than the reſt; and that the ſame part ſhould be afterwards employed for determining the ſecond and higher differences, and reſolving ſome of the moſt important problems. Nor can we ſuppoſe that their ſcruples will be removed, but rather confirmed, when they come to conſider what has been advanced by ſome of the moſt celebrated writers on this method, who have expreſſed their ſentiments concerning infinitely ſmall quantities in the preciſeſt terms; while ſome of them deny their reality, and conſider them only as incomparably leſs than infinite quantities, in the ſame manner as a grain of ſand is incomparably leſs than the whole earth; and others repreſent them in all their orders, as no leſs real than finite quantities. And although it appears, from what has been ſaid in this article, that a ſatisfactory account may be given for the brief way of reaſoning that is uſed in the method of infiniteſimals; while nothing is neglected without accounting for it; and then the harmony between the method of fluxions, and that of infiniteſimals thus appears more perfect.

And however ſafe and convenient this method may be, yet ſome will always ſcruple to admit infinitely little quantities and infinite orders of infiniteſimals, into a ſcience that boaſts of the moſt evident and accurate principles, as well as of the moſt rigid demonſtrations. It is therefore proper, that this extenſive and uſeful doctrine ſhould be eſtabliſhed on unexceptionable principles. See the articles FLUXION and LIMIT. See alſo Mr. Maclaurin's Treat. of Fluxions, in the Introduction, p. 39, 40, &c. and book i. art. 495 to 502.

INFINITELY *Infinite Fractions*, or all the powers of all the fractions whoſe numerator is one, are together equal to an unit. See the demonſtration hereof given by Dr. Wood, in Hook, Phil. Coll. N° 3. p. 45, ſeq.

Hence, it is deduced, 1°. That there are not only infinite progreſſions, or progreſſions *in infinitum;* but alſo infinitely farther than one kind of infinity. 2°. That the infinitely infinite progreſſions are notwithſtanding computable, and to be brought into one ſum; and that not one finite, but ſo ſmall as to be leſs than any aſſignable number. 3°. That of infinite quantities, ſome are equal, others unequal. 4°. That one infinite quantity may be equal to two, three, or more other quantities, whether infinite or finite.

INFINITIVE, in *Grammar*, the name of one of the moods, which ſerve for the conjugating of verbs.

The infinitive does not denote any preciſe time, nor does it determinate the number, or perſons, but expreſſes things in a looſe indefinite manner; as, *to teach*, &c.

Hence the Latin and modern grammarians have called verbs under this mode, from this their indefinite nature, infinitives. Sanctius has given them the name of imperſonals; and the Greeks that of ἀπαρεμφατα from the ſame reaſon of their not diſcovering either perſon or number.

Infinitives, ſays Mr. Harris, not only lay aſide the character of attributives, but they alſo aſſume that of ſubſtantives, and are diſtinguiſhed with their ſeveral attributes: *e. g.* "Dulce & decorum eſt pro patria *mori*; *ſcire* tuum nihil eſt, &c."

Hence the infinitive has been ſometimes called ονομα ῥηματικον, a verbal noun; ſometimes ονομα ῥηματος, the verb's noun. The reaſon of the appellation is evident in Greek, by its taking the prepoſitive articles before it in all caſes; thus το γραφειν, τȣ γραφειν, τω γραφειν. The ſame conſtruction is not unknown in Engliſh. Thus Spencer,

> "For not to have been dipped in Lethe's lake
> Could ſave the ſon of Thetis *from to die*:" i. e.

ἀπο τȣ θανειν.

The ſtoics held the infinitive as the genuine ῥημα, or verb, a name which they denied to all other modes; becauſe the true verbal character was conceived to be contained ſimple and unmixed in the infinitive only: thus, *to walk*, means ſimply that energy, and nothing more; the other modes, beſides expreſſing this energy, ſuperadd certain affections which reſpect perſons and circumſtances. The infinitive, ſays Priſcian, "ſignificat ipſam rem, quam continet verbum." The infinitive, in the application of it, naturally coaleſces with all thoſe verbs, that denote any tendency, deſire, or volition of the ſoul, but not readily with others. See Harris's Hermes, p. 163, &c.

In moſt languages, both ancient and modern, the infinitive is diſtinguiſhed by a termination peculiar to it; as τυπτειν in the Greek, *ſcribere* in the Latin, *ecrire* in the French, *ſcrivere* in the Italian, &c. but the Engliſh is defective in this point; ſo that to denote the infinitive, we are obliged to have recourſe to the article *to*: excepting ſometimes when two or more infinitives follow each other.

The practice of uſing a number of infinitives ſucceſſively, is a great but a common fault in language; as *he offered to go to teach to write* Engliſh.—Indeed, where the infinitives have no dependence on each other, they may be uſed elegantly enough; as *to mourn, to ſigh, to ſink, to ſwoon, to die.*

INFINITO, in the *Italian Muſic*, is uſed for ſuch canons or fugues, as may be begun again and again: whence they are alſo called *perpetual fugues.* See FUGUE.

INFINITY, the quality which denominates a thing infinite. The idea ſignified by the name infinity is beſt examined by conſidering to what things infinity is by the mind attributed, and how the idea itſelf is framed: finite and infinite are looked upon as the modes of quantity, and are attributed primarily to things that have parts, and are capable of increaſe or diminution, by the addition or ſubtraction of any the leaſt part. Such are the ideas of ſpace, duration, and number. When we apply this idea to the Supreme Being, we do it primarily in reſpect of his duration and ubiquity: and more figuratively, when to his wiſdom, power, goodneſs, and other atttibutes, which are properly inexhauſtible and incomprehenſible: for when we call them infinite, we have no other idea of this infinity but what carries with it ſome reflection on the number, or the extent of the acts or objects of God's power and wiſdom, which can never be ſuppoſed ſo great, or ſo many, that theſe attributes will not always ſurmount and exceed, though we multiply them in our thoughts with the infinity of endleſs number. We do not pretend to ſay, how theſe attributes are in God, who is infinitely beyond the reach of our narrow capacities: but this is our way of conceiving them, and theſe are our ideas of their infinity.

We come by the idea of infinity thus: every one that has any idea of any ſtated length or ſpace, as a foot, yard, &c. finds that he can repeat that idea, and join it to another, to a third, and ſo on, without ever coming to an end of his additions. From this power of enlarging his idea of ſpace, he takes the idea of infinite ſpace, or immenſity. By the ſame power of repeating the idea of any length or duration we have in our minds, with all the endleſs addition of number, we alſo come by the idea of eternity.

If our idea of infinity be got by repeating without end our own ideas, it may be aſked, why do we not attribute it to other ideas, as well as thoſe of ſpace and duration; ſince they may be as eaſily, and as often repeated in our minds, as the other? yet nobody ever thinks of infinite ſweetneſs, or whiteneſs, though he can repeat the idea of ſweet or white, as frequently as thoſe of yard or day? To this it is anſwered, that thoſe ideas which have parts, and are capable of increaſe by the addition of any parts, afford us by their repetition an idea of infinity; becauſe with the endleſs repetition there is connected an enlargement, of which there is no end: but it is not ſo in other ideas; for if to the moſt perfect idea I have of white, I add another of equal whiteneſs, it enlarges not my idea at all. Thoſe ideas, which conſiſt not of parts, cannot be augmented to what proportion men pleaſe, or be ſtretched beyond what they have received by their ſenſes; but ſpace, duration, and number, being capable of increaſe by repetition, leave in the mind an idea of an endleſs room for more; and ſo thoſe ideas alone lead the mind towards the thought of infinity.

We are carefully to diſtinguiſh between the idea of the infinity of ſpace, and the idea of the ſpace infinite. The firſt is nothing but a ſuppoſed endleſs progreſſion of the mind over any repeated idea of ſpace; but to have actually in the mind the idea of ſpace infinite,—is to ſuppoſe the mind already paſſed over all thoſe repeated ideas of ſpace, which an endleſs repetition can never totally repreſent to it; which carries in it a plain contradiction. See SPACE.

This will be plainer, if we conſider infinity in numbers: the infinity of numbers, to the end of whoſe addition every one perceives there is no approach, eaſily appears to any one that reflects on it: but how clear ſoever this idea of the infinity of numbers be, there is nothing yet more evident than the abſurdity of the idea of an actual infinite number. Locke's Eſſay, vol. i. chap. xvii.

INFINITY *of Actions*, in *Law*; the lord of the ſoil may have a ſpecial action againſt him who ſhall dig ſoil in the king's highway: but one ſubject may not have his action againſt another for common nuiſances; for if he might, then every man might have it, and ſo the actions would be infinite, &c. 1 Co. Inſt. 56. 9 Rep. 113.

INFIRMARY, a place where the ſick and weak belonging to any ſociety, or community, are diſpoſed, either for nurſing or cure. See HOSPITAL.

INFLAMMABILITY, is that property of bodies which diſpoſes them to kindle, or catch fire. See FLAME, HEAT, and PHLOGISTON.

INFLAMMABILITY *of Oils*. See OIL.

INFLAMMABLE AIR. See HYDROGEN.

INFLAMMABLE *Springs*. About the middle of the laſt century, a ſpring or well at Broſely in Shropſhire, was much noticed on account of the inflammable exhalations or gaſſes which it emitted, ſo that when a cover was adapted to it, that contracted the ſtream of air, and a candle was applied, it continued to burn with a lambent blue flame for a long time: but the coal-works in the neighbourhood have long ſince drained this well. During the driving of Stoke ſough, to drain the lead mines near Eyam in Derbyſhire, ſuch a quantity of liquid bitumen or rock oil was liberated from the ſmall cavities in the limeſtone, and from geodes of limeſtone in the ſhale above it, that it frequently ſwam on the water in the ſough, in ſufficient quantities to take fire and burn for a time, after the application of a lighted candle: this was called by Mr. Bray, in his "Tour" (p. 176.) a burning ſpring, but improperly, ſeeing that the bitumen was only ſet free by the tools of the workmen, and was not ſpontaneouſly diſcharged from the rock, a condition which ſeems eſſential to a ſpring of any kind. See an account of this ſough, in Mr. Farey's Report on Derbyſhire, vol. i. p. 330.

INFLAMMATION is concerned, either as a cauſe, ſymptom, conſequence, or complication of the greater number of diſeaſes, to which the human body is liable, and hence it has always been conſidered by the moſt enlightened pathologiſts as a ſubject which, in point of importance, is inferior to none in the whole circle of medical ſcience. It intereſts the phyſician, the ſurgeon, the accoucheur, and, in ſhort, every individual, who is in the habit of being entruſted with the treatment of any kind of diſorder, or accidental injury. A knowledge of the nature and laws of inflammation, and juſt ideas reſpecting the means of checking and curing this affection, may be ſaid to conſtitute a key, or introduction, to the comprehenſion of diſeaſes in general; for ſome may be alleged to conſiſt of it, and very few are entirely unattended with it in one ſtage or another. It is for ſuch reaſons, that ſyſtematic authors moſtly treat of it at the very beginning of their works.

The term inflammation, which is derived from the Latin word *inflammatio*, probably owes its origin to an ancient opinion, that there was fire in the part affected, and, if we advert to the conſiderable ſenſation of heat, which the patient experiences in the ſeat of the complaint, the uſe of ſuch an expreſſion ſeems almoſt natural. The Greeks appear to have employed terms of ſimilar import, as φλεγμονη, or φλογωσίς, from φλεγω, *I burn.*

Inflammation is diviſible into ſeveral ſpecies. The diſtinctions chiefly inſiſted upon by ſurgical writers, are the *acute* and *chronic*. When inflammation is unattended with any particular diſeaſe, it is ſometimes called *ſimple* or *healthy*, of which there can only be one kind. But the *morbid* inflammations, or ſuch as are influenced by the preſence of a diſeaſed action, are as numerous and various as diſeaſes themſelves, each diſeaſe, in fact, having its own ſpecific kind of inflammation; as, for inſtance, the ſmall-pox puſtule, the cow-pox veſicle, the carbuncle, eryſipelas, ſcrofula, the venereal diſeaſe, &c.

When common inflammation is ſpoken of, the acute healthy ſpecies is uſually implied, or that which is ſo well known by the name of *phlegmon*. It is attended with four remarkable ſymptoms in the part affected, namely, pain, redneſs, ſwelling and heat: "notæ vero inflammationis ſunt quatuor; rubor et tumor, cum calore et dolore." Celſus, lib. iii. cap. 10.

The pain which accompanies the various ſorts of inflammation, differs very materially both in its degree and kind. In many inſtances, indeed, it might be more proper to ſay, that there is an alteration in the natural ſenſations and ſenſibility of the part, than that there is pain, which latter term leads one to underſtand a degree of agony. Numerous chronic inflammations produce very trivial uneaſineſs in the part, the patient feeling, perhaps in the ſeat of the diſeaſe, merely a ſenſation of weight and heavineſs. It is likewiſe remarked by Richerand, that the pruritus, which precedes and attends certain cutaneous eruptions, ſo far from being painful, occaſions rather an agreeable ſenſation. It is only when the ſenſibility is carried beyond a particular pitch that it amounts to pain. In phlegmonous inflammation the pain is of a throbbing deſcription, and the ſuffering is joined with an annoying ſenſe of weight. In eryſipelas the pain is of a burning kind. In anthrax it is accompanied by a feeling of ſtiffneſs. The ſeverity of the pain is generally in proportion to the vehemence of the inflammation, the ſenſibility of the parts, and the reſiſtance which their ſtructure makes to the tumefaction.

It is a curious fact, of which the practice of ſurgery affords many proofs, that parts which, in their natural healthy ſtate, are not remarkable for their great ſenſibility, are frequently affected when inflamed with an exquiſite degree of tenderneſs and pain. The gums, in the ſound ſtate, are not very ſenſible; they may be divided with a lancet, without any great deal of pain being occaſioned: and the preſſure of hard ſubſtances againſt them in maſtication is not productive of injury. When inflamed, however, in conſequence of decayed teeth, a cold, or any other cauſe, they are affected with extreme ſenſibility, ſwell in a conſiderable degree, and cannot be touched, or preſſed, in the ſlighteſt manner, without much ſuffering being excited. The ligaments are naturally almoſt devoid of ſenſation; but, in ſeveral diſeaſes of the joints, they are even much more painful, than ſome other inflamed parts, which, when ſound, poſſeſs a vaſt deal of ſenſibility.

A preceding remark, therefore, that the pain is in proportion to the natural ſenſibility of the parts affected, is not to be received without exceptions. With reſpect to the immediate way, in which pain is excited in caſes of inflammation, it ſeems moſt rational to impute the degree of ſuffering to the augmented ſenſibility of the nerves, and the unnatural condition in which they are placed. In chronic inflammation, the changes which the parts undergo are ſlow, and the nerves ſeem to have time to adapt themſelves to the alteration;

tion; but in acute inflammation, the mutations are quick, and the pain is, for the moſt part, conſiderable.

The ſwelling appears to be occaſioned by ſeveral circumſtances, yet principally by the increaſed determination of blood to the veſſels of the part, and by an effuſion of coagulating lymph in the interſtices of the cellular ſubſtance. The dilatation of the blood-veſſels, and the interruption of abſorption, probably have alſo a ſhare in producing the effect.

The conſiderable injection of the ſmall veſſels with red blood, and their great increaſe of diameter, afford ſome explanation of the manner in which the preternatural redneſs ariſes. It has been a prevailing ſentiment, that the redneſs of common inflammation is partly owing, not merely to a dilatation, but at the ſame time to an actual increaſe in the number of the blood-veſſels of the inflamed part. New veſſels are ſuppoſed to be generated. This doctrine, however, is far from reſting upon unqueſtionable evidence. When coagulating lymph is extravaſated upon the ſurface of a wound, an inflamed membrane, &c. it is beyond a doubt often rendered vaſcular, or, in other words, becomes furniſhed with new veſſels. But, in the extravaſated lymph of a phlegmonous tumour, we have no evidence to prove that there is any generation of new veſſels. If the veſſels have the appearance of being more numerous, it is becauſe their diameters are enlarged, and many, which previouſly contained only a colourleſs fluid, are now filled with viſibly red blood. Were the extravaſated lymph of a phlegmonous ſwelling to be rendered organized and vaſcular, the tumefaction and redneſs would probably be more permanent, and not admit (at leaſt ſo eaſily as they often do) of reſolution. When adheſions form between two inflamed ſurfaces, the organized ſubſtance, forming the connection, lives after the ſubſidence of the inflammation, and is a permanent effect. (Dict. of Pract. Surgery.) According to Mr. Burns, the ſuppoſition eaſily admits of refutation; for heat, and many other cauſes of inflammation, operate ſo quickly, that there can be no time for the formation of any new veſſels; and yet the redneſs is as great, and the inflammation as perfect, in a minute, as in an hour, or a day, after the application of the exciting cauſe. (Diſſert. on Inflammation). Now that we are noticing the redneſs of inflamed parts, it may be as well to mention the circumſtance of red blood itſelf being ſometimes extravaſated, in conſequence of inflammation. The occurrence generally indicates, that the inflammatory miſchief has been rapid and violent. The moſt ſtriking inſtances, which juſt now preſent themſelves to our mind, are, firſt, that ſtate of an inflamed eye, termed *chemoſis*, for an account of which we refer to OPHTHALMY; and, ſecondly, the ſpots, produced by effuſed blood, on the inner coat of the ſtomach, when this viſcus has been inflamed, in conſequence of poiſon. There is ſtill another circumſtance, which has been mentioned by the celebrated Mr. John Hunter, as conducive to the red appearance of inflamed parts, *viz.* the blood, after it has become venous, retaining a certain degree of the bright ſcarlet colour, which it poſſeſſed in the arteries. We cannot offer any opinion concerning the truth of the latter ſuggeſtion; as coming from Mr. Hunter, it cannot fail to deſerve attention.

The experiments which Mr. Hunter made with the thermometer, tend to evince, that the real augmentation of the heat of an inflamed part is inconſiderable, although it ſeems to be very great, when a judgment is derived from the patient's feelings. If we recollect, that the ſenſibility of the nerves is augmented, we can no longer be ſurprized, that they ſhould convey to the ſenſorium falſe impreſſions. With regard to the manner, in which the increaſed temperature of inflamed parts is produced, this ſubject is explicable on the principles, which apply to the production of animal heat in general. We ſhall merely obſerve, that there is always a greater determination of blood to a part which is in a ſtate of inflammation, than to the ſame part when it is not inflamed. The blood flows through it with augmented velocity, and we always find, that the heat of the whole body, as well as of any portion of it, is always in a ratio to the accelerated ſtate of the circulation. When a perſon runs, he hurries the current of the entire maſs of blood, and his whole body is thrown into a heated ſtate. In fevers, the circulation is quickened, and there is likewiſe general heat. But in inflammation unattended with febrile diſorder, the blood flows only through the inflamed part with increaſed impetuoſity, and, of courſe, the augmentation of heat is local and circumſcribed.

Phlegmon, or what may be called common inflammation, has been regarded by many writers as an affection of the cellular membrane. Its frequent occurrence in every ſituation, both internal and external, has been accounted for by the way, in which the cellular ſubſtance pervades the texture of almoſt every part of the body. Phlegmon is repreſented as being attended with more ſwelling than any other ſpecies of inflammation. The bright red colour in the centre of the tumour gradually extends towards the circumference, and is inſenſibly loſt on the ſurrounding ſkin. The ſwelling, on the other hand, is diſtinctly circumſcribed. The heat has been compared with that ariſing from the ſteam of boiling water. The throbbing, to which we have already adverted, manifeſtly depends upon the pulſation of the arteries, and is ſynchronous with the pulſe of the whole ſyſtem. The throbbing particularly affects the patient himſelf, and the ſurgeon may plainly perceive it when he touches the part, all the ſmall veſſels of which are dilated, and beat in a preternatural degree. In a common whitlow, this vehement throbbing is not confined to the finger, but extends to the large arteries, a conſiderable way up the arm.

The active mind of the late Mr. John Hunter led him to pay much attention to the intereſting ſubject before us, and from him we have many fertile and original obſervations. The principles and laws of inflammation were better explained by this philoſophical obſerver, than by any of his profeſſional predeceſſors. He has noticed the well eſtabliſhed circumſtance, attending phlegmonous and other inflammations, whereſoever ſituated, namely, their being always moſt violent on the ſide next to the external ſurface of the body. Thus, when inflammation invades the ſocket of a tooth, it chiefly takes place towards the cheek, and not on the inſide of the alveolary proceſs. He points out, that the ſituation, poſition, ſtructure, functions, and diſtance of the part affected from the ſource of the circulation, cauſe conſiderable variety in the progreſs and termination of all inflammation. He maintains, that parts, naturally enjoying a vigorous circulation of blood then can bear inflammation better than others in the oppoſite condition. From this obſervation, however, he excepts vital parts, which, though they may be exceedingly vaſcular, do not undergo inflammation favourably, becauſe the natural operations of univerſal health depend ſo much upon the ſoundneſs of ſuch organs. Mr. Hunter alſo endeavours to ſhew, that the depending poſition of a part ſeems to have a bad effect on inflammation, probably by retarding the return of the blood. It is one of the ſame author's principles, that new-formed parts, as many tumours and excreſcences, callus, ſcars, &c. poſſeſs leſs vitality than is the ſhare of other parts, which conſtitute a portion of the original fabric of the body: hence, when inflamed, they are exceedingly apt to be deſtroyed by ulceration, or mortification.

When an inflammation is of trivial extent, and not ſeriouſly painful, the effects of the complaint are altogether local. In the contrary caſe, the whole circulation partakes in the excitement, and the inflammatory fever occurs.

The blood, taken from a patient labouring under inflammation, is well known by all medical practitioners to exhibit peculiar appearances. The blood, when it has eſcaped out of the living veſſels, ſpontaneouſly ſeparates into two diſtinct parts, the ſerum and the craſſamentum. The laſt is a compound ſubſtance, conſiſting chiefly of coagulating lymph and red globules, the moſt heavy ingredients in the blood. Now, it is to be obſerved, that blood, taken away from perſons affected with inflammation, is longer in coagulating, and coagulates more firmly, than when drawn from people in other circumſtances. Hence the red globules, which are very heavy, not being ſo ſoon entangled in the lymph, deſcend by their gravity more deeply from its ſurface, which, being in this manner more or leſs diveſted of the red colouring matter, is, from its appearance, termed the *buffy coat*, or *inflammatory cruſt*. The firmer and more compact coagulation of the lymph compreſſes out an unuſual quantity of ſerum from it, and the ſurface of the *ſizy* blood, as it is frequently called, is often formed into a hollow, the edges being drawn inwards. Theſe changes in the blood are, in ſome caſes, a more infallible proof of the exiſtence of inflammation than the pulſe itſelf. At the ſame time, it is probably only a criterion of ſome unuſual operation going on in the ſyſtem; for the blood, taken away from pregnant women, is always found to exhibit the above appearances, a circumſtance which ſhould always be recollected. In peritoneal inflammation, the patient ſometimes ſeems to be in the moſt feeble ſtate, and the pulſe, abſtractedly conſidered, would rather induce the practitioner to employ tonics and ſtimulants, than evacuations; but ſhould the continuance, or exaſperation of the diſorder, or any other reaſon, lead the ſurgeon to uſe the lancet, then the *buffy coat*, the *concave ſurface* of the blood, and the *large quantity of ſerum*, clear away all doubt concerning the exiſtence of inflammation. But every practitioner ought to bear in his mind, that, beſides pregnant women, there are a few anomalous conſtitutions met with, where the blood, taken away by the lancet, always exhibits the foregoing peculiarities, though inflammation may not prevail.

We ſee three very remarkable effects follow the prevalence of inflammation; *viz*. adheſions of parts of the body to each other; the formation of pus, or ſuppuration; and ulceration, a proceſs in which the lymphatics are more concerned than the blood-veſſels. Hence Mr. Hunter termed the different ſtages of inflammation the *adheſive*, the *ſuppurative*, and the *ulcerative*.

All parts of the body are not equally liable to each of the preceding conſequences. It was remarked by Mr. Hunter, that in the cellular membrane, and in the circumſcribed cavities, the adheſive ſtage takes place more readily than the others; ſuppuration may be ſaid to follow next in order of frequency; and, laſtly, ulceration. Whenever mucous membranes are affected, the ſuppurative inflammation comes on more readily, than either the adheſive or the ulcerative. Here adheſions, which originate from the ſlighteſt degree of inflammation in other ſituations and ſtructures, can only be produced by the moſt violent kind. Indeed, ulceration is much more frequently met with upon mucous ſurfaces than adheſions. The cellular membrane appears to be much more ſuſceptible of the adheſive inflammation than the adipoſe, and much more readily paſſes into the ſuppurative. Thus, we ſee the cellular ſubſtance, connecting the muſcles together, and the adipoſe membrane to the muſcles, inflaming and ſuppurating, and the matter ſeparating the muſcles from their lateral connections, and even the fat from the muſcles, while the adipoſe ſubſtance and the ſkin are only highly inflamed. Yet, it muſt be allowed, that in ſituations where fat abounds, we very frequently meet with abſceſſes. This is ſo much the caſe, that Mr. Bromfield accounted the fat a more common nidus for collections of matter, than the cellular ſubſtance itſelf. Thus abſceſſes about the anus, mammæ, &c. are remarkably frequent. When we ſpeak of the fat inflaming and ſuppurating, we ſhould rather ſay, that the membranous cavities containing this ſecretion are ſo affected; for, fat itſelf has no veſſels, principle of life, nor action of its own, and, conſequently, cannot be ſuppoſed to be capable of undergoing inflammation and ſuppuration.

Parts of the body, which lie deeply from the ſurface, but more particularly ſuch as are known by the name of vital, are readily affected with the adheſive inflammation. That they are not ſo much diſpoſed to ſuppurate as the ſuperficial parts are, is ſtrikingly illuſtrated in caſes of extraneous bodies, which, if deeply lodged, only produce the adheſive inflammation. By this proceſs a cyſt is formed, in which the foreign body lies, without much inconvenience to the patient, and may even change its ſituation, without ſeriouſly diſturbing the parts through which it paſſes. But no ſooner does it approach the ſkin, than abſceſſes immediately ariſe.

Much might be ſaid concerning the difference of the pulſe in the various caſes of inflammation. Thus, when any part of the ſurface of the body is affected with a certain degree of phlegmonous inflammation, the pulſe is generally full, frequent, and ſtrong. When the peritoneum and bowels are inflamed, it is very quick and ſmall, &c. We ſhall not, however, enlarge upon this topic, as the ſtate of the pulſe, in the ſeveral caſes, will be noticed in the many articles of this work appropriated to the conſideration of inflammatory diſeaſes.

According to Mr. Hunter, the ſuſceptibility of the body for inflammation is of two kinds; the one *original*, conſtituting a part of the animal economy, and beyond the reach of human inveſtigation; the other *acquired* from the influence of climate, habits of life, and ſtate of the mind over the conſtitution. The firſt kind of ſuſceptibility, being innate, cannot be diminiſhed by art; the ſecond may be leſſened by the mere avoidance of the particular cauſes upon which it depends. Theſe latter might be named *prediſpoſing*.

With regard to the *remote*, *exciting*, or *occaſional* cauſes of inflammation, they are infinite in number; but very eaſy of comprehenſion, becauſe moſt of them are referrible to two general claſſes. The firſt includes all ſuch as operate, by their ſtimulant or chemical qualities, as, for inſtance, heat, cantharides, ſulphuric acid, aqua ammoniæ puræ, &c. The ſecond embraces ſuch as act mechanically, as bruiſes, wounds, fractures, &c.

The principle on which cold becomes an exciting cauſe of inflammation, is yet conteſted among ſurgical writers, and may ſtill be conſidered as not decidedly known.

Fevers would ſometimes appear to be the exciting cauſes of inflammation. The local affection, thus originating, is often called *critical*, and is ſuppoſed by many to be the means, by which a ſtop is put to the conſtitutional indiſpoſition. Strong injunctions are, therefore, given not to repreſs an inflammation of this kind, leſt the method ſhould be productive of ſome worſe and even fatal diſorder. We have always conſidered this mode of reaſoning unſatisfactory, and ſhould have little apprehenſion of any real evils, which might ariſe from the attempt to diminiſh an inflammation, that appears as a conſequence of a fever.

The following obſervations reſpecting the proximate cauſe of inflammation, are taken from Mr. S. Cooper's Dictionary of Practical Surgery.

Numerous opinions have been entertained upon this ſubject; but almoſt every theory has been built upon the ſuppoſition of there being ſome kind of obſtruction in the inflamed part.

While the circulation of the blood was unknown, and the hypothetical notions of the power of the liver, in preparing and ſending forth this fluid continued to prevail, it is not aſtoniſhing, that the theories of phyſic ſhould be exceedingly imperfect. So fully perſuaded were phyſicians of the exiſtence and influence of different humours and ſpirits, and ſo little did they know of the regular and conſtant motion of the blood, that they believed in the poſſibility of depoſitions and congeſtions of the blood, the bile, or lymph; and acknowledged theſe as the cauſe of inflammation. Their anatomiſts taught them, and their profeſſors of phyſic ſupported the opinion, that the liver was the centre of the vaſcular ſyſtem, from which the blood went forth by day to the extremities, and returned again by night. If then any peccant matter irritated the liver, the blood was ſent out more forcibly; and if, at the ſame time, any part of the body were weakened, or otherwiſe diſpoſed to receive a greater quantity of fluid than the reſt, then a ſwelling was produced by the flow of humours to this place. Fluxions, or flows of humour to a place, might happen either from weakneſs of the part which allowed the humours to enter more abundantly, or from the place attracting the humours, in conſequence of the application of heat or other agents.

The peculiar nature of the ſwelling thus occaſioned was ſuppoſed, by the ancients, to depend upon the kind of humour. Blood produced the true phlegmon, bile, eryſipelas, &c.

The ancient phyſicians alſo entertained an idea, that the blood and humours might ſlowly ſtagnate in a part, from a want of expulſive power, and this affection was termed a *congeſtion*, while the expreſſion *fluxion* or *defluxion* was uſed to denote any ſwelling ariſing from the ſudden flow of humours from a diſtant part. The firſt was formed gradually without much pain, or the feeling of pulſation, and ran its courſe ſlowly; the ſecond appeared ſuddenly, was very painful, had a pulſatory feel, and was rapid in its progreſs. The ancients, who ſuppoſed that the blood had very little motion, and that its courſe could be eaſily directed or changed, recommended bleeding from ſome part which was remote from a recent inflammation, by which they imagined that the current of blood was altered, and a *revulſion* made. A revulſion was alſo made by raiſing a tumour in ſome other part, by means of ligatures, cupping-glaſſes, &c. or by giving nature an opportunity of diſcharging the humours from diſtant parts, by applying leeches or bliſters. Hence ſinapiſms were applied to the feet in diſeaſes of the ſuperior parts.

When blood was drawn from the vicinity of the fluxion, or congeſtion, the mode was called *derivation*, which only differed from *revulſion* in the diſtance to which the humour was drawn being leſs.

We ſhall not enter further into an account of the practice of the ancients in the treatment of inflammation; but ſhall refer the reader to what Mr. Burns has written on the ſubject. Our preſent object is only to trace the leading doctrines which have at different times prevailed, reſpecting the proximate cauſe of inflammation.

From the theories of *fluxion* and *congeſtion*, which were quite incompatible with the laws of the circulation of the blood, we turn our attention to the doctrine of *obſtruction*.

Boerhaave inculcated, (Aph. 375 et ſeq.) that inflammation was cauſed by an obſtruction to the free circulation of the blood in the minute veſſels, and this obſtruction, he ſuppoſed, might be cauſed by heat, diarrhœa, too copious flow of urine and ſweat, or whatever could diſſipate the thinner parts of the blood and produce a thickneſs or viſcidity of that fluid. When the lentor did not exiſt before the production of inflammation, he imagined, that the larger globules of the blood got into the ſmall veſſels, and thus plugged them up. When, for inſtance, the perſpiration was ſtopped, the fluid, being retained, dilated the veſſels, and allowed ſome of theſe miſchievous globules to enter, and produce a more permanent obſtruction. This circumſtance was termed an *error loci*, and was one of the chief cauſes aſſigned for inflammation. The obſtruction, whether cauſed by *viſcidity* or an *error loci*, was imagined to occaſion a reſiſtance to the circulation in the part affected; hence increaſed it in the other veſſels, proving an irritation to the heart, and augmenting the force or attraction of the blood in that part of the veſſel which was behind the obſtruction. This cauſed heat and pain, while the accumulation of the blood produced redneſs; which three ſymptoms are the eſſence of the diſeaſe. Beſides *obſtruction*, Boerhaave alſo brought into the account an *acrimonious ſtate of the fluids*, which rendered reſolution out of the queſtion, and gangrene likely to follow. Aph. 388.

The viſcidity of the blood cannot be admitted as the proximate cauſe of inflammation; becauſe we have no proof that this ſtate ever exiſts; or, granting that it did, it would not explain the phenomena. Were a viſcidity to occur, it would exiſt in the whole maſs of blood, would affect every part of the body alike, and could not be ſuppoſed to produce only a local diſorder. How alſo could ſuch a lentor be produced by cauſes which bring on inflammation ſuddenly, without there being time for changes of the fluids to take place?

With regard to the doctrine of *error loci*, or of red globules going into veſſels, which did not formerly tranſmit them, the fact muſt be admitted, at the ſame time, that the concluſion is denied. When the eye becomes inflamed, the tunica conjunctiva is ſeen with its veſſels full of red blood, which in health is not the caſe; but this redneſs never appears until the inflammation has commenced; and muſt, therefore, be conſidered as an effect, not a cauſe. Nor can this error loci occaſion any obſtruction in theſe veſſels; for if they be divided, the blood flows freely, which ſhews, that they are large enough to allow an eaſy circulation.

Boerhaave's theory of obſtruction was too circumſcribed, and too mechanical; it reduced all inflammations to one ſpecies. The only diſtinctions which could have ariſen, muſt have proceeded from the nature of the obſtruction itſelf. This doctrine could never account for the action of many ſpecific diſeaſes and morbid poiſons.

As for the ſuppoſition of the co-operation of an *acrimony of the fluids*, the proportion of the ſaline matter of the blood has never been proved to be greater in this, than in any other ſtate of the body. Even were a general diſorder of this kind to be admitted, no rational explanation of the proximate cauſe of local inflammation could be deduced from it.

Dr. Cullen attributed the proximate cauſe of inflammation to a "ſpaſm of the extreme arteries ſupporting an increaſed action in the courſe of them." This theory only differs from that of Boerhaave in the cauſe which is aſſigned for the obſtruction. Some cauſes of inequality in the diſtribution of the blood, may throw an unuſual quantity of it upon particular veſſels, to which it muſt neceſſarily prove a ſtimulus. But, farther, it is probable that, to relieve the congeſtion, the vis medicatrix naturæ increaſes ſtill more the action of the veſſels; and which, as in all other febrile diſeaſes, it affects, by the formation of a ſpaſm on their extremities. "A ſpaſm of the extreme arteries, ſupporting an increaſed action in the courſe of them, may, therefore, be conſidered as the proximate cauſe of inflammation; at leaſt, in all caſes not ariſing from direct ſtimuli applied; and even in this caſe, the ſtimuli may be ſuppoſed to produce a ſpaſm of the extreme veſſels."

The inconſiſtencies in Cullen's theory are very glaring. The congeſtion or accumulation of blood, which is only an effect or conſequence of inflammation, is ſet down as the cauſe of the ſpaſm of the veſſels, to which ſpaſmodic conſtrictions Cullen, ſtrangely enough, aſſigns the name of proximate cauſe. The ſpaſmodic contraction of the extremities of the veſſels, inſtead of propelling the accumulated quantity of blood, would render the paſſage of the blood from the arterial into the venous ſyſtem ſtill more difficult. Spaſmodic conſtriction of the ſmall veſſels is ſo far from being a ſatisfactory explanation of the proximate cauſe of inflammation, that even tying a large veſſel does not of itſelf bring on the affection. Phlegmon is alſo attended with an effuſion into the cellular ſubſtance from the extremities of the arteries; a circumſtance not eaſily explained upon the principle of obſtructed circulation. See Burns on Inflammation.

We ſhall now notice the celebrated, and very original opinions promulgated on this ſubject by the famous John Hunter. According to him inflammation is to be conſidered only as a diſturbed ſtate of parts, which requires a new, but ſalutary mode of action, to reſtore them to that ſtate, wherein a natural mode of action alone is neceſſary. From ſuch a view of the ſubject, therefore, inflammation, in itſelf, is not to be conſidered as a diſeaſe, but as a ſalutary operation, conſequent either to ſome violence, or ſome diſeaſe. Elſewhere, the author remarks, the act of inflammation is to be conſidered as an increaſed action of the veſſels, which, at firſt, conſiſts ſimply in an increaſe or diſtention beyond their natural ſize. This increaſe ſeems to depend upon a diminution of the muſcular power of the veſſels, at the ſame time that the elaſtic power of the artery muſt be dilated in the ſame proportion. This is, therefore, ſomething more than ſimply a common relaxation; we muſt ſuppoſe it an action in the parts to produce an increaſe of ſize, to anſwer particular purpoſes, and this Mr. Hunter would call an act of dilatation. The whole is to be conſidered as a neceſſary operation of nature. Owing to this dilatation, there is a greater quantity of blood circulating in the part, which is according to the common rules of the animal economy; for, whenever a part has more to do than ſimply to ſupport itſelf, the blood is there collected in larger quantity. The ſwelling is produced by an extravaſation of coagulable lymph, with ſome ſerum; but this lymph differs from the common lymph, in conſequence of paſſing through inflamed veſſels. It is this lymph which becomes the uniting medium of inflamed parts; veſſels ſhoot into it, and it has even the power of becoming vaſcular itſelf. The pain proceeds from ſpaſm. The redneſs is produced either by the arteries being more dilated than the veins, or becauſe the blood is not changed in the veins. When, after an injury, a part cannot be reſtored to health by inflammation alone, or by adheſion, then ſuppuration, as a preparatory ſtep to the formation of granulations, and the conſequent reſtoration of the part, takes place. The veſſels are nearly in the ſame ſtate as in inflammation; but they are more quieſcent, and have acquired a new mode of action. See Hunter on the Blood, Inflammation, &c.

An increaſed action of the veſſels is now almoſt univerſally regarded as the proximate cauſe of inflammation. This opinion derives ſtrong ſupport from a review of the ſeveral exciting cauſes of the affection, which, being in general of an irritating nature, muſt, when applied to living or ſenſible parts, occaſion a preternatural exertion of their veſſels. The method of cure tends alſo to confirm the common ſentiment concerning the proximate cauſe of inflammation. See Dictionary of Practical Surgery.

Treatment of Inflammation.—According to the preceding views of the ſubject, the firſt and principal object to be aimed at in the treatment of inflammation, is to diminiſh that immoderate action of the arteries, which exiſts in ſo conſpicuous a degree. There are ſeveral means conducive to this end; but that which demands primary attention, and, indeed, which ſeems to be indicated by common ſenſe, is to remove, if poſſible, whatever conſtitutes the remote or exciting cauſe of the inflammation. Thus, ſuppoſing the eye were to inflame in conſequence of a ſmall inſect lodging under the eyelids, how obvious would be the propriety of immediately taking away the ſource of irritation? If the irritation of a thorn or ſplinter ſhould excite inflammation, who would not of his own accord endeavour to extract the extraneous ſubſtance? When the affection is excited by extravaſated urine, by preſſure, friction, ſtimulating applications, &c. the ſurgeon often has it in his power to render moſt eſſential ſervice, by removing at once what excites and keeps up the complaint. Frequently, the exciting cauſe is tranſient in its operation, and yet, the inflammation cannot be prevented from running a certain courſe. Thus, many kinds of external violence are inflicted in a moment; but inflammation muſt follow, and go through its operations, though the duration of the circumſtance which gave riſe to the proceſs has ceaſed. The living ſolids demonſtrate, in theſe inſtances, a kind of reaction. Since, therefore, the removal of the ſtimulus which excites inflammation will not always put an immediate ſtop to the complaint, however it may tend to alleviate it, we are generally called upon to moderate, by other means, the increaſed vaſcular action.

There are few perſons ſo entirely ignorant of the ſubject before us, as not to know that bleeding is one of the moſt powerful means of counteracting inflammation. This well known fact, which has obtained the aſſent of the moſt celebrated phyſicians and ſurgeons in every age and country, can hardly fail to be quite congenial with ſuch ideas and expectations as are naturally impreſſed upon the mind by a deſcription of the diſorder. Indeed, one principal effect of the increaſed action of the veſſels, is the tranſmiſſion of a larger quantity of blood through the inflamed part. The propriety of endeavouring, therefore, in moſt caſes, to diminiſh this determination of blood to the ſeat of the inflammation, cannot be doubted. The chief mode of accompliſhing this object is by general and topical bleeding. This evacuation is called *general*, when the blood is taken from a large veſſel, at a diſtance from the inflamed part; *local* or *topical*, when the blood is evacuated by leeches, ſcarifications, or cupping, from the veſſels which are near, or belong to the inflamed part. General bleeding is not ſo invariably proper as topical.

cal. Inflammation is a local affection, and therefore muſt particularly require local curative means. Objections have been urged againſt topical bleeding, except when the ſkin, over and near the inflamed part, is itſelf free from the inflammation. However, moſt ſurgeons in this country think otherwiſe; they put leeches on the inflamed ſkin, and even ſcarify the dilated veſſels of the conjunctiva, in caſes of ophthalmy, as we think, with decided good effect. It is alſo an incontrovertible truth that bleeding is generally more effectual, the nearer the evacuation is made to the ſeat of the inflammation. But it is not always in our power to take away a ſufficient quantity of blood in this manner. Many inflammations muſt be immediately checked, or the patient is deſtroyed. Therefore, when inflammation affects a part of ſuch conſequence in the animal economy that it cannot undergo much diſturbance, without life itſelf being endangered, the ſurgeon is not to be ſatisfied with local meaſures. Thus, when the brain, the lungs, the ſtomach, the bowels, &c. are inflamed, the inflammation, unleſs ſuddenly arreſted, will inevitably end in death. Alſo, when the inflamed parts are endued with inferior powers of recovery, it is often neceſſary to have recourſe to general as well as topical bleeding; as in inflammation of a joint. When inflammation is ſituated in an organ, where ſuppuration would certainly deſtroy its uſes, it is likewiſe adviſable to moderate the local affection, even at the expence of the whole ſyſtem. Ophthalmy is a caſe of this kind. Moreover, it ought to be well underſtood that every conſiderable and extenſive phlegmonous inflammation, whereſoever ſituated, ought always to be reſiſted by general bleeding.

There is no utility in bleeding, when the inflammation and fever are trivial, and the cauſe of the diſorder can be entirely removed. Such evacuation muſt often be hurtful and dangerous, when the patient is much debilitated by previous indiſpoſition, extreme age, or any other circumſtance. The ſymptomatic fever, attendant on inflammation, can ſeldom be of itſelf a juſt ground for bleeding, as it conſtantly increaſes and ſubſides with the local affection. We are, therefore, to be principally guided by the ſtate of the inflammation. Bleed with a view of diminiſhing this, but never for the ſole purpoſe of leſſening the fever.

It is a principle very generally acknowledged by ſurgeons, that the efficacy of bleeding is greater the ſooner it is practiſed, the nearer it is done to the part affected, and the more ſuddenly the blood is diſcharged. Hence, when an organ, like the brain, is inflamed, and it is an object of infinite moment to put an immediate check to the inflammation, the ſurgeon ſhould take away in the firſt inſtance ſixteen or twenty ounces of blood, if poſſible, from the temporal arteries; but if that quantity cannot be thus procured, the deficient proportion ought to be taken from the arm.

Another plan, calculated to check and diminiſh inflammation, and which is neceſſary in almoſt all caſes, is to give the patient mild aperient medicines, ſuch as Epſom ſalt, Glauber's ſalt, magneſiæ ſulphas, &c. Strong draſtic purgatives, by their irritation on the conſtitution, are ſeldom allowable, and almoſt always prove hurtful. Gentle purging is even more invariably proper, in all caſes where inflammation already exiſts, or is to be apprehended, than bleeding; for this latter evacuation is productive of more laſting weakneſs, and therefore, in ſlight caſes, and weak habits, is generally diſpenſed with. Purging probably counteracts inflammation, firſt by increaſing the ſecretion of the bowels, ſo as to leſſen the quantity of the circulating fluids; and ſecondly, by ſpecifically diminiſhing every operation going on in the body, and among others, inflammatory action.

In many inſtances, the effect of the aperient medicines is to be promoted with clyſters. Indeed, there are ſome examples, where the latter are ſafer than purgatives given by the mouth: when the peritoneum and bowels are inflamed, the prudent ſurgeon is often afraid to preſcribe any very active opening medicines. Perhaps he ventures to exhibit half an ounce of the oleum ricini, which frequently does not take effect, although the doſe be repeated, until aſſiſted with a clyſter.

Antimonial medicines have acquired conſiderable reputation in numerous caſes of inflammation, and, as far as we can judge, they are really of eminent ſervice. Nauſeating doſes of antimonium tartarizatum prove advantageous in ſeveral ways; they relieve that oppreſſive dryneſs of the ſkin, which accompanies the fever attendant on ſevere local inflammation; they promote all the excretions; and they diminiſh the increaſed action of the inflamed part. The latter effect is produced, becauſe, whenever an inclination to ſickneſs prevails, the ſympathy of the whole conſtitution with the ſtomach is ſo intimate, that the ſyſtem is immediately thrown into a temporary ſtate of debility, every conſiderable operation in the machine becoming lowered, and, among others, the proceſs of inflammation. When the inflammation is dangerous, and there is urgent reaſon for putting an immediate check to it, the employment of antimonials ought never to be neglected. Thus, when the brain or its membranes are affected with inflammation, it is uſual to exhibit ſmall doſes of antimony.

Opium is not preſcribed in caſes of common inflammation, unleſs the ſeverity of the pain render this medicine indiſpenſably neceſſary; for it is generally conſidered as a powerful ſtimulant, and therefore hurtful in regard to the local complaint. Inſtances, however, certainly do preſent themſelves, in which opium is proper. Procuring the patient eaſe and ſleep, during the violence of many ſevere inflammations, is an object of the higheſt importance; and, it may be queſtioned whether the inflammation itſelf would not be aggravated more by leaving the patient to all his pain and reſtleſsneſs, than by making an attempt to diminiſh his ſufferings, and lull him to ſleep by opiates. One thing ſeems certain, that if opium is to be given in caſes where pain and inflammation exiſt, it ſhould be preſcribed in an adequate doſe. Thus, after any great operation, ſuch as an amputation, the removal of a breaſt, &c. the ſurgeon ſhould give from twenty-five to forty drops of the tinctura opii; ſmall doſes of opium, in ſuch caſes, always have the effect of ſeriouſly increaſing the reſtleſsneſs, fever, &c. inſtead of affording eaſe, and procuring ſleep.

The patient's regimen and diet are to be low; no ſpirits nor fermented liquors are allowable; and when the inflammation is at all extenſive, or ſuch as to be of conſequence, the patient ſhould abſtain from eating meat, and live on thin broths, barley-water, tea, &c. The practitioner would in vain make depletions in order to ſtop an inflammation, while his patient was living upon groſs, hot, ſtimulating diſhes. On the contrary, when the regimen and diet are ſuch as they ought to be, the patient will do with leſs evacuations, and his health will not be ſo much injured by the requiſite treatment. He ſhould be adviſed to drink plentifully of diluent cooling beverages, like lemonade and acidulated barley-water. Oranges, ſtrawberries, ſaline draughts, &c. may be permitted, as being exceedingly grateful to patients, who are feveriſh and thirſty, from being affected with any ſerious degree of inflammation. The patient's chamber ſhould be kept cool, nor ought he to be covered with two much bedding. The antiphlogiſtic regimen, moreover, requires perfect repoſe both of body and mind.

With regard to the topical applications, theſe are generally either cold aſtringent lotions, or elſe warm relaxing emollients. Heat is well known to promote and increaſe all animal actions, and muſt therefore tend to keep up and augment the proceſs of inflammation. Hence ariſes the indication to diminiſh the heat of the part affected, by making uſe of cold topical applications, and maintaining a continual evaporation from the inflamed ſurface. The common plan is to dip linen in the ſaturnine lotion, and after folding it once or twice, lay it all over the part affected, taking care afterwards to keep it conſtantly wet with the application. In ſome inſtances cold water will anſwer every purpoſe; in others the aqua ammoniæ acetatæ, or lotions of the ſulphate of zinc, alum, &c. may be employed. Poultices made with linſeed-meal and water, or with bread and milk, are the ordinary emollient applications when ſuch are conſidered proper. Thoſe of the firſt kind are frequently preferable to the latter, which are apt to turn ſour and acquire an irritating quality, a circumſtance of high importance where the cuticle is detached, ulceration is preſent, or the part is exquiſitely ſenſible. When poultices are uſed, fomentations are alſo frequently proper, as having in all ſevere caſes a great effect in leſſening the pain. Likewiſe, when ſuppuration is unavoidable, they accelerate the cure by promoting the formation of matter, and haſtening its approach to the ſurface of the body. The common method is to dip flannels in a decoction of chamomile flowers, or white poppy heads, wring them, and apply them very warm to the inflamed part.

In diſcriminating the caſes which require cold applications from others to which warm ones are moſt ſerviceable, the practitioner ſhould always bear in mind, that when ſuppuration is inevitable, it is invariably moſt advantageous to diſcontinue cold aſtringents without delay. In general, where the chance of the inflammation being reſolved is great, cold applications are beſt; but ſometimes the choice of the topical remedies muſt be partly regulated by the patient's feelings. There are ſome patients who ſeem to derive moſt eaſe from cold applications: there are others who appear to experience moſt comfort from cold ones. The latter remedies ought perhaps rather to have the preference, when the proſpect of preventing ſuppuration is fair and rational, and when at the ſame time they afford as much eaſe as poultices.

In technical language, inflammation is ſaid to have different terminations. When the redneſs, ſwelling, heat, and pain, all gradually ſubſide, without any formation of matter, the caſe ends in what is termed *reſolution*, which is the moſt favourable event that can happen.

In ſome inſtances, a change takes place in the action of the veſſels of the inflamed part, and they aſſume the power of ſecreting pus, or matter. Thus an abſceſs is formed, and the caſe (ſurgically ſpeaking) terminates in *ſuppuration*.

In certain examples, ulceration is a direct conſequence of inflammation, but in general an abſceſs precedes the ſore.

The laſt termination of inflammation, to be noticed here, is in *mortification*, which is the worſt, but happily the leaſt frequent reſult of common caſes. See GANGRENE, SUPPURATION, &c.

For an account of particular kinds of inflammation, ſee ERYSIPELAS, ANTHRAX, CARBUNCLE, FURUNCULUS, SCROFULA, LUES VENEREA, &c.

The inflammations of various parts of the body are alſo treated of under diſtinct heads. For inflammation of the eye, ſee OPHTHALMY; for that of the parts about the anus, ſee FISTULA *in Ano*; for that of the dura mater, ſee INJURIES *of the Head*; for that of the teſticle, ſee HERNIA *Humoralis*; for that of the fingers, ſee WHITLOW, &c. &c.

INFLAMMATION *of the Womb*. See HYSTERITIS.

INFLAMMATION, *Spontaneous*, of earthy matters, in *Mining*. It is a curious and important fact, that ſeveral pyritic and bituminous thin ſtrata which are found accompanying the coal-ſeams in ſome ſituations, will, on being thrown out or expoſed to the air in the works, heat and take fire. This ſeems particularly the caſe in the thick coal-ſeam about Dudley in Staffordſhire, as mentioned by Mr. Keir in Shaw's Hiſtory of Staffordſhire. In different parts of Derbyſhire there are alſo thin ſtrata of duns, tows, &c. which thus intumeſce and take fire in the coal-works, as at Heanor, Derby-hall and other pits, which are particularized by Mr. Farey in his Report on this county, vol. i. p. 348.

INFLAMMATORY DISEASES, in *Medicine*, are all thoſe diſeaſes in which any part or organ of the body is affected with inflammation, as above deſcribed; but theſe terms, in the general acceptation, imply more particularly thoſe acute and ſevere inflammations which excite a degree of febrile commotion in the ſyſtem. In addition to thoſe juſt enumerated, with references, the gout, acute rheumatiſm, eryſipelas, &c. may be included under the claſs of inflammatory diſeaſes, and, together with them, conſtitute, in fact, a diſtinct Order, in the ſyſtem of our beſt noſologiſt, Dr. Cullen, under the title of *Phlegmaſiæ*; namely, the ſecond order, of the firſt claſs, *Pyrexiæ*, or *Febrile* diſeaſes. See his Noſol. Method.

We judge of the preſence of an internal inflammatory diſeaſe by the occurrence of the following congeries of ſymptoms; namely, when, together with a ſtate of *fever*, there is a *fixed pain* in any internal part, attended with ſome *interruption* in the exerciſe of *its functions*. It is to be obſerved, that the concurrence of all theſe ſymptoms is neceſſary to prove the exiſtence of active inflammation in any organ, and that the occurrence of any one or two of them may originate from other cauſes than inflammation. Thus pain may ariſe from a ſpaſmodic contraction of the muſcular fibres of the part, and it may be moveable, and paſs from one part to another; fever may ariſe with or without pain; and the functions of an organ may be impeded without either pain or fever. In none of theſe caſes are we to conclude that active inflammation is going on. We may illuſtrate this with reſpect to inflammation of the lungs, or *peripneumony*. This diſeaſe is known to be preſent, when, together with general *fever* (*i. e.* a frequent pulſe, hot ſkin, thirſt, &c.), there is a fixed *pain* in ſome part of the cheſt, *cough*, and *difficulty of breathing*. (Cullen, Noſol. Meth. Claſs i. Ord. ii. Gen. 11.) Now *fever* occurs from many other cauſes, and without theſe other ſymptoms; in which caſe no pulmonic inflammation is judged to be preſent. *Pain* may be felt in the cheſt when there is neither cough nor fever, nor difficult reſpiration, as in the caſe of rheumatiſm in the intercoſtal muſcles, the diaphragm, or perhaps the mediaſtinum, or in the caſe of partial or general ſpaſm in theſe muſcles. It may be alſo felt, with difficulty of breathing, but without fever, as in the caſe of ſpaſm of the diaphragm, in hydrothorax, or in angina pectoris: or it may concur with fever when there may be no cough, as ſometimes happens when the liver is inflamed on the ſurface contiguous to the diaphragm. Again, there may be an impeded function (*i. e.* in this caſe *difficulty of reſpiration*) without fever or pain, as in many caſes of aſthma and chronic dyſpnæa, connected with a ſpaſmodic conſtriction of the bronchial paſſages, or a conſiderable ſecretion of mucus into the cells and bronchial tubes. But where there is inflammation in the lungs, there is neceſſarily, in the firſt place, a ſymptomatic *fever;* in the next, from the congeſtion and over-diſtention of the veſſels of the inflamed organ, there is a fixed *pain*, and alſo a difficulty of admiſſion of air into the compreſſed cells, *i. e. difficult breathing;* and the irritation upon the nerves of the bronchiæ, by this congeſtion, as well as by the mucus ſecreted, neceſſarily excites *cough*.

Theſe concurring phenomena, then, of pain and impeded function in any organ, with general fever, are the diagnoſtic ſymptoms of all internal inflammatory diſeaſes. But there are ſtill other phenomena which indicate the degree of violence of the inflammation which is going on. Theſe are principally the other conditions of the pulſe, beſides its frequency, and the appearance of the blood drawn from the veins. Where an acute inflammation ſubſiſts, the pulſation of the heart and arteries is generally very vigorous; ſo that the pulſe at the wriſt ſtrikes againſt the finger with a conſiderable force, and with a ſharpneſs of ſtroke which elevates the finger, compreſſing the artery, even when firmly held on it. The terms hard, ſtrong, and ſharp, have been uſed to denote this vigorous pulſation of the artery. The degree of hardneſs, ſtrength, or ſharpneſs of the pulſe, however, varies greatly, not only according to the violence of the diſeaſe, but to the vigour of the patient's natural conſtitution; and it differs alſo according to the peculiar ſtructure of the organ inflamed; all of which circumſtances muſt be taken into the conſideration of the phyſician before he decide upon the practical treatment which he ſhall adopt. Even in the moſt ſevere inflammation, which a very delicate habit is capable of undergoing, the pulſe may be leſs full and ſtrong than in a ſlight febrile affection in a robuſt habit; but there is generally a degree of ſharpneſs in the ſtroke of the pulſe, even in a feeble habit under the excitement of acute inflammation, which the *tact*, acquired by a little experience, enables the phyſician to eſtimate. Beſides, in ſuch caſes, the degree of pain and of impeded function, and the ſtate of the pulſe, mutually illuſtrate each other. If the pain has remained fixed and ſevere for many hours, and the function of the ſuffering organ is greatly deranged, although the pulſe may betray but a moderate degree of ſharpneſs or hardneſs in a habit not originally ſtrong, the proper evacuations for the cure of inflammation muſt be conſidered as indicated. This is particularly neceſſary, as we have juſt hinted, in reſpect to certain organs. When there is an acute inflammation in the *lungs* or *liver*, and eſpecially when the enveloping membranes are affected, the pulſe is perhaps invariably characterized by hardneſs and ſtrength. (See Hepatitis and Pleurisy.) But when the *ſtomach* is inflamed, the pulſe is often without any conſiderable hardneſs, and generally ſmall, but very frequent. In this caſe, therefore, the exiſtence of acute inflammation might be overlooked, if we judged principally from the pulſe; and it is neceſſary to compare the ſtate of the pulſe with the degree of fixed burning pain in the ſtomach, and the ſudden increaſe of that pain, as well as the vomiting which is excited by any thing whatever that is taken into the ſtomach, in order to aſcertain the nature of the diſeaſe. See Gastritis.

The other circumſtance, which has been mentioned as aiding us in diſtinguiſhing the degree of violence of any internal inflammation, is the appearance of the blood drawn from the veins. When the lancet is uſed in inflammatory diſeaſes, the blood, which is drawn, after ſtanding ſome time in any veſſel until coagulation has taken place, exhibits, on the ſurface of the *coagulum*, a thick gelatinous ſubſtance, without any admixture of red blood: this has been variouſly termed the *buffy coat*, or ſimply the *buff*, the *inflammatory cruſt*, &c.; and has been conſidered as a proof of the exiſtence of inflammation, and as a teſt, in a great meaſure, of the ſeverity of the diſeaſe. It is certain, that this buffy cruſt is commonly found in pleuriſy, peripneumony, hepatitis, acute rheumatiſm, &c., and is not ſeen where blood flows from a perſon in ordinary health. It ſeems to ariſe from a difference in the mode of coagulation, ſo that the red particles ſubſide and leave the upper portion of the coagulating lymph untinged; and not to conſiſt of a morbid humour in the blood, as the humoral pathologiſts believed. But experience has taught us, that the buffy ſtate of the blood is not a criterion, by which the neceſſity or propriety of blood-letting can be determined in diſeaſes. For, not to mention the abſurdity of relying upon a teſt, which requires the practice to be adopted, to ſome extent or other, before its propriety can be aſcertained; (a doctrine which has often led to the folly of taking away a little blood, "to ſee how it looked,") obſervation has proved, that the blood is actually often in the condition to ſhew the buffy coat, where no inflammatory action is going on, and where, although a certain degree of inflammatory action may be preſent, yet it will not be removed by blood-letting; but if the blood-letting be repeated, the patient may be deſtroyed before the buffy coat on the blood will diſappear. Thus the buffy coat is almoſt invariably ſeen on blood drawn from women in a ſtate of pregnancy; it is likewiſe ſeen on that, which is taken from perſons labouring under hectic fever, from pulmonary conſumption; nay, it has been obſerved on the blood drawn from patients affected with the *typhus* fever, and with *ſcurvy* (ſee Fourcroy, Connoiſſ. Chimiques; alſo Blood, *morbid alterations of*,); in all which caſes we ſhould occaſion infinite miſchief, were we to conceive that this appearance indicated the neceſſity of repeating the uſe of the lancet. But, farther, it is a fact, which has not hitherto been ſatisfactorily explained, that in a violent attack of unequivocal inflammation, as of pleuriſy, if, during one bleeding, the blood be received in two or three different veſſels, the coagulum in one or two of the veſſels ſhall preſent the buffy coat, while none will appear on that in the others; and in like manner, if blood-letting be repeated two or three times, the blood of the firſt drawing ſhall exhibit no buffy cruſt, while that of the ſubſequent drawing ſhall ſhew it in large quantity. This variety has been principally attributed to the velocity with which the blood flows from the vein; thus it would appear, that the blood which trickles ſlowly down the arm, ſeldom ſhews ſo much buff, as that which flows in a full and copious ſtream. In a word, then, the appearances of the blood drawn in the cure of diſeaſes, is to be conſidered as a very imperfect guide in directing the farther uſe of the lancet, and is only to be deemed a ſecondary adjuvant in determining the proper mode of practice, in conjunction with a careful inveſtigation of the violence of the ſymptoms of the diſeaſe, its duration, and tendency, and of the age, ſtrength, and conſtitution of the patient.

In attempting to form an accurate *diagnoſis*, in regard to inflammatory diſeaſes, two difficulties preſent themſelves: the firſt of theſe is the difficulty of diſtinguiſhing the inflammation of one organ from that of another, which is contiguous to it, or in its vicinity. For inſtance, the leading ſymptoms of inflammation of the lungs, in very many caſes, are preſent in hepatitis, or inflammation of the liver, on the one hand, and in carditis, and pericarditis, or inflammation of the heart, and of the pericardium, on the other. The diſtinction, which is commonly ſuppoſed to exiſt between the inflammation of the heart and its membranous bag, and inflammation of the lungs, conſiſts in the occurrence of palpitation, ſyncope, and an irregular pulſe, in the former diſeaſe, in addition to the ſymptoms of the latter: but Dr. Cullen admits that theſe three ſymptoms are occaſionally abſent in *pericarditis*, and accords with the obſervation of Vogel, that "the ſymptoms of *carditis* are nearly the ſame as thoſe of peripneumony, but more ſevere:" *i. e.* fever, with pain in the left ſide of the cheſt, difficulty of breathing, and cough. (See Cullen, Noſol. Meth. Claſs i. Ord. ii. Gen. 13 and 11.) In like manner, theſe four diagnoſtic ſymptoms of peripneumony and pleuriſy are commonly preſent in inflammation of the liver, eſpecially when the convex ſide of that viſcus, which lies in contact with the diaphragm, is the ſeat of the inflammation: for in addition to fever, and pain in the ſide, a difficulty of breathing is occaſioned by the ſuffering, which any attempt to depreſs the diaphragm in the act of inſpiration, excited by compreſſing the inflamed liver; and a cough, which, however, is commonly dry, or unaccompanied by expectoration, but not always, and which is excited probably by the vicinity of the ſeat of irritation to the lungs. As the hepatitis proceeds, the other ſymptoms belonging to it, eſpecially the bilious tinge of the ſkin and eyes, point out clearly the ſeat of the inflammation.

It is ſatisfactory, however, to know that, in ſuch caſes of extreme ſimilarity of ſymptoms, no practical evil can ariſe from the inability to decide as to the ſeat of the diſeaſe: for, in the firſt place, the inflammation actually ſpreads, in ſome inſtances, to the contiguous organs, ſo that the ſymptoms indicative of the diſorder in both muſt neceſſarily co-exiſt; and, in the ſecond place, the inflammation requires the ſame practical meaſures to be adopted for its removal, in whatever viſcus it may be ſeated; namely, evacuations proportioned to its violence, and to the vigour of the patient.

The ſecond difficulty, in diſtinguiſhing inflammatory diſeaſes, to which we have alluded, ariſes from the occaſional ſeverity and fixed ſeat of the pain, which is attendant on cramps or ſpaſmodic diſeaſes, more eſpecially in the ſtomach and the bowels. Hence it is often extremely difficult to pronounce, whether an acute pain in the belly, for inſtance, is occaſioned by the *colic*, or by *enteritis* (inflammation of the bowels), for conſtipation accompanies both; and although a mere ſpaſmodic pain is very commonly preſent, without any acceleration of the pulſe, or febrile heat; yet when ſuch pain is extremely acute, and has continued for ſome length of time, the conſtitution begins to ſuffer from exceſſive irritation, and the pulſations of the heart and arteries are quickened; and if it ſtill continues, actual inflammation in the part is liable to enſue, ſo that what was colic in the commencement, becomes finally enteritis. It is important to diſcriminate accurately in the outſet between theſe two ſtates of pain; becauſe that, which is ſpaſmodic, may be removed by large doſes of opium, and other antiſpaſmodics; whereas the inflammatory pain would be augmented, and the diſeaſe itſelf rendered more dangerous, by the exhibition of ſuch medicines. In making this diſcrimination, the practitioner is principally guided by the hardneſs and force, or the ſoftneſs and weakneſs of the pulſe;—by the rigidity of fibre and robuſt habit, or the contrary condition of the patient;—by the unvarying intenſity and ſeat of the pain, or its occaſional remiſſions and ſlight change of place;—and by a knowledge of the nature of former attacks, of a ſimilar kind, where ſuch have occurred.

The experienced and accurate obſerver of the phenomena of diſeaſes, therefore, will ſeldom be at a loſs in ſelecting the proper mode of treatment in ſuch caſes: and it is fortunate here alſo, that the evacuation of blood-letting, which is abſolutely neceſſary to ſubdue a violent inflammatory affection of the bowels, often ſucceeds in removing a fixed and ſevere ſpaſm in the ſame organs. And as a ſpaſmodic affection, of conſiderable duration, is liable to terminate in inflammation and its fatal conſequences, the depletion of the blood-veſſels is indicated, under ſuch circumſtances, both as a preventive and as a cure, where the age, ſtrength, and conſtitution of the patient do not render the ſafety of ſuch a depletion very equivocal.

In regard to the treatment of inflammatory diſeaſes, we have already in part anticipated the diſcuſſion. The great deciſive remedy for ſuch diſeaſes is found, in diminiſhing the quantity of the circulating blood. This operation of blood-letting is ſuppoſed to produce its beneficial effects upon the diſeaſe, by removing the "ſtimulus of diſtention" from the blood-veſſels; for it is an aſcertained property of the living ſolid, to contract more forcibly after a great extenſion of its fibres. It cannot operate by letting out the *morbid matter* or *humour* from the circulating fluids, as the older pathologiſts imagined; for if we ſuppoſe the whole maſs of fluids to be impregnated with a morbid humour, how can we, by abſtracting a part, purify the condition of the remainder? The fact, however, is fully eſtabliſhed, and cannot be invalidated by any error in the hypotheſis, which may be framed for the purpoſe of explaining it. The depletion of the veſſels may be effected by opening the ſmaller branches of the arteries, where they are ſuperficial, and eaſily ſubjected to preſſure, as in the temples; or by opening the external veins by the lancet; or by a more limited and topical diſcharge by means of leeches, and cupping. The circumſtances, under which one or other of theſe modes of depletion is to be preferred, vary materially according to the ſeat and degree of inflammation, and will be mentioned under the head of each diſeaſe. While this mode of reducing inflammatory action is reſorted to, it is generally neceſſary, alſo, to employ other concurring means; ſuch as purging, exciting a diaphoreſis or gentle perſpiration, procuring a diſcharge from the ſkin in the vicinity of the inflamed organ, by bliſters, &c.; and, at the ſame time, to employ all the negative means of diminiſhing excitement, which conſtitute the antiphlogiſtic regimen; ſuch as avoiding heat, noiſe, exertion of body or mind, and ſhunning all ſolid animal food, condiments, ſpirituous, vinous, or other fermented liquors, which increaſe the action of the vaſcular ſyſtem.

INFLATION, formed from *in*, and *flatus*; of *flo*, *I blow*; *blowing up*, the act of ſtretching or filling any flaccid or diſtenſible body, with a flatulent or windy ſubſtance.

INFLECTION, called alſo *diffraction*, and *deflection*, in *Optics*, is a property of light, by reaſon of which, when it comes within a certain diſtance of any body, it will either be bent from it, or towards it; which is a kind of imperfect reflection or refraction. See Diffraction.

This property was firſt taken notice of by Dr. Hooke; who ſhews that it differs both from *reflection* and *refraction;* and ſeems to depend on the unequal denſity of the conſtituent parts of the ray, whereby the light is diſperſed from the place of condenſation, and rarified or gradually diverged into a quadrant: and this deflection, he ſays, is made towards the ſuperficies of the opaque body perpendicularly. Some writers aſcribe the firſt diſcovery of it to Grimaldi, the Jeſuit. He firſt publiſhed an account of it, in his treatiſe "De Lumine, Coloribus, et Iride," printed in 1666; nor did any other perſon lay claim to the diſcovery, except Dr. Hooke, who communicated his obſervations on this ſubject to the Royal Society, in 1672. It appears, however, that Dr. Hooke had not heard of the diſcoveries of Grimaldi; for he ſpeaks of his own as a diſcovery of a new property of light, not mentioned by any optical writer before him.

Sir Iſaac Newton diſcovered alſo, by plain experiment, this inflection of the rays of light; and M. de la Hire aſſures us he found, that the beams of the ſtars being obſerved, in a deep valley, to paſs near the brow of a hill, are always more refracted than if there were no ſuch hill, or the obſervations were made on the top thereof; as if the rays of light were bent down into a curve, by paſſing near the ſurface of the mountain.

Sir Iſaac Newton, in his Optics, makes ſeveral experiments and obſervations on the inflection of the rays of light; which ſee under Light, and Rays.

Although ſir I. Newton particularly examined the phenomena, relating to this ſubject, under a conſiderable variety of circumſtances, his obſervations were not quite correct; nor was his hypothetical explanation very plauſible. Subſequent experiments and obſervations ſeem to reduce the phenomena of inflection to a ſingle principle, *viz.* to the attraction of bodies towards light; which attraction becomes conſpicuous when the rays of light paſs within a certain diſtance of their ſurfaces. Beſides their being bent, the rays of light are likewiſe ſeparated into colours by the vicinity of bodies, and this produces the ſingular phenomenon of the coloured fringes that accompany the inflection. Various experiments have been made relative to the inflection of light by Maraldi, Grimaldi, Deliſle, Mairan, Du Tour, Muſchenbroek, and others, as well as Newton; an account of which experiments the reader may ſee in Prieſtley's Hiſtory of Viſion, Light, and Colours, part vi. § 6.

M. de la Hire obſerved, that when we look at a candle, or any luminous body, with our eyes nearly ſhut, rays of light are extended from it, in ſeveral directions, to a conſiderable diſtance, like the tails of comets. The true occaſion of this phenomenon, which has exerciſed the ſagacity of Des Cartes, Rohault, and others, ſeems to be, that the light paſſing among the eye-laſhes, in this ſituation of the eye, is inflected by its near approach to them, and therefore enters the eye in a great variety of directions.

Inflection, in *Grammar*, the variation of nouns and verbs, in their ſeveral caſes, tenſes, and declenſions.

Inflection is a general name, under which are comprehended both conjugation and declenſion.

Inflection, *Point of*, of a curve, in *Geometry*, is a point or place where the curve begins to bend, or turn a contrary way.

If a curve line, as A F K (*Plate* X. *Analyſis*, *fig.* 2.) be partly concave, and partly convex towards a right line, as A B, or towards a fixed point, the point F, which divides the concave from the convex part, and conſequently is at the beginning of the one and end of the other, is called the *point of inflection*, as long as the curve, being continued beyond F, keeps its courſe the ſame: when it returns back again towards that part or ſide from whence it took its origin, it is called the *point of retrogreſſion*.

To conceive this, it is to be conſidered, that any quantity, which goes on continually increaſing or decreaſing, cannot change from a poſitive to a negative expreſſion, or from a negative to a poſitive one, without firſt becoming equal to an infinite, or nothing. It becomes equal to nothing, if it continually decreaſe; and equal to an infinite if it continually increaſe.

Now, if through the point F be drawn the ordinate E F, and the tangent F L, and from any point, as M, on the ſame ſide of A F, be drawn the ordinate M P, and the tangent M T; then in curves which have a point of inflection, the abſciſs A P continually increaſes, and the part A T of the diameter, intercepted between the vertex of the diameter, and the tangent M T, increaſes alſo, till the point P fall into E; after which it again begins to diminiſh: whence the line A T muſt become a maximum A L, when the point P falls into the point E.

In thoſe curves which have a point of retrogreſſion, the part A T increaſes continually, and the abſciſs increaſes, till the point T falls into L; after which it again diminiſhes: whence A P muſt become a maximum, when the point T falls into L.

If A E $= x$, E F $= y$, then will A L $= \frac{y\,\dot{x}}{\dot{y}} - x$ (ſee Tangent), whoſe fluxion, which is $\frac{y^2\,\dot{x} - \ddot{y}\,\dot{x}\,y}{\dot{y}^2} - \dot{x} = \frac{\dot{y}^2\,\dot{x} - \ddot{y}\,\dot{x}\,y - \dot{y}^2\,\dot{x}}{\dot{y}^2} = -\frac{\ddot{y}\,\dot{x}\,y}{y^2}$, ſuppoſing $\dot{x}$ conſtant, being divided by $\dot{x}$, the fluxion of A L muſt become nothing; *i. e.* $\frac{-\ddot{y}\,y}{\dot{y}^2} = 0$: ſo that multiplying by $\dot{y}^2$, and dividing by $-y$, $\ddot{y} = 0$; which is a general form for finding F, the point of inflection, or retrogreſſion, in thoſe curves whoſe ordinates are parallel to one another. For the nature of the curve A F K being given, put the equation of the curve into fluxions; from which, or from other properties of the curve, find the value of $\dot{x}$ or $\dot{y}$, and put this $\dot{x}$ or $\dot{y}$ and its value into fluxions, making both $\dot{x}$ and $\ddot{y} = 0$: then by expunging the reſt of the fluxional quantities, we ſhall determine the value of x, *i. e.* A E or y, *i. e.* E F, at the point of inflection ſought.

To diſtinguiſh the points of inflection from thoſe of retrogreſſion, which ariſe indiſcriminately according to the above method, it will be ſufficient to attend to the progreſs of the curve, by taking any ordinate very near the point; which will always ſerve to remove any doubt on that head.

Ex. 1.—To find the point of inflection B in the curve A B Y (*fig.* 3.) whoſe equation (putting the abſciſs A C $= x$, ordinate C B $= y$, and the perpendicular A E $= a$) is $a\,x^2 = a^2\,y + x^2\,y$. From the fluxion of this equation, *viz.* $2\,a\,x\,\dot{x} = a^2\,\dot{y} + 2\,x\,\dot{x}\,y + x^2\,\dot{y}$, we deduce $\dot{y} = \frac{2\,a\,x\,\dot{x} - 2\,x\,\dot{x}\,y}{a^2 + x^2}$ *i. e.* by ſubſtituting for y its value $\frac{a\,x^2}{a^2 + x^2}$, $\dot{y} = \frac{2\,a^3\,x\,\dot{x}}{(a^2 + x^2)^2}$; and the fluxion of this equation, making both $\dot{x}$ and $\ddot{y} = 0$, is $0 = \frac{2\,a^3\,\dot{x}^2\,(a^2 + x^2)^2 - (4\,a^2\,x\,\dot{x} + 4\,x^3\,\dot{x})\,2\,a^3\,x\,\dot{x}}{(a^2 + x^2)^4}$, which multiplied by $(a^2 + x^2)^4$ and divided by $2a^3\dot{x}^2$, gives $0 = (a^2 + x^2)^2 - 4a^2x^2 - 4x^4$; therefore, $4x^4 + 4a^2x^2 = (a^2 + x^2)^2$; which equation divided by $x^2 + a^2$ makes $4x^2 = a^2 + x^2$; therefore $3x^2 = a^2$, and $x = a\sqrt{\tfrac{1}{3}}$; and if this value be ſubſtituted for it in the given equation of the curve, we ſhall have y, or the ordinate at the point of inflection $= \frac{ax^2}{a^2 + x^2} = \frac{\frac{1}{3}a^3}{\frac{4}{3}a^2} = \frac{1}{4}a$. Let A C be equal to $\frac{1}{3}$ A E, and with the radius c E, deſcribe the arc E C; then will C be the point from which the ordinate to the point of inflection muſt be drawn: for $e\mathrm{C} = \frac{2}{3}a$; and $\mathrm{C}e^2 - e\mathrm{A}^2 = \mathrm{AC}^2$, *i. e.* $\frac{4}{9}a^2 - \frac{1}{9}a^2 = \frac{1}{3}a^2 = \mathrm{AC}^2 = x^2$; or $x = a\sqrt{\tfrac{1}{3}}$.

Another method of finding the point of inflection, or retrogreſſion, is as follows. From the nature of curvature it is evident, that while a curve is concave towards its axis, the fluxion of the ordinate decreaſes, or is in a decreaſing ratio, with regard to the fluxion of the abſciſs; and on the contrary, this fluxion increaſes, or is in an increaſing ratio to the fluxion of the abſciſs, when the curve is convex towards the axis; and hence it follows, that theſe two fluxions are in a conſtant ratio at the point of inflection, or retrogreſſion, where the curve is neither concave nor convex; that is, $\frac{\dot{x}}{\dot{y}}$, or $\frac{\dot{y}}{\dot{x}}$, is a conſtant quantity. But conſtant quantities have no fluxion, or their fluxion is equal to 0; whence we derive this general rule.

Put the given equation of the curve into fluxions; from which equation of the fluxions, find either $\frac{\dot{x}}{\dot{y}}$, or $\frac{\dot{y}}{\dot{x}}$, and take again the fluxion of this fraction, and make it equal to 0, and from this laſt equation find alſo the value of the ſame expreſſion $\frac{\dot{x}}{\dot{y}}$, or $\frac{\dot{y}}{\dot{x}}$; and by equating theſe two, and the given equation of the curve, x and y will be determined, being the abſciſs or ordinate anſwering to the point of inflection. Or, otherwiſe, putting the fluxion of $\frac{\dot{x}}{\dot{y}} = 0$, that is $\frac{\ddot{x}\dot{y} - \ddot{y}\dot{x}}{\dot{y}^2} = 0$; or $\ddot{x}\dot{y} - \ddot{y}\dot{x} = 0$, whence $\ddot{x}\dot{y} = \ddot{y}\dot{x}$, or, $\dot{x} : \dot{y} :: \ddot{x} : \ddot{y}$, that is, the ſecond fluxions have the ſame ratio as the firſt fluxions; and therefore if $\dot{x}$ be conſtant, or $\ddot{x} = 0$, then ſhall $\ddot{y} = 0$, which gives the following rule, *viz.*

Take both the firſt and ſecond fluxions of the given equation of the curve; in which make $\ddot{x} = 0$, and $\ddot{y} = 0$, and the reſulting equations will determine the values of x and y, or the abſciſs and ordinate anſwering to the required point.

Thus repeating again the preceding example, in which the given equation is $ax^2 = a^2y + x^2y$; and of which the point of inflection is required.

By the firſt rule, the fluxion of $ax^2 = a^2y + x^2y$, is $2ax\dot{x} = a^2\dot{y} + 2xy\dot{x} + x^2\dot{y}$; whence $\frac{\dot{x}}{\dot{y}} = \frac{a^2 + x^2}{2ax - 2xy}$.

And now making again the fluxion of this quantity $= 0$, we have

$$2x\dot{x}(ax - xy) = (a^2 + x^2)(a\dot{x} - y\dot{x} - x\dot{y});$$

whence
$$\frac{\dot{x}}{\dot{y}} = \frac{a^2 + x^2}{a^2 - x^2} \times \frac{x}{a - y}.$$

And now equating theſe two expreſſions, we have

$$\frac{a^2 + x^2}{a^2 - x^2} \times \frac{x}{a - y} = \frac{a^2 + x^2}{2x} \times \frac{1}{a - y},$$

which being reduced, gives $2x^2 = a^2 - x^2$, or $3x^2 = a^2$, and $x = a\sqrt{\tfrac{1}{3}}$, the ſame reſult as before; and this value of x ſubſtituted in the original equation of the curve, becomes

$$y = \frac{ax^2}{a^2 + x^2} = \frac{\frac{1}{3}a^3}{\frac{4}{3}a^2} = \frac{1}{4}a,$$ the ordinate at the point of inflection.

The ſecond method differs from the firſt rather in enunciation than in principle, the application of it is therefore omitted.

Ex. 2.—Again, let it be propoſed to find the point of inflection in a curve whoſe equation is $by^2 = ax^2 - x^3$.

The fluxion of this expreſſion gives

$$b^2\dot{y} = 2ax\dot{x} - 3x^2\dot{x}; \text{ or } \frac{\dot{y}}{\dot{x}} = \frac{2ax - 3x^2}{b^2}.$$

Taking again the fluxion of this expreſſion, and making it equal to 0, we have

$$2ab^2\dot{x} - 6b^2x\dot{x} = 0, \text{ or } 2ab^2 = 6b^2x,$$

becauſe $\dot{y}$ does not enter; whence $x = \frac{1}{3}a$, which is the abſciſs anſwering to the point of inflection ſought.

Ex. 3.—Let it be propoſed to find the point of inflection, or retrogreſſion, in the cubic parabola, with the equation $y = a + \sqrt[3]{(a^3 - 2a^2x + ax^2)}$.

By taking the fluxion, we have

$$\dot{y} = \frac{(-2a^2 + 2ax)\dot{x}}{3(a^3 - 2a^2x + ax^2)^{\frac{2}{3}}}, \text{ or } \frac{\dot{y}}{\dot{x}} = \frac{\frac{2}{3}(ax - 2a^2)}{(a^3 - 2a^2x + ax^2)^{\frac{2}{3}}}.$$

Taking again the fluxion of this expreſſion, and making it equal to 0, according to the above rule, we have $a\dot{x}$

$$(a^3 - 2a^2x + ax^2)^{\frac{2}{3}} = \frac{2(-2a^2\dot{x} + 2ax\dot{x}) \times (2ax - 2a^2)}{3(a^3 - 2a^2x + ax^2)^{\frac{1}{3}}}$$

becauſe $\dot{y}$ is not found in the ſecond fluxion, which expreſſion being reduced, gives $x = a$; and this value ſubſtituted for x, gives alſo $y = a$; hence the point required is, that anſwering to theſe conditions of the abſciſs and ordinate, which is a point of retrogreſſion, as will appear from conſidering the nature of the curve.

Ex. 4.—Let it be propoſed to inveſtigate the point of contrary flexure in the curve commonly called the *witch*; of which the equation is $y^2x = a^3 - a^2x$.

Taking the fluxion of this expreſſion, we have

$$2y\dot{y}x + y^2\dot{x} = -a^2\dot{x}; \text{ or } \frac{\dot{y}}{\dot{x}} = \frac{-(a^2 + y^2)}{2yx}.$$

Now, again, making the fluxion of this expreſſion $= 0$, we have

$$-4y^2\dot{y}x + (2x\dot{y} + 2y\dot{x})(a^2 + y^2) = 0, \text{ or}$$
$$2x(a^2 + y^2)\dot{y} - 4y^2x\dot{y} + 2y\dot{x}(a^2 + y^2) = 0;$$

whence

$$\frac{\dot{y}}{\dot{x}} = \frac{-2y(a^2 + y^2)}{2x(a^2 + y^2) - 4y^2x}.$$

And now equating this value of $\frac{\dot{y}}{\dot{x}}$ with the foregoing, there is obtained

$$\frac{2y(a^2+y^2)}{2x(a^2+y^2)-4y^2x}=\frac{a^2+y^2}{2yx}$$

or, $4y^2x = 2x(a^2+y^2) - 4y^2x$, or $4y^2 = a^2+y^2$; whence $y = a\sqrt{\tfrac{1}{3}}$; which being ſubſtituted in the original equation, gives $x = \tfrac{3}{4}a$; which are therefore the values of x and y anſwering to the required point of inflection.

At preſent we have only conſidered thoſe curves that have parallel ordinates, and which are referred to one common axis; but it is neceſſary to employ a different method when the curves are referred to a common focus; it will therefore be proper now to attend to this latter caſe, obſerving only, with regard to the former, that in order to know whether any curve be concave or convex towards any point aſſigned in the axis, find the value of $\ddot{y}$ at that point; then if this value be poſitive, that curve will be convex towards the axis, and if it be negative, it will be concave. The rule for determining the points of contrary flexure and retrogreſſion of curves, which ſuppoſes the ſecond fluxion of the ordinate to be nothing or infinite, *i. e.* $\ddot{y} = 0$ or ∞, is liable to ſeveral exceptions, as is ſhewn very fully and clearly by Maclaurin in his Treatiſe of Fluxions, book i. chap. 9. book ii. chap. 5. art. 866 and 867.

The ordinate y paſſes through a point of contrary flexure when, the curve being continued on both ſides of the ordinate, $\dot{y}$ is a maximum or minimum. But this does not always happen when $\ddot{y} = 0$, or ∞. Maclaurin obſerves, in general, that if $\ddot{y}$, $\dddot{y}$, $\ddddot{y}$, &c. vaniſh, the number of theſe fluxions being odd, and the fluxions of the next order to them having a real and finite value, then y paſſes through a point of contrary flexure; but if the number of theſe fluxions that vaniſh be even, it cannot be ſaid to paſs through ſuch a point; unleſs it ſhould be allowed that a double infinitely ſmall flexure can be formed at one point.

The curve being ſuppoſed to be continued from the ordinate y, on both ſides, if $\ddot{y}$ be infinite, the extremity of the ordinate is not therefore always a point of contrary flexure, as $\dot{y}$ is not always, in this caſe, a maximum or minimum; and the curve may have its concavity turned the ſame way on both ſides of the ordinate. But theſe caſes may be diſtinguiſhed by comparing the ſigns of $\ddot{y}$ on the different ſides of the ordinate; for when theſe ſigns are different, the extremity of y meeting the curve is a point of contrary flexure.

The ſuppoſitions of $\dot{y} = 0$, or ∞, and of $\ddot{y} = 0$, or ∞, ſerve to direct us where we are to ſearch for the maxima and minima, and for points of contrary flexure; but we are not always ſure of finding them. For though an ordinate or fluxion that is poſitive, never becomes negative at once, but by increaſing and decreaſing gradually, yet after it has decreaſed till it vaniſh, it may thereafter increaſe, continuing ſtill poſitive; or after increaſing till it becomes infinite, it may thereafter decreaſe without changing its ſign.

Of the points of inflection and retrogreſſion of curves referred to a common focus.

Let A D E (*figs.* 4. and 5.) repreſent a curve referred to the focus Q, from whence the ordinates Q D, Q D proceed; and let Q d be indefinitely near to Q D. Draw Q T perpendicular to Q D, and Q t perpendicular to Qd. Draw D T a tangent to the point D, and d t a tangent in the point d. Let Q t (produced if neceſſary) meet D T in the point o. Now it is plain, that as the ordinates increaſe, if the curve be concave towards the focus Q (*fig.* 4.), Q t will be greater than Q T; but if the curve be convex towards the focus Q (*fig.* 5.) Q t will be leſs than Q T; and therefore, as the curve changes from being concave to convex, or *vice verſâ*, that is, in the point of inflection, or retrogreſſion, the line or quantity $o\,t$, from being poſitive, ought to become negative, or the contrary; and therefore muſt paſs through nothing or infinity.

Therefore make Q D = y, D M = $\dot{x}$, and with the centre Q, let the indefinitely ſmall arcs D M, T H, be deſcribed: then the two triangles d M D, d Q T will be ſimilar, as alſo d Q o, T H o, and therefore it will be d M : M D :: d Q (or D Q) : Q T, or $\dot{y} : \dot{x} :: y : \frac{\dot{x}y}{\dot{y}} =$ Q T. But the two ſectors D Q M, T Q H are alſo ſimilar; whence D Q : D M :: Q T : T H, or $y : \dot{x} :: \frac{y\dot{x}}{\dot{y}} : \frac{\dot{x}\dot{x}}{\dot{y}} =$ T H; and becauſe of the ſimilar triangles d Q o, and T H o, it will be d Q (or D Q) : Q o (or Q T) :: T H : H o; that is, $y : \frac{y\dot{x}}{\dot{y}} :: \frac{\dot{x}^2}{\dot{y}} : \frac{\dot{x}^3}{\dot{y}^2} =$ H o. But H t (*fig.* 3.) repreſents the fluxion of Q T, that is, H $t = \frac{\dot{x}\dot{y}^2 - y\dot{x}\ddot{y}}{\dot{y}^2}$ by taking $\dot{x}$ as conſtant. Therefore $t\,o = t$ H + H $o = \frac{\dot{x}\dot{y}^2 - y\dot{x}\ddot{y} + \dot{x}^3}{\dot{y}^2}$, which muſt be equal to 0, or to ∞, infinity; and conſequently multiplying by $\dot{y}^2$, and dividing by $\dot{x}$, it will be $\dot{y}^2 - y\ddot{y} + \dot{x}^2 = 0$, or ∞.

In *fig.* 4. $o\,t$ becomes negative, and therefore $o\,t = \frac{-\dot{x}\dot{y}^2 + y\dot{x}\ddot{y} - \dot{x}^3}{\dot{y}^2}$, and multiplying and dividing this expreſſion as above, we have again

$$\dot{y}^2 - y\ddot{y} + \dot{x}^2 = 0, \text{ or } \infty,$$

which therefore is the general formula for finding the point of inflection or retrogreſſion in curves that are referred to a focus.

Let us now make an application of this formula to an example, by propoſing to find the point of contrary flexure in the curve, which is generated as follows:

A E D being a circle deſcribed from the centre B, let A F K be ſuch a curve, that, drawing any radius B F E, the ſquare of F E may be always equal to the rectangle of the correſponding arc A E, into a right line b. See *fig.* 6.

Let the arc A E = z, B A = B E = a, B F = y, and F G = $\dot{x}$, drawing B E′ indefinitely near to B E, and with the centre B, and radius B F deſcribe the ſmall arc F G; then by the nature of the curve, it will be $bz = a^2 - 2ay + y^2$; and taking the fluxions we have $b\dot{z} = -2a\dot{y} + 2y\dot{y}$, whence $\dot{z} = \frac{2y\dot{y} - 2a\dot{y}}{b} =$ B E′. But becauſe of the ſimilar ſectors B E E′, and B F G, it will be as B E : B F :: E E′ : F G; that is, $a : y :: \frac{2y\dot{y} - 2a\dot{y}}{b} : \dot{x}$; whence $\dot{x} = \frac{2y^2\dot{y} - 2ay\dot{y}}{ab}$; and now taking the fluxions again and making $\dot{x}$ conſtant, we have $4y\dot{y}^2 + 2y^2\ddot{y} - 2a\dot{y}^2 - 2ay\ddot{y} = 0$; therefore $y\ddot{y} = \frac{a\dot{y}^2 - 2y\dot{y}^2}{y - a}$.

Now the general formula above is $\dot{x}^2 + \dot{y}^2 - y\ddot{y} = 0$, and therefore ſubſtituting for theſe quantities their reſpective values, the expreſſion becomes

$$\frac{4 y^{4} \dot{y}^{2} - 8 a y^{3} \dot{y}^{2} + 4 a^{2} y^{2} \dot{y}^{2} + a^{2} b^{2} \dot{y}^{2}}{a^{2} b^{2}} -$$

$$\frac{a \dot{y}^{2} - 2 y \dot{y}^{2}}{y - a} = 0,$$ and theſe again reduced to a common denominator will be

$$\frac{4 y^{5} - 12 a y^{4} + 12 a^{2} y^{3} - 4 a^{3} y^{2} + 3 a^{2} b^{2} y - 2 a^{3} b^{2}}{a^{2} b^{2} (y - a)}$$

$= 0$, or ∞; the roots of which equations will give thoſe values of y, or of B F, that anſwer to ſo many different points of contrary flexure. In general the number of roots in the finite equation always indicate the number of points of inflection or retrogreſſion belonging to the curve which is the ſubject of inveſtigation; and conſequently, in thoſe curves that have but one ſuch point, it is determined by a ſimple equation.

Curves may alſo have another kind of retrogreſſion different from that we have been conſidering; which is, when the curve returns backwards towards its origin, turning its cavity the ſame way that it did before its retrogreſſion, as in the following caſe.

Let the curve be B A C (*fig.* 7.), with a contrary flexure at A, and let it be evolved by a thread beginning at any point D, different from the point of contrary flexure A: the evolution of the portion D C generates the curve D G, and that of the portion A B generates the curve E F; in ſuch manner that the evolution of the whole curve B A C will form the entire curve F E D G, which has two retrogreſſions, one at D of the uſual form, becauſe the two branches D E, D G, turn their convexity; the other at E of the ſecond ſort, becauſe the branches E D, E F, are concave towards the ſame parts. Let now m N, N n m, be any two radii, indefinitely near, of the evolute D A; and N H, and n H, two perpendiculars to the ſame; the two indefinitely ſmall ſectors N m M, H N n, will be ſimilar, and therefore H N : N M :: N n : M m. But in the point of contrary flexure A, the radius H N ought to be either infinite, or nothing; and the radius N m, which becomes A E, continues finite. Therefore, in the caſe of contrary flexure A, that is, the point of retrogreſſion E, of the ſecond ſort, the ratio of N n, M m, or the ratio of the fluxion of the radius M N, to the element of the curve, ought to be either infinitely great, or infinitely ſmall. But the formula of the radius M N is $\frac{(\dot{x}^{2} + \dot{y}^{2})^{\frac{3}{2}}}{- \dot{x} \ddot{y}}$, conſidering $\dot{x}$ as conſtant; the fluxion of which is

$$\frac{- 3 \dot{x} \dot{y} \ddot{y}^{2} \sqrt{(\dot{x}^{2} + \dot{y}^{2})} + \dot{x} \dddot{y} (\dot{x}^{2} + \dot{y}^{2})^{\frac{3}{2}}}{\dot{x}^{2} \ddot{y}^{2}}$$

and M $m = \sqrt{(\dot{x}^{2} + \dot{y}^{2})}$; therefore $\frac{\text{N } n}{\text{M } m} =$

$$\frac{\dot{x}^{2} \dddot{y} + \dot{y}^{2} \dddot{y} - 3 \dot{y} \ddot{y}^{2}}{\dot{x} \ddot{y}^{2}} = 0, \text{ or } \infty;$$

which is the formula for points of retrogreſſion of the ſecond order.

For other methods of finding the points of inflection and retrogreſſion of curves, the reader is referred to Simpſon's and Maclaurin's Fluxions; Donna Agneſi's Analytical Inſtitutes; and to the Traité Elementaire de Calcul Differentiel, par La Croix.

INFLORESCENCE, in *Botanical Phraſeology*, *infloreſcentia* of Linnæus, is uſed to expreſs the particular manner in which flowers are diſpoſed upon a plant, and which preceding writers denominated the *modus florendi*, or "manner of flowering." The ſeveral kinds of infloreſcence come under the heads of *Verticillus*, *Racemus*, *Spica*, *Corymbus*, *Faſciculus*, *Capitulum*, *Umbella*, *Cyma*, *Panicula* and *Thyrſus*, which the reader will find in their proper places. A ſlight correction of the definition which ſtands under our article CAPITULUM is neceſſary, the *Statice Armeria* or Thrift, and *Gomphrena globoſa* or Globe amaranthus, being better examples of that kind of infloreſcence than any compound flower.

For the reaſons againſt taking generic characters from the infloreſcence, ſee CYME and GENUS.

INFLUENCE, a quality ſuppoſed to flow from the bodies of the ſtars, either with their heat or light, to which aſtrologers vainly attribute all the events which happen on the earth.

Alchemiſts, alſo, who to this aſcribe the philoſopher's ſtone, tell us that every thing in nature is produced by the influences of the ſtars, which, in their paſſage through the atmoſphere, imbibe many of its moiſt parts, the groſſeſt whereof they depoſit in the ſands and earths where they fall; that theſe, filtrating through the pores of the earth, deſcend even to the centre, whence they are driven, by the central fire, back again to the ſurface; and in their aſcent, by a natural kind of ſublimation, as they find earths duly diſpoſed, they form natural bodies, as metals, minerals and vegetables, &c. Thus it is pretended, that chemiſtry, conſiſting of an artificial imitation of theſe natural operations, and in applying active principles to paſſive principles, can form natural bodies, make gold, &c. See TRANSMUTATION, and PHILOSOPHER'S STONE.

INFLUENT, a term uſed where a liquor or juice, by the contrivance of nature, and the laws of circulation, falls into a current or receptacle.

Thus with reſpect to the common receptacle, the chyle is its influent juice; and ſo is the bile to the gall-bladder; the venal blood to the heart in its diaſtole; and the like.

INFLUENZA, in *Medicine*, a term generally employed to denote an *epidemic catarrh*, which has at different times ſpread more rapidly and extenſively than any other epidemic diſorder. For it has ſeldom occurred in any one country of Europe without appearing ſucceſſively in every other part of it; it has ſometimes apparently traverſed the whole of the old world; and, in ſome inſtances, it has been even transferred to America, and has ſpread itſelf over that continent likewiſe. The French give it the name of *La Grippe*.

In truth, this extenſive prevalence of the diſeaſe conſtitutes its moſt remarkable peculiarity: for in all the inſtances of its occurrence, from the fourteenth century down to the preſent day, its phenomena have not only been pretty uniformly the ſame, but have differed little, except in ſeverity, from thoſe of the common febrile catarrh. (See CATARRH.) This will appear from the following deſcription of the diſeaſe, when epidemic in 1782, which is taken from a comprehenſive view of it, compiled by the late Dr. Gray, of the Britiſh Muſeum, from a number of accounts given by phyſicians, in various parts of Great Britain, from their own perſonal obſervation (ſee Medical Communications, vol. i. art. 1. Lond. 1784); and from a ſimilar account publiſhed by the College of Phyſicians. Med. Tranſactions, vol. iii. art. 8.

Very little authentic information was procured reſpecting the hiſtory of this epidemic, before the time of its appearance in London: all that was ſtated, on good authority, was, that it prevailed at Moſcow in the months of December 1781, and January 1782, and at Peterſburgh in February 1782; and it was traced to Tobolſki, to which place it was ſuppoſed to have been brought from China. In confirmation of this opinion it was obſerved, that ſeveral accounts from different parts of the Eaſt Indies made mention of a diſorder, ſimilar in its ſymptoms, which prevailed in thoſe parts in the months of October and November 1781. At all events, its courſe was in the beginning weſtward; for it was in Denmark in the latter end of April 1782, or the beginning of May; and many people were ſaid to have died of it at Copenhagen before the 11th of May. It appeared at Newcaſtle-upon-Tyne about the end of April, and in the ſecond week in May it was certainly in London; ſome perſons indeed thought that it had reached the metropolis ſooner. According to the accounts received from various parts of England, it did not begin to appear in moſt of them until after its prevalence in London, namely, until the latter end of May, or the beginning of June. In Scotland and Ireland it ſeems to have been rather later, and in the ſouth of Europe later ſtill; for it prevailed in France in the months of June and July; in Italy, in July and Auguſt; and in Portugal and Spain, in Auguſt and September. The fourth week in May was the period of its moſt general prevalence in London: from that time it began to decline, and in the ſpace of two or three weeks ceaſed to exiſt as a general diſorder; but it did not altogether leave the city till the month of September.

No attempt was made to aſcertain with accuracy the proportional number of perſons attacked by this influenza: the number was every where very great; the proportion of the inhabitants affected in ſome places being eſtimated at three-fourths, in other places at four-fifths of the whole: and in London it was aſſerted, from a pretty competent view of the matter, that the number of thoſe attacked by it was much greater than that of thoſe who eſcaped it. Both ſexes appeared to be equally liable to it; but perſons of the middle age were more ſubject to its attacks than old people, and theſe more than children; while infants were conſiderably leſs pre-diſpoſed to it than either, though not entirely exempt from it. When old perſons were attacked, they generally had the diſeaſe very violently.

This epidemic appeared with a conſiderable variety of ſymptoms; but the moſt general form of it was certainly that of catarrh; and the great debility or depreſſion of ſtrength which accompanied its attack, and the rapidity with which its ſymptoms came on, (which in ſome inſtances was truly wonderful,) ſeem to have been the moſt remarkable characters of it. Perſons, apparently in perfect health, were ſeized inſtantaneouſly, as it were, with a violent cold, to which ſucceeded head-ache, running at the noſe, &c.; while others were as ſuddenly ſeized with giddineſs, ſtricture on the cheſt, ſickneſs at the ſtomach, and cold ſweats, which were ſpeedily followed by the pectoral ſymptoms. The moſt common courſe of the ſymptoms, however, was the following:

The diſeaſe generally began with ſits of chillineſs and heat alternately ſucceeding each other; ſometimes with a ſlight ſhivering, followed by more or leſs of fever; anxiety of the præcordia; pain in the back and limbs; ſtitches and cramps in the muſcles ſubſervient to reſpiration; a very great diſcharge of their lymph from the eyes and noſe; a ſenſation in the eyes as if they were about to ſtart out of the head; ſneezing, hoarſeneſs, and frequently an inceſſant cough, forcing up large quantities of mucus, and ſometimes attended with a ſoreneſs of the breaſt. In many inſtances the appetite and ſenſe of taſte were loſt or much impaired, with ſome degree of nauſea; and a few vomited. Moſt of the patients laboured under great laſſitude and reſtleſsneſs. The ſleep was generally much broken; and many could hardly ſleep at all. The pulſe was frequent, but ſeldom hard or tenſe. Languor, debility, and dejection of ſpirits were general, and very great in all; far beyond what might have been expected from the degree of all the other ſymptoms. But the ſymptom which univerſally prevailed, and which appeared to be almoſt a pathognomonic of the diſeaſe, was a diſtreſſing pain and ſenſe of conſtriction in the forehead, temples, and ſometimes in the whole face, accompanied with a ſenſe of ſoreneſs about the cheek-bones under the muſcles. This, now and then, was felt previouſly to the catarrh, and not unfrequently was followed by very little or no catarrhous affection.

The diſtemper was by no means ſo uniform as to preſent the ſame identical appearances in every ſubject whom it attacked; nor yet ſo various, but that the reſemblance could eaſily be diſcovered; diverſified perhaps by the peculiar habit and conſtitution of the ſufferer, or by ſome other circumſtances not eaſily explained. In ſome, a part only of the mucous membrane was affected, in others the whole. In the latter, a ſoreneſs of the throat was common, with frequent excretion. Upon inſpecting the *fauces* of theſe, a redneſs might be obſerved; but in few inſtances any conſiderable ſwelling, and in none any ulceration. In ſome there was a great propenſity to perſpiration; it could be readily excited in moſt, and often appeared where no means had been employed for that purpoſe; but in a few the ſkin was dry throughout the whole complaint. Daily exacerbations and remiſſions of the cough and fever were obvious in many inſtances; in ſome, they either did not take place, or if they did, were very obſcure. The ſtate of the belly was very different in different patients; in ſome it was regular, in others diſpoſed to coſtiveneſs; which, however, was eaſily removed: and ſeveral had a ſpontaneous purging at various periods of the diſeaſe, ſometimes with pain, but oftener without. Nothing in general could be collected from the urine that deſerves notice.

Theſe were the moſt general and frequent appearances of the influenza of 1782. But it muſt be obſerved, that not only in London, but in all parts of the iſland from whence accounts were received, it now and then degenerated into pleuriſy or peripneumony; yet theſe affections ſtill manifeſted themſelves as particular modifications of the epidemic, being either preceded or accompanied by ſome of its characteriſtic ſymptoms. Some, thus attacked, had in the beginning either that diſtinguiſhing pain in the face and forehead, or catarrh, or both: and in all there was that debility of body and depreſſion of mind, which are not eſſential to inflammation; the preſence of which here, however, was obvious and indiſputable.

The rarer occurrences were in ſome few an unuſual diſpoſition to ſleep; in others, ſtrangury independent of bliſters, and in ſome inſtances attended with bloody urine for three or four days; hæmorrhages from the noſe, with relief to the catarrhal affections; and one inſtance of a clear diſcharge from the ears, as copious as others had it from the noſe.

Extenſive as the range of this epidemic was, its influence was neither very fatally exerted, nor long continued. Very few died of it; and of thoſe to whom it proved fatal, the greater part were old, aſthmatic, or had been debilitated by ſome previous indiſpoſition. The continuance of the diſtemper in any one place was not above ſix weeks: where it appeared in May, it vaniſhed before the end of June; and where it did not break out before June, it remained until the middle, or towards the decline of July. Its duration with each individual whom it attacked was as various as the degree of violence with which the attack was made. It ſeldom held any one above a fortnight; in ſome its duration was not above a day or two; but it uſually laſted about a week, or longer. In ſome parts of the country relapſes were common a ſecond, third, or even fourth time; this was alſo the caſe in London, but to a leſs extent. The cough was ſometimes troubleſome for a conſiderable time after the febrile ſtate of the diſorder had ceaſed; and a great weakneſs often remained after the diſeaſe.

The influenza, as above deſcribed, may be taken as an example of the epidemic at all times of its appearance; but it has ſometimes aſſumed a more violent and inflammatory type, been more frequently accompanied with ſymptoms of pleuriſy and peripneumony, and therefore more frequently fatal, and alſo laid the foundation for more numerous caſes of pulmonary conſumption, than in the inſtance of 1782. Such was the fact, in regard to the influenza of 1762 in particular; which, indeed, appeared to be far more fatal, both at the time of its raging, and in its conſequences, as ſeveral perſons continued languiſhing under the remains of it for one or two years, and never recovered.

The cauſes of the influenza have been the ſubject of much difference of opinion; and all that has been ſaid in reſpect to them rather tends to prove the difficulty of obtaining a ſufficient number of unqueſtionable facts to found a clear opinion upon, than to ſet the ſubject at reſt. Three different views of the matter have been taken by different phyſicians: 1. Some attributed the diſeaſe ſolely to the ſtate of the weather; *i. e.* they believed it to be a common catarrh, occaſioned by changes in the ſenſible qualities of the atmoſphere, ſuch as cold, moiſture, &c.: 2. Others aſcribed it to a particular and ſpecific morbid principle, totally different from and independent of the ſenſible qualities of the atmoſphere, but reſident in and conveyed by the air: 3. While the greateſt number concurred in the opinion, that the influenza was contagious, in the ordinary acceptation of the word, *i. e.* was propagated only by the contact, or at leaſt by the ſufficiently near approach, of an infected perſon. The *firſt* opinion, however, that it originated in the ſenſible variations of the air, ſeems to be untenable: for not only was there no peculiarity of the atmoſpherical temperature, moiſture, &c., which was common to the different periods when the influenza prevailed, or was obviouſly different from that of other ſeaſons, when it had not appeared; but the ſenſible ſtate of the air preceding and accompanying the ſame epidemic was different in different places. Thus, though in moſt parts of England it had been uncommonly cold and wet, yet in the other parts of the world, as in Germany, where the diſorder was equally general, it had been very dry. Again, it was obſerved in ſeveral places, that great alterations happened in the weather during its prevalence, without any ſenſible change in the ſymptoms of the diſorder.

The *ſecond* opinion, that the cauſe of the diſeaſe, though not connected with the ſenſible qualities of the atmoſphere, was yet reſident in it, and thus conveyed from place to place, was ſupported upon the following grounds: 1ſt. That thoſe who were moſt expoſed to the air were generally the firſt perſons attacked: 2dly. That many had the diſorder without having had any communication with a diſeaſed perſon: 3dly. That ſeveral eſcaped though ſurrounded by perſons ill of the diſeaſe: 4thly. That ſome *whole families* were ſeized *at once*: and, 5thly. That ſome perſons had the diſorder a week or a fortnight before it began to be taken notice of as a general one. Without preſuming to decide upon ſo difficult and intricate a queſtion, we may ſtate the following objections to theſe arguments.

The firſt argument, that thoſe who were moſt expoſed to the air were generally the firſt perſons attacked, (which, by the way, was altogether denied by many obſervers,) is ſurely by no means in favour of the opinion, that the cauſe of the diſorder reſided in the atmoſphere; for if it had reſided there, what ſhould have prevented thoſe who ſtaid at home from being infected? ſince the air which they breathed muſt neceſſarily have been the ſame as that breathed by thoſe who went out. But if, on the other hand, a communication with ſome infected perſon was neceſſary to produce the diſtemper, it is very clear that thoſe who went out of doors, and mixed with the world, were more likely to get it than thoſe who did not ſtir from home.

Before the ſecond argument, namely, that many were attacked without having had any communication with a diſeaſed perſon, can be allowed to have any weight, it muſt be clearly proved, not only that the perſons themſelves had not had ſuch communication, but alſo, that no perſon, who had been near them, had previouſly been where the diſorder exiſted: for it is pretty clearly eſtabliſhed, with reſpect to other active contagions, ſuch as the ſmall-pox, &c. that a perſon, who has already ſuffered the diſeaſe, may nevertheleſs convey the contagion from one place to another.

From the third argument, that many eſcaped though ſurrounded by perſons affected with the diſeaſe, no inference of any conſequence to the preſent queſtion can be drawn; it being certainly not leſs difficult to account for their eſcape when ſurrounded by diſeaſed perſons, than when ſurrounded by the ſame air, which had (according to the hypotheſis) cauſed the diſeaſe in thoſe perſons.

With reſpect to the fourth argument, that ſome *whole families* were ſeized *at once*, without having been expoſed to infection, it may be remarked that, when we conſider what has been ſaid in anſwer to the ſecond argument, it will be very difficult to prove that they were not expoſed to it; and equally difficult to give any reaſons why, if the exciting cauſe of the diſorder reſided in the air, any whole family ſhould have been affected by that cauſe, rather than an equal number of perſons in divers families; but if we ſuppoſe the diſeaſe to have been propagated by perſonal intercourſe, it is very eaſy to conceive in what manner it may have been communicated to ſome whole families at the ſame time. And, in anſwer to the laſt argument, that ſome perſons had the diſorder a week or a fortnight before any others were known to have it, it may be ſufficient to remark, that, admitting theſe caſes to have been really influenza, the ſuppoſition, that the cauſe of it exiſted in the air, will not render it more eaſy to explain why thoſe perſons only ſhould at that time have been affected by this cauſe.

Theſe conſiderations tend to favour the *third* opinion above-mentioned, that the diſeaſe was propagated by contagion, in the common acceptation of the term, that is, by perſonal communication with the diſeaſed; but they are very far from being deciſive of the queſtion. Indeed, the queſtion of contagion, as connected with any particular epidemic, in which there is no palpable matter produced, by which the diſeaſe can be communicated, is always difficult, and has been agitated even with regard to the plague itſelf. (See CONTAGION and EPIDEMIC.) But it has been ſatisfactorily demonſtrated, that the contagion of all malignant and eruptive fevers cannot be conveyed through the air to any diſtance (even many feet) from its ſource. If the contagion of the influenza, therefore, could be ſuſpended and conveyed through the atmoſpheric air, ſo as to ſpread the diſeaſe far and wide, it would form an exception to the general properties of known contagions. Several facts, recorded during the epidemic of 1782, militate ſtrongly againſt ſuch a ſuppoſition. It was remarked, for example, that the diſeaſe was prevalent in one place a week or two before it appeared in another, only a few miles diſtant from the firſt. Thus it ſhewed itſelf at Edinburgh on the 20th of May, and ſoon raged very much, and was prevalent at Glaſgow in the firſt week in June; yet it did not appear at Muſſelburgh, a village about five miles ſouth-eaſt of Edinburgh, until the 9th or 10th of June. Again, it was prevalent at Dartmouth much ſooner than at Exeter, and yet it appeared at Exeter much ſooner than at Tinmouth, although the laſt mentioned place is ſituated between Dartmouth and Exeter.

The opinion, that it was propagated by perſonal intercourſe, was alſo favoured by its progreſs in numerous inſtances. Thus it was frequently obſerved, that ſome one individual in a family was firſt attacked, and that then ſeveral more, and ſometimes the whole of the ſame family, were very ſoon afterwards ſeized with it, in ſome inſtances all at once, but in others ſucceſſively. Very early in June, three families, conſiſting of ſeventeen perſons, came on the ſame day to the hotel in the Adelphi buildings; they were all in perfect health when they arrived; and they were all affected the next day with the ſymptoms of the illneſs then reigning in London. In ſome caſes, it ſeemed to be propagated, like contagious diſeaſes in general, by *fomites*, that is, by articles of clothing or furniture impregnated with the morbific effluvia. One phyſician, Dr. Meaſe of Strabane, in Ireland, ſays, "I have no ſhadow of doubt that the diſorder was contagious; and am certain, I myſelf received the infection from a ſmall trunk of wearing apparel, which came from Dublin, where it then raged. I may add, that this was the firſt introduction of it into this town." The diſeaſe appeared to be carried on board two ſhips of war, on their arrival at Graveſend from the Weſt Indies, by three cuſtom-houſe officers, who were put on board: in a few hours after, the crews of both ſhips, till then in good health, were ſeized with ſymptoms of the influenza; hardly a man in either ſhip eſcaped, and ſome had it very ſeverely. In ſome inſtances it was obſerved, that the epidemic did not ſhew itſelf in certain places, until ſome one or more arrived at thoſe places, either actually labouring under the diſeaſe, or coming immediately from other places, whoſe inhabitants had been affected by it for ſome days. In general the diſeaſe appeared earlier in towns, than it did in the ſurrounding villages, and in villages earlier than in the detached houſes in the neighbourhood.

On the whole, the progreſs of the diſorder is perhaps more eaſily explained, upon the ſuppoſition that it was propagated by perſonal communication, than by any other. In objection to this hypotheſis, however, it is credibly affirmed, that the crews of ſeveral ſhips were ſeized with the influenza many miles diſtant from land, and came into various ports of England labouring under it; and the ſame thing is ſaid to have happened to ſhips in the Eaſt Indies, and other parts. But great caution is requiſite in admitting ſuch ſtatements as facts, from which any ſatisfactory inferences can be deduced.

A ſimilar epidemic catarrh, or influenza, is recorded as having viſited Europe, and even other parts of the globe, two or three times in the fourteenth century, and at ſeveral ſubſequent periods; namely, in the year 1510, 1575, and 1580, the laſt of which is ſaid to have originated, like ſeveral of thoſe which ſucceeded, in Aſia; and again in 1591, in 1658, in 1675, in 1709, in the latter end of 1732, and in the beginning of 1733, in 1743, in 1748, in 1762, in 1767, in 1775, in 1782, and in 1803. Thoſe who are deſirous of inveſtigating the records of theſe epidemics, will find references to the works in which they are contained, arranged in chronological order, in Dr. Cullen's Synopſis Noſologiæ Method. under the head of Catarrhus, Gen. xl. and ſpecies 2. C. *à contagio.*

Cure of the Influenza.—Since the effects of this diſeaſe were different in different individuals, no general method of cure could rationally be followed. Many, indeed, were ſo ſlightly indiſpoſed, as to require but little or no medicine. Nothing more was wanted for their cure, than to abſtain for two or three days from animal food and fermented liquors, and to uſe ſome diluting tepid drink. A lenient purgative, given at the beginning of the diſeaſe, was uſeful in moderating the fever; and nature ſometimes ſeemed to point out the repetition of it afterwards, when there were pains in the ſtomach and bowels, and a tendency to a diarrhœa. The ſame was obſerved in the epidemics of 1732 and 1762. Nothing likewiſe was obſerved ſo ſucceſsfully to mitigate the cough, as to open the bowels with a gentle purgative, and afterwards to give a ſlight opiate at night. It was obſerved by numerous practitioners, that emetics, exhibited upon the firſt attack, were evidently of uſe in relieving the head and breaſt, and alſo in producing a ſpeedy and free perſpiration. All attempts to force much ſweating appeared to do harm, eſpecially by means of the ſtimulating diaphoretics, ſuch as contrayerva, ammonia, wine whey, &c. In fact, in moſt of the mild and ſimpler forms of the diſeaſe, an early perſpiration generally came on ſpontaneouſly, which ſeldom failed to relieve the ſymptoms materially, and it was only neceſſary to give tepid aqueous liquors, the neutral ſalts, or antimonials in ſmall doſes, to keep up a regular and gentle moiſture upon the ſkin.

But in the more ſevere forms of the diſorder, other remedies became neceſſary, according to the ſeverity of the ſymptoms. Whenever ſymptoms of pleuriſy or peripneumony appeared, the propriety of blood-letting was commonly admitted, notwithſtanding the languor and depreſſion connected with the diſeaſe. There was, however, conſiderable difference of opinion upon the ſubject of blood-letting. Several learned and experienced phyſicians, if called at the beginning of the diſeaſe to a perſon ſtrong and plethoric, and labouring under great heat and inquietude, even in caſes where no direct ſymptoms of pneumonic inflammation appeared, ordered bleeding without heſitation; and under ſuch circumſtances, they ſeveral times obſerved, that the languor, oppreſſion, and feveriſh anxiety, were abated by the loſs of a few ounces of blood; that both the head and the breaſt were relieved; and that the diſeaſe proceeded to its termination with fewer difficulties both to the patients and to themſelves, and without any ſubſequent inconvenience. Yet others were of opinion that the blood-letting, although indicated by the ſymptoms, and alſo by the appearance of the blood drawn, not only failed to procure that relief, which might have been expected from it under ordinary catarrhal or pneumonic ſymptoms, but in ſome caſes even proved prejudicial. Bliſters were applied to various parts with good effects: when there was pain in the breaſt or ſide, the application of them to the part affected was found very beneficial; and it was frequently thought proper to keep them open for ſome time. In ſome caſes, it was remarked, that a ſecond bliſter, applied a few days after the firſt, produced great relief, when the firſt had failed to do ſo. On account of the great debility, which ſeldom failed to accompany or follow the diſorder, bark and cordials were often deemed neceſſary, eſpecially towards the cloſe of the diſeaſe; but they would probably be deemed leſs neceſſary by the practitioners of the preſent day; for when a diſeaſed condition is removed, the conſtitution commonly recovers its ſtrength with rapidity, when care is taken the food be light and nutritious, and there is a free acceſs to pure air. See Medical Tranſact. vol. iii. art. 8.—Medical Communications, vol. i. art. 1.—Hiſt. de la Soc.

Royale de Med. de Paris, pout 1776.—Edin. Med. Eſſays, vol. ii. art. 2.—Rutty, Hiſt. of Weather.

INFORCED. } See { REINFORCED.
INFORCEMENT. } { REINFORCEMENT.

IN FORMA PAUPERIS, in *Law*. See FORMA *Pauperis*.

INFORMATION, for the king, is much the ſame with what is called declaration for a common perſon: it is not always done directly by the king or his attorney, or the clerk of the crown-office; but ſometimes by another, who ſues as well for the king as himſelf, on a breach of ſome penal law or ſtatute, wherein a penalty is given, one part to the uſe of the king, and another to the uſe of the informer. And it differs from an indictment, which is found by the oaths of twelve men; and is only the allegation of the officer who exhibits it. The latter ſort of informations, which are partly at the ſuit of the king, and partly at that of a ſubject, is a ſpecies of *qui tam* actions, ſo called becauſe they are brought by a perſon *qui tam pro domino rege*, &c. *quam pro ſeipſo in hac parte ſequitur*, and carried on by a criminal inſtead of a civil proceſs. By 31 Eliz. c. 5, no proſecution of this kind can be brought by any common informer, after one year is expired ſince the commiſſion of the offence; nor out of the country where the offence was committed; nor on behalf of the crown after the lapſe of two years longer; nor, where the forfeiture is originally given to the king alone, can ſuch proſecution be had after the expiration of two years from the commiſſion of the offence. It is alſo enacted by 18 Eliz. c. 5, that if any perſon, informing under pretence of any penal law, makes any compoſition without leave of the court, or takes any money or promiſe from the defendant to excuſe him, he ſhall forfeit ten pounds, ſtand two hours on the pillory, and be for ever diſabled to ſue on any popular or penal ſtatute. And by the ſame ſtatute, if a perſon exhibits his information only for vexation, the defendant may bring information againſt the informer. See COMPOUNDING *of Informations*.

Informations that are exhibited in the name of the king alone are of two kinds; thoſe which are truly and properly his own ſuits, and filed *ex officio* by his own immediate officer, the attorney-general; and thoſe, in which, though the king is the nominal proſecutor, yet it is at the relation of ſome private perſon or common informer; and they are filed by the king's coroner and attorney in the court of king's bench, uſually called the maſter of the crown-office, who, for this purpoſe, is the ſtanding officer of the public. The objects of the king's own proſecutions, filed *ex officio* by his own attorney-general, are properly ſuch enormous miſdemeanors as particularly tend to diſturb or endanger his government, or to moleſt or affront him in the regular diſcharge of his royal functions. The objects of the other ſpecies of information are any groſs and notorious miſdemeanors, riots, batteries, libels, and other immoralities of an atrocious kind. And when an information is filed in either of theſe ways, it muſt be tried by a petit jury of the county where the offence ariſes; after which, if the defendant be found guilty, he muſt be reſorted to the court for his puniſhment. Theſe informations, which are as ancient as the law itſelf (1 Show. 118.), of every kind, are confined by the conſtitutional law to mere miſdemeanors only, without extending to any capital offence. The oppreſſive uſe of information by the court of Star-chamber, &c. in the times preceding the Revolution, occaſioned a ſtruggle ſoon after the acceſſion of king William, to procure a declaration of their illegality by the judgment of the court of king's bench. But ſir John Holt, who then preſided there, and all the judges, were clearly of opinion, that this proceeding was founded on the common law, and could not then be impeached. However, in a few years afterwards, it was enacted by 4 & 5 W. & M. c. 18. that the clerk of the crown ſhall not file any information without expreſs direction from the court of king's bench; and that every proſecutor, permitted to promote ſuch information, ſhall give ſecurity by a recognizance of twenty pounds (a ſum now too ſmall), to proſecute the ſame with effect; and to pay coſts to the defendant, in caſe of his acquittal, unleſs the judge, who tries the information, ſhall certify there was reaſonable cauſe for filing it: and, at all events, to pay coſts, unleſs the information ſhall be tried within a year after iſſue joined. But there is a proviſo in this act, that it ſhall not extend to any other informations than thoſe which are exhibited by the maſter of the crown office: and, conſequently, informations at the king's own ſuit, filed by his attorney-general, are no way reſtrained thereby.

There is one ſpecies of informations, ſtill farther regulated by 9 Ann. c. 20, *viz.* thoſe in the nature of a writ of *quo warranto*, which is a remedy given to the crown againſt ſuch as had uſurped or intruded into any office or franchiſe. The modern information tends to the ſame purpoſe as the ancient writ, being generally made uſe of to try the civil rights of ſuch franchiſes; though it is commenced in the ſame manner as other informations are, by leave of the court, or at the will of the attorney-general; being properly a criminal proſecution, in order to fine the defendant for his uſurpation, as well as to ouſt him from his office; yet uſually conſidered at preſent as merely a civil proceeding.

An information on behalf of the crown, filed in the exchequer by the king's attorney-general, is a method of ſuit for recovering money or other chattels, or for obtaining ſatisfaction for damages in any perſonal wrong committed in the lands or poſſeſſions of the crown. (Moor, 375.) The moſt uſual informations are thoſe of *intruſion* and *debt*; the former being for any treſpaſs committed on the lands of the crown (Cro. Jac. 212. 1 Leon. 48. Savil. 49.), as by entering thereon without title, holding over after a leaſe is determined, taking the profits, cutting down timber, or the like; and the latter, upon any contract for monies due to the king, or for any forfeiture due to the crown upon the breach of a penal ſtatute. There is alſo an information *in rem*, uſually filed in the exchequer, where any goods are ſuppoſed to become the property of the crown, if no man appears to claim them, or to diſpute the title of the king. There is alſo another information, filed *ex officio* by the attorney-general, in the court of chancery, at the relation of ſome informant, called the relator, for the proper eſtabliſhment of charities, of which the king has the general ſuperintendance. Blackſt. Com. b. iii. and iv.

INFORMATUS NON SUM, or *Non ſum informatus*, a formal anſwer made of courſe by an attorney, who is commanded by the court to ſay any thing he thinks good in behalf of his client: who having nothing material to urge, makes anſwer, he is not informed: on which judgment paſſes for the other party.

INFORMER, INFORMATOR, a perſon that informs againſt, or proſecutes in any of the king's courts, thoſe that offend againſt any law or penal ſtatute. See INFORMATION.

INFORMIS, UNFORMED, that which has not the form or perfection it ſhould have.

INFORMES *Stellæ*, in *Aſtronomy*, are ſuch ſtars as have not yet been reduced into any conſtellation: otherwiſe called *ſporades*.

Of this kind there was a great number left by the ancient aſtronomers; but Hevelius, and ſome others of the moderns, have provided for the greater part of them, by making new conſtellations.

INFORTUNIUM, Homicide by. See Homicide.

INFRA, *Lat. below.* See Hypo.

INFRACTION, formed from *in* and the ſupine of *frango, I break*, a rupture or violation of a treaty, law, ordinance, or the like.

INFRALAPSARII, in *Eccleſiaſtical Hiſtory*, the name of a ſect of Predeſtinarians, who maintain, that God has created a certain number of men only to be damned, without allowing them the means neceſſary to ſave themſelves, if they would; and they are thus called, becauſe they hold that God's decrees were formed *infra lapſum*, after his knowledge of the fall, and in conſequence thereof; in contradiſtinction to the Supralapſarians.

INFRASCAPULARIS, in *Anatomy*, a name of the infraſpinatus muſcle. See the following article.

INFRASPINATUS, is a muſcle of the ſhoulder, called by the French ſous-epineux, and ſous-ſcapulo-trochitérien. It is placed at the back of the ſhoulder, covering that diviſion of the dorſum of the ſcapula which is below the ſpine, and extends from the baſis of the ſcapula to the great tubercle of the humerus. It is thick, broad, and triangular.

Its poſterior ſurface is covered above and on the outſide by the deltoid; above and within by the trapezius, and below by the latiſſimus dorſi: in the reſt of this ſurface it is covered by the ſkin. A thin aponeuroſis, common to this muſcle and the teres minor, immediately inveſts its poſterior ſurface. This aponeuroſis is continuous above with thoſe of the trapezius and deltoid, it is attached on the inſide to the baſis of the ſcapula; is continuous below, with a ſeptum placed between the two teres muſcles and the infraſpinatus; and is fixed on the outſide to the poſterior edge of the inferior margin of the ſcapula.

Its anterior ſurface covers the ſcapula below the ſpine, to the poſterior three-fourths of which it is attached. It is ſeparated from the anterior fourth of this lower diviſion of the ſcapula by the ſuperior and external ſcapular veſſels, by the ſcapular nerve, and by cellular ſubſtance. Beyond the ſcapula this ſurface of the muſcle covers the ſhoulder joint, to the orbicular ligament of which it is ſtrongly connected. The inner edge is fixed to the baſis of the ſcapula, from the ſpine almoſt to the inferior angle. Its upper edge is attached to the lower ſurface of the ſpine of the ſcapula, and to the aponeuroſis of the deltoid: the outer portion of this margin is parallel to the inferior edge of the ſupraſpinatus. The lower border is oblique from below upwards, and from within outwards. This is united to the teres major by an aponeurotic ſeptum, which is ſoon divided into two layers: one of theſe paſſes between the two teres muſcles, the other between the teres minor and infraſpinatus. The lower border of the latter is then united to the teres minor through about half its length; for the reſt of their extent they are ſeparated by a cellular line. In many ſubjects the fibres of theſe two muſcles are ſo confounded at this part, that they cannot be ſeparated.

The ſuperior and inferior edges are united at a truncated angle, which is large and thick, and attached to the middle of the great tubercle of the humerus.

The infraſpinatus muſcle is compoſed of tendinous and muſcular parts. It is attached to the humerus by a broad and thick tendon, which expands into an aponeurotic plane continued into the ſubſtance of the muſcle beyond its middle, and nearer to the poſterior than to the anterior ſurface of the muſcle. The muſcular fibres ariſe from the dorſum of the ſcapula, from the under ſurface of its ſpine, from the aponeuroſis of the deltoid, and from the aponeurotic ſeptum, which ſeparates this from the two teres muſcles. They join the common tendon, which they accompany nearly to the humerus, purſuing, however, very different directions. The ſuperior fibres proceed nearly horizontally from within outwards: all the others are oblique from within outwards, and from below upwards, and their obliquity increaſes as they are placed lower down. Thoſe fibres, which ariſe from the aponeuroſis of the deltoid, and from the lower ſurface of the ſpine of the ſcapula, deſcend ſlightly, and terminate on the poſterior ſurface of the tendon, on which they are extended almoſt to its attachment to the humerus.

The motions which this muſcle can produce in the humerus, differ according to the poſition of that bone. When the arm is hanging by the ſide, the humerus will be moved on its axis, ſo as to be turned from before outwards and backwards. If the humerus has been previouſly elevated, the infraſpinatus will carry it backwards. When the arm is fixed, this muſcle will draw the ſcapula, and through it the trunk alſo, forwards. The ſtrength and breadth of its tendon enable it to ſupport the head of the humerus, and to prevent it from being thrown out of the glenoid cavity, when the arm is moved ſuddenly forwards.

INFULA, a name anciently given to one of the pontifical ornaments worn on the head. Feſtus tells us that the infulæ were filaments or fringes of wool, covering that part of the head where the hair grows as far as the temples, whence, on each ſide, hung down two ſtrings called *vittæ*, for binding it, wherewith the ancients uſed to adorn their prieſts, their victims, and even their temples. The infula was the ſame thing to prieſts that the diadem was to kings; *viz.* the badge of their dignity and authority. The difference in ſhape between the diadem and the infula conſiſted in this, that the diadem was flat and broad, and the infula was rounded and twiſted.

INFUMA, or Dikjeschoft, in *Geography*, a town of Africa, in the kingdom of Anté, where the Engliſh built a fort in 1691.

INFUNDIBULA *of Birds.* See *Anatomy of* Birds.

INFUNDIBULIFORM Flowers, in *Botany*, are ſuch as reſemble the figure of a funnel; being broad and ample at top, and contracted into a neck at bottom; ſuch as that of the bear's ear, or auricula.

INFUNDIBULUM, a Latin word ſignifying a *funnel*; whence divers parts in the human body, having a reſemblance thereto in ſhape, are called by the ſame name.

Hence alſo certain parts of plants are called *infundibuliformes*.

The word infundibulum is alſo uſed by the metallurgic writers to ſignify a veſſel of a conic ſhape, uſed to pour a melted metal out of the crucible into.

Infundibulum, in *Anatomy*, a ſmall proceſs in the brain. See Brain.

INFUSION, in *Pharmacy*, an operation whereby the virtues of plants, roots, and the like are drawn out by letting them ſteep in ſome convenient fluid menſtruum without boiling them therein; ſince boiling is found to diſſipate the finer parts of many bitter and aromatic ſubſtances, without carefully extracting their medicinal principles.

Infuſion is uſed in bodies of a lax texture, whoſe parts are ſo light as not to admit of a greater motion without hazard of flying away in vapour.

Its chief uſe is to communicate the virtues of bodies to liquors, either in order to regulate their force, or correct their ill qualities.

Some infuſions are made in common water, others in wine, vinegar, milk, ſpirit of wine, &c. Boiling water is ſometimes effuſed upon any ſubſtance, and allowed to ſtand upon it for ſome time. Water is alſo occaſionally effuſed cold in the ſame manner; and in this caſe the ſpecific form of cold infuſion is uſed.

The ſame operation is applicable to thoſe ſubſtances which contain any parts volatile in the heat of 212°, to the ſeparation of more readily ſoluble conſtituent parts from thoſe which are leſs ſo, and to the preparation of ſlighter impregnations than boiling for a length of time produces. The boiling temperature of the water is ſo ſoon loſt in this mode of application, that even with the moſt delicate ſubſtances it does no injury, and it aſſiſts in looſening the texture of the vegetable, and effecting the ſolution much ſooner than cold water alone does. Infuſions are uſually matters of extemporaneous preſcription, and cannot generally be kept ready prepared in the ſhops without ſpoiling. Their number has been extended to moſt of the articles in common uſe, and the ſtrength of each is accommodated to the moſt uſual ſtandards of practice. We ſhall recite ſome of the principal.

The *bitter infuſion* is prepared by cutting the tops of the leſſer centaury and chamomile flowers of each half an ounce, and the yellow rind of lemon and orange peel, of each two drams, in ſmall pieces, and infuſing them in a quart of boiling water. A tea-cupful of this infuſion may be taken twice or thrice a day for indigeſtion, weakneſs of the ſtomach, or want of appetite.

Infuſion of the Bark is made by infuſing an ounce of the powder in a pint of boiling water, with the addition of four or five table-ſpoonfuls of brandy, for two or three days. In diſorders which require the bark, a tea-cupful of this may be taken two or three times a day.

Infuſion of Calumba, infuſum Calumbæ, is prepared by ſlicing a dram of Calumba root, and macerating it for two hours in half a pint of boiling water in a covered veſſel, and ſtraining it. See Columbo.

Infuſion of Camomile, infuſum anthemidis, is made by macerating for ten minutes, in a covered veſſel, two drams of camomile flowers in a pint of boiling water, and ſtraining.

Infuſion of Carduus is made by infuſing an ounce of the dried leaves of carduus benedictus in a pint of common water for ſix hours, without heat, and then filtering the liquor through paper. This infuſion, which may be flavoured at pleaſure with cinnamon, or other aromatics, may be beneficially uſed in weakneſſes of the ſtomach, where the common bitters do not agree.

Infuſion of Caſcarilla is prepared by macerating for two hours, in a covered veſſel, half an ounce of Caſcarilla bark bruiſed in half a pint of boiling water, and ſtraining. See Cascarilla.

Infuſion of Catechu is obtained by taking 2½ drams of extract of catechu, and half a dram of bruiſed cinnamon bark, macerating them for an hour, in a covered veſſel, in half a pint of boiling water, and ſtraining. See Catechu.

Infuſion of Cinchona, infuſum cinchonæ, is obtained by macerating for two hours, in a covered veſſel, half an ounce of lance-leaved Cinchona bark in half a pint of boiling water, and ſtraining.

Infuſion of Cloves, infuſum caryophyllorum, is obtained by macerating for two hours, in a covered veſſel, a dram of cloves bruiſed in half a pint of boiling water, and ſtraining.

Infuſion of Cuſparia is procured by macerating for two hours, in a covered veſſel, two drams of bruiſed Cuſparia bark in half a pint of boiling water, and ſtraining.

Infuſion of Fox-glove, infuſum digitalis, is obtained by macerating for four hours, in a covered veſſel, a dram of purple fox-glove leaves, dried and powdered, in half a pint of boiling water, and ſtraining; then adding half a fluid-ounce of ſpirit of cinnamon. See Digitalis.

Infuſion, Compound, of Gentian, infuſum amaram ſimplex, P. L. 1745, is procured by macerating in a covered veſſel, gentian root ſliced and orange-peel dried, of each a dram, two drams of freſh lemon-peel, in twelve ounces of boiling water, and ſtraining.

Infuſion, Compound, of Horſe-radiſh, infuſum armoraciæ compoſitum, is procured by macerating for two hours, in a covered veſſel, freſh horſe-radiſh root ſliced, and muſtard ſeeds bruiſed, of each an ounce, in a pint of boiling water, and ſtraining; then adding a fluid-ounce of compound ſpirit of horſe-radiſh. An infuſion for the palſy may be made by infuſing horſe-radiſh root ſhaved, muſtard ſeed bruiſed, of each four ounces; and one ounce of the outer rind of orange-peel in two quarts of boiling water, in a cloſe veſſel for twenty-four hours. A tea-cupful of this warm ſtimulating medicine may be taken three or four times a day, in paralytic complaints. It excites the action of the ſolids, proves diuretic, and, with warmth, promotes perſpiration. If two or three ounces of the dried leaves of marſh-trefoil be uſed inſtead of the muſtard, we ſhall have the antiſcorbutic infuſion.

Infuſion of Linſeed, infuſum lini, is prepared by infuſing two ſpoonfuls of linſeed, or an ounce of linſeed bruiſed, and half an ounce of liquorice root ſliced, in two pints of boiling water by the fire for four hours, and then ſtraining off the liquor. The pectoral infuſion is made by adding to theſe ingredients an ounce of the leaves of colt's-foot. Theſe emollient liquors may be taken in difficulty of making water, and in coughs and other complaints of the breaſt.

Infuſion of Quaſſia is obtained by macerating for two hours, in a covered veſſel, a ſcruple of quaſſia-wood ſliced, in half a pint of boiling water, and ſtraining. See Quassia.

Infuſion of Rhubarb, infuſum rhei, is procured by macerating for two hours, in a covered veſſel, a dram of ſliced rhubarb-root in half a pint of boiling water, and ſtraining. See Rhubarb.

Infuſion of Roſes, infuſum roſæ, tinctura roſarum, P. L. 1718, tinctura roſarum rubrarum, P. L. 1720, is made by infuſing half an ounce of the petals of red roſes, dried, in 2½ pints of boiling water; afterwards pouring in three fluid-drams of dilute ſulphuric acid, and 1½ ounce of double refined ſugar. Pour the water upon the petals of the roſe in a covered glaſs veſſel: then add the acid, and macerate for half an hour. Laſtly, ſtrain the infuſion, and add the ſugar to it. A tea-cupful of this aſtringent infuſion may be taken every three or four hours, in an exceſſive flow of the menſes, vomiting of blood, and other hæmorrhages. It will likewiſe ſerve as a very good gargle.

Infuſion of Senna, infuſum Sennæ, is prepared by macerating for an hour, in a covered veſſel, 1½ ounce of Senna leaves, a dram of ſliced ginger-root, in a pint of boiling water, and ſtraining the liquor. An infuſion of Senna, named "infuſum Sennæ tartarizatum," may be had by adding extemporaneouſly to each pint of the infuſion two drams of ſupertartrate of potaſs, in ſuch proportions as circumſtances may require.

Infuſion of Senna and Tamarinds, is prepared by infuſing for four or five hours one ounce of tamarinds and ſenna, and cryſtals of tartar, of each two drams, in a pint of boiling water; ſtraining the liquor, and adding to it an ounce or two of the aromatic tincture. Perſons who are eaſily purged, may leave out either the tamarinds or the cryſtals of tartar. A tea-cupful of this agreeable cooling-purge may be taken every half hour till it operates.

Infuſion of Simarouba is made by macerating for two hours, in a covered veſſel, half a dram of Simarouba bark, bruiſed, in half a pint of boiling water, and ſtraining. See SIMAROUBA.

Infuſion, Spaniſh, is made by infuſing an ounce of Spaniſh juice cut into ſmall pieces, and three drams of ſalt of tartar in a quart of boiling water for a night; and adding to the ſtrained liquor an ounce and a half of the ſyrup of poppies. In recent colds, coughs, and obſtructions of the breaſt, a tea-cupful of this infuſion may be taken with advantage three or four times a day. See LIQUORICE.

Infuſion of Tobacco, infuſum tabaci, is made by macerating for an hour, in a covered veſſel, a dram of tobacco leaves in a pint of boiling water, and ſtraining. This infuſion is intended to be uſed as a clyſter, to which purpoſe it is often directed.

INFUSION is alſo uſed to ſignify the action of conveying liquor into the body by the veins. See INJECTION.

Some phyſicians have found out a new method of purging, by infuſing a cathartic into the veins, which operates pretty much after the manner of a clyſter.

ING, in *Agriculture*, a provincial term, employed to ſignify a common paſture or meadow which lies low or wet, and which is chiefly employed as hay lands.

INGA, in *Botany*. See MIMOSA.

INGANNO, *Ital.* a trick, a diſappointment, a diſappointed cadence, or cloſe, is, when, after preparing for a regular termination, ſome unexpected chord or modulation occurs to lengthen the movement and poſtpone the cadence. See CADENCE.

INGARD POINT, in *Geography*, a cape of Ireland, on the ſouth coaſt of the county of Wexford, within which lies the ſmall dry harbour of Feathard, which is only fit for ſmall veſſels.

INGARYD, a town of Sweden, in the province of Smaland; five miles S. of Jonkioping.

INGATESTONE, a ſmall town in the hundred of Chelmsford and county of Eſſex, England, is ſituated 23 miles from London, on the high road to Colcheſter. It conſiſts principally of one ſtreet, and contained, according to the late return to parliament, 120 houſes and 645 inhabitants. In the church, which has a high embattled brick tower, are ſeveral elaborate monuments of the Petre family, whoſe burial place adjoins the chancel on the north ſide. A conſiderable market was formerly held here, but having greatly declined, it has been for ſeveral years wholly diſcontinued; but a very large fair for Scotch and Welch cattle is ſtill held on the firſt of December, annually. An alms-houſe, for ſeven women and three men, was founded, in the year 1557, by ſir William Petre, and endowed by him to the amount of 90*l.* 13*s.* 4*d.* per annum.

Near the town is Ingateſtone-hall, a venerable, but irregular ſtructure, which was the family reſidence of the lords Petre, previous to the building of a new manſion at Weſt Thorndon. Beauties of England and Wales, vol. v.

INGATORP, a town of Sweden, in the province of Smaland; 40 miles N. of Wexio.

INGELFINGEN, a town of Germany, in the principality of Hohenloe, on the Kocher; eight miles N. E. of Ohrenburg.

INGELHEIM, OBER, a town of France, in the department of Mont Tonnerre, ſituated on the Selz; 12 miles W. of Mentz. N. lat. 49° 56′. E. long. 8° 1′.

INGELHEIM, *Nider*, a town of France, in the department of Mont Tonnerre, one mile from Ingelheim Ober.

INGELLY, a town of Hindooſtan, in Bengal, at the mouth of the Hoogly; 60 miles S. of Calcutta.

INGELMUNSTER, a town of France, with a caſtle, in the department of the Lys, and chief place of a canton, in the diſtrict of Courtray; five miles N. of Courtray. The town contains 4873, and the canton 14,284 inhabitants, on a territory of 52½ kiliometres in four communes.

INGELSBURG, a town of Saxony, in the Vogtland; nine miles S.S.E. of Oelſnitz.

INGELSTAD, a town of Sweden, in the province of Smaland; 10 miles S.E. of Wexio.

INGEMINATED FLOWERS, are thoſe where one flower ſtands on, or naturally grows out of another; called alſo proliferous flowers.

INGEN, in *Geography*, a ſmall iſland in the North ſea, near the coaſt of Lapland. N. lat. 70° 56′.

INGENDRING. See ENGENDERING.

INGENERATE, in *Natural Hiſtory*, is a term uſed to expreſs the kind of petrifactions produced by intromiſſion, or the introduction of the mineral particles into the internal texture of the original organized. Martin's "Outlines," p. 67.

INGENHOUZ, JOHN, in *Biography*, an eminent phyſician and chemiſt, was born at Breda in the year 1730. Little is known of his early life; but in 1767 he came to England with a view of obtaining information on the Suttonian method of inoculation for the ſmall-pox, and in the following year he went, on the recommendation of the late ſir John Pringle, to Vienna, to inoculate the archducheſs Thereſa-Elizabeth, only daughter of Joſeph II., and the archdukes Ferdinand and Maximilian, brothers of the emperor. For theſe ſervices he obtained rewards and honours: he was made body-phyſician and counſellor of ſtate to their imperial majeſties, with a penſion of 600*l.* per annum. In the following ſpring he went to Italy, and inoculated the grand duke of Tuſcany: after this he returned to England, to which he was much attached, where he ſpent his time in ſcientific purſuits. He publiſhed a very valuable work, entitled "Experiments on Vegetables, diſcovering their great power of purifying the common air in ſunſhine, but injuring it in the ſhade and night." This work was firſt publiſhed in 1779, and has been frequently referred to by Dr. Prieſtley and others, who have carried their obſervations much farther. It was tranſlated into the French and German languages, and highly eſteemed by all the experimental philoſophers of that period. He aſcertained, that not only from the green matter found on ſtagnant waters, but likewiſe from the leaves of vegetables, from the green branches and ſhoots, even from the entire vegetable, when placed under water and expoſed to the ſolar light, oxygen gas, in a ſtate generally of great purity, is evolved; and as the reſult of his numerous experiments he adopted the concluſion, that oxygen is elaborated in the leaves and other organs of vegetables, by a vital action excited and ſuſtained by the ſolar light. The doctor, through the whole of life, was fond of exhibiting among his friends, particularly young perſons, experiments of this kind, which required ſcarcely any apparatus, excepting a bell glaſs and a phial or two, and with the oxygen gas which he obtained from cabbage leaves or other vegetables, he would exhibit the combuſtion of iron wire, which is a ſtriking and very brilliant experiment. Dr. Ingenhouz was author of many papers inſerted in the Tranſactions of the Royal Society, of which body he was an active and uſeful member. Of theſe papers we may notice the following: Experiments on the torpedo:—Methods of meaſuring the diminution of bulk taking place on the mixture of nitrous with common air:—Experiments on the electrophorus:—New Methods of ſuſpending magnetic needles: —Conſiderations on the influence of the vegetable kingdom on the animal creation. He died in the year 1799, highly eſteemed for the ſimplicity of his manners, and for the diſcoveries which he had made in the ſeveral departments of experimental philoſophy. Monthly and Gentleman's Magazine. Murray's Chemiſtry.

INGENITE, Inborn, ſignifies any diſeaſe or habit which comes into the world with a perſon, nearly the ſame with hereditary.

INGENUITAS Regni, anciently ſignified the freeholders and commonalty of the kingdom: the title was alſo ſometimes given to the barons and lords of the king's council.

INGENUOUS, Ingenuus, among the Romans, a title applicable to a perſon born free, or of free parents.

Iſidore ſays, they are called *ingenui, qui libertatem habent in genere non in facto*; thoſe who are born free, not thoſe who acquire their freedom.

A perſon was accounted ingenuous, if only the mother were free, and the father a ſlave.

Theſe could give their votes, and enjoy offices, from which the *liberti*, or freedmen, &c. were debarred.

Ingenuous is ſometimes alſo uſed to ſignify a native of a country in contradiſtinction to a foreigner.

INGERAM, in *Geography*, a ſmall iſland in the ſtraits of Malacca, near the coaſt of Salengore. N. lat. 3° 15′. E. long. 101° 26′.—Alſo, a town of Hindooſtan, in the circar of Rajamundry; 30 miles S.E. of Rajamundry.

INGETORP, a town of Sweden, in the province of Schonen; 10 miles E. of Yſtad.

INGINEER, or Engineer. See Engineer.

INGKALU, in *Geography*, a ſmall iſland in the North ſea, near the coaſt of Lapland. N. lat. 70° 50′.

INGLEBOROUGH, a mountain of England, in the N.W. part of the county of York, ſaid to be 20 miles in circumference. The height is ſtated by Houſman to be 3987 feet; but by the barometrical meaſurement of Mr. Ewart 2377.12, and by trigonometrical meaſurement 2380.7 feet above the level of the ſea.

INGLOTT, William, in *Biography*, an organiſt of the cathedral church of Norwich, who ſeems, by an inſcription on his monument in that church honourable to his memory, to have been a man of no common abilities. We have never heard or ſeen any of his productions; but in all probability, Dr. Croft had; who, a hundred years after his deceaſe, had his monument repaired. Inglott died in 1621.

INGLUVIES. See Craw.

INGOLSTADT, in *Geography*, a town of Bavaria, ſituated on the Danube, and ſurrounded with a moraſs. It has an univerſity, founded in the year 1472, which embraced the Reformation in 1743; 37 miles N. of Munich. N. lat. 48° 43′. E. long. 11° 22′.

INGOT, a maſs or lump of gold or ſilver, from the mines, melted down, and caſt in a ſort of mould, but not coined or wrought.

The word ſeems formed from the French *lingot*, which ſignifies the ſame.

Ingot is alſo a name given to the moulds or cavities, wherein they caſt melted metals, or regulus of ſemimetals.

INGOULT, Nicholas Louis, in *Biography*, a French Jeſuit, was born at Giſors, devoted himſelf to an eccleſiaſtical life, and became a very eloquent preacher. He publiſhed the eighth volume of the Memoirs of the Miſſions of the Society of Jeſus in the Levant. He was author alſo of ſermons which were highly applauded. He died in 1753.

INGOUVELLE, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the diſtrict of Le Havre. The place contains 5500, and the canton 10,347 inhabitants, on a territory of 40 kiliometres, in ſix communes.

INGRAFTING, or Engrafting. See Engrafting.

INGRAILED. See Engrailed.

INGRAM, Robert, in *Biography*, was born in Yorkſhire, and educated at Beverley ſchool, from whence he was ſent to Corpus Chriſti college, Cambridge, of which he became fellow, and took there his degrees in arts. His firſt preferment was the perpetual curacy of Bridhurſt, in Kent, after which he obtained ſucceſſively the ſmall vicarage of Orſton, in Nottinghamſhire, and the vicarages of Wormington and Boxted, in Eſſex. He died in 1804, leaving behind him a high character for ſimplicity of manners, great integrity, and genuine benevolence. He had a high ſenſe of the dignity and importance of the clerical functions, and for 50 years of his life was indefatigable in his attention to profeſſional duties. He was author of "A view of the great events of the ſeventh plague, or period, when the myſtery of God ſhall be finiſhed." "Accounts of the ten tribes of Iſrael being in America, originally publiſhed by Manaſſeh Ben Iſrael, &c." "A complete and uniform explanation of the prophecy of the ſeven vials of wrath, or ſeven laſt plagues contained in the Revelations of St. John, &c."

INGRASSIAS, John Philip, was a native of Sicily. He ſtudied medicine at Padua, where he took the degree of doctor in medicine in the year 1537, with ſingular reputation; inſomuch that he ſoon received ſeveral invitations to profeſſorſhips from different ſchools in Italy. He accepted the chair of medicine and anatomy at Naples, which he occupied for a number of years, lecturing to the moſt crowded audiences drawn by his fame from all parts of the country. He poſſeſſed peculiar qualifications for the office, having united a conſummate knowledge of the writings of the ancient phyſicians with great practical ſkill and a ſound judgment, which led him to eſtimate juſtly the merits and defects of thoſe fathers of the art. A ſingular teſtimony of his talents and unremitting attention to the improvement of his pupils was given by the latter, who cauſed his portrait to be placed in the ſchools of Naples with the following inſcription: "Philippo Ingraſſiæ Siculo, qui veram medicinæ artem et anatomen, publicè enarrando, Neapoli reſtituit, Diſcipuli memoriæ cauſa, P. P." At length he quitted his ſituation at Naples in order to return to his native iſland, where he ſettled at Palermo. Here alſo he received many marks of public diſtinction. The rights of citizenſhip were conferred upon him; and in 1563, Philip II. king of Spain, appointed him firſt phyſician for Sicily and the adjacent iſles. By virtue of the powers attached to this office he reſtored order in the medical conſtitution of the country, by preventing all perſons, unqualified by their education and abilities, from practiſing there. His zeal for the credit of his profeſſion rendered him rigid and ſevere in his examination of candidates; and he exerciſed his art himſelf in the moſt honourable manner. When the plague raged at Palermo in 1575, he adopted ſuch excellent regulations, in quality of deputy of health and firſt conſultant, that he put a ſtop to the calamity, and reſtored the city to health, and was hailed by all the citizens, the Sicilian Hippocrates. The magiſtrates were ſo grateful for his ſervices, that they voted him a reward of two hundred and fifty gold crowns a month: but he diſintereſtedly declined to accept any more than what ſerved for the maintenance and decoration of the chapel of St. Barbe, which he had built in the cloiſter of the Dominican convent of Palermo. He died greatly regretted in 1580, at the age of 70 years.

Ingraſſias cultivated anatomy with great aſſiduity, and is eſteemed one of the improvers of that art, eſpecially in regard to the ſtructure of the cranium, and the organ of hearing. He diſcovered the ſmall bone of the ear, called the *ſtapes*, which has been claimed as the diſcovery of others, but is admitted even by Fallopius to have been his. He deſcribed minutely the cavity of the *tympanum*, the *feneſtra rotunda* and *ovalis*, the *cochlea*, ſemicircular canals, maſtoid cells, &c.; and Eloy thinks, from a view of his plates, that he was acquainted with the muſcle of the *malleus*, the diſcovery of which is aſcribed to Euſtachius. He is ſaid alſo to have diſcovered the ſeminal veſicles. He was author of the following works: 1. "Jatropologia; Liber quo multa adverſus Barbaros Medicos diſputantur," Venice, 1544, 1558, 8vo.—2. "Scholia in Jatropologiam," Naples, 1549, 8vo.—3. "De Tumoribus præter naturam," *ibid.* 1553, folio, vol. i. This is properly a commentary on ſome of the books of Avicenna.—4. "Raggionamento fatto ſopra l'infermita epidemica dell' anno 1558," Palermo, 1560, 4to., together with "Trattato di due moſtri nati in Palermo in diverſi tempi."—5. "Conſtitutiones et Capitula, necnon Juriſdictiones Regii Proto-Medicatûs officii, cum Pandectis ejuſdem reformatis," Palermo, 1564, 1657, 4to.—6. "Quæſtio de purgatione per medicamentum, atque obiter etiam de ſanguinis miſſione, an ſextâ die poſſit fieri," Venice, 1568, 4to.—7. "Galeni Ars Medica," *ibid.* 1573, folio.—8. "De frigidæ potu poſt medicamentum purgans Epiſtola," *ibid.* 1575, 4to., reprinted at Milan, 1586.—9. "Informatione del peſtifero e contagioſo morbo, il quale afflige e habe afflito la citta di Palermo, e molte altre citta e terre del regno di Sicilia, nell' anno 1575 e 1576," Palermo, 1576, 4to. This work was tranſlated into Latin by Joachim Camerarius, and publiſhed under the title of "Methodus curandi peſtiferum contagium," at Nurimberg, 1583.—10. "In Galeni Librum de oſſibus doctiſſima et expertiſſima Commentaria," a poſthumous publication, printed at Meſſina, in 1603, under the inſpection of his nephew, Nicholas Iugraſſias. This, which may be deemed the principal work of Ingraſſias, contains the text of Galen, in Greek and Latin, with a very diffuſe and learned commentary, in which there is much minute and accurate deſcription, particularly of the parts belonging to the organ of hearing. The figures are thoſe of Veſalius. The author defends Galen as far as he is able, but not againſt the truth of modern diſcovery. See Eloy. Dict. Hiſt. Gen. Biog. Haller Bibl. Anatom.

INGRAVING, or Engraving. See Engraving.

INGRE, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the diſtrict of Orleans; four miles N. W. of Orleans. The place contains 2905, and the canton 10,810 inhabitants, in a territory of 16 kiliometres, in 10 communes.

INGREDIENTS, all the ſimples which go into the compoſition of any medicine, ointment, ſauce, or the like.

INGRESS, in *Aſtronomy*, the ſun's entering the firſt ſcruple of one of the four cardinal ſigns, eſpecially Aries.

Ingreſs, *Egreſs*, and *Regreſs*, in *Law*, are words in leaſes of land, ſignifying a free entry into, a going out of and returning from ſome part of the premiſes leaſed to another; as to get in a crop of corn, &c. after the term expired.

INGRESSU, a writ of entry, whereby a perſon ſeeks entry into lands or tenements. It lies in various caſes, and has various forms. It is alſo called *precipe quod reddat*.

INGRIA, or Ingermanland, in *Geography*, that part of Ruſſia, which was wreſted by Peter the Great from the Swedes, and confirmed to Ruſſia at the peace of Nyſtadt in 1721. It is now called the "Government of St. Peterſburg;" which ſee.

INGRIN, or Grain, a town of Africa, in the country of the Foulahs; 30 miles S.W. of Cayor.

INGROSSATOR *Magni Rotuli*, is the ſame as clerk of the pipe.

INGROSSER, or Engroſſer, in *Common Law*, is one who buys up corn growing, or any proviſions by wholeſale, before the market, to ſell again. See Foreſtalling.

It alſo ſignifies a clerk, who writes records, or inſtruments of law, on ſkins of parchment. See Engroſſing.

INGROSSING *of a Fine*, is the making the indentures by the chirographer, for delivery of them to the party to whom the fine is levied.

INGROWITZ, in *Geography*, a town of Moravia, in the circle of Brunn; 30 miles N.N.W. of Brunn. N. lat. 49° 36'. E. long. 16° 2'.

INGSKAR, a ſmall iſland in the gulf of Bothnia. N. lat. 61° 15'. E. long. 17° 24'.

INGUE-LOUKA, a town of Chineſe Tartary. N. lat. 42° 16'. E. long. 124° 44'.

INGUEN, in *Anatomy*, the technical term for the groin.

INGUIMBERTI, Dominic-Joseph-Mary d', in *Biography*, a learned French prelate, was born at Charpentras in 1683. He devoted himſelf from a very early age to the eccleſiaſtical profeſſion, became a member of the Dominicans, and afterwards joined the Ciſtercians, in order that he might ſubmit to what he conceived the more perfect rules of monaſtic diſcipline. In this laſt order his merits raiſed him to the higheſt offices of honour and confidence. Being deputed to Rome on the buſineſs of his monaſtery, he ſo highly recommended himſelf to the eſteem of pope Clement XII. that in the year 1733, he was raiſed to the rank of biſhop of Charpentras, and other eccleſiaſtical preferment. He died in the year 1757, and is known in the republic of letters by ſeveral original works, and tranſlations of others. As a biſhop he obtained univerſal reſpect, and employed his wealth in ſerving the public and in relieving the poor. He built a large and noble hoſpital, and he collected the moſt extenſive and valuable library in Provence, which he gave for the uſe of the public.

INGUINAL Glands, in *Surgery*. See Glands.

Inguinal *Hernia*, a rupture, or protruſion of the bowels at the abdominal ring; a bubonocele. See Hernia.

Inguinal *Ligament*. This, which has been alſo called from its diſcoverer ligamentum Fallopii, is an aponeurotic, or ligamentary band, faſtened by one end to the anterior and ſuperior part of the os ilium, and by the other to the ſpine of the os pubis. The middle portion of it is very narrow, but it expands conſiderably towards both its extremities. It is cloſely joined to the muſcles of the abdomen, and to the aponeurotic faſcia of the thigh, but ſeems to be often wanting.

INGUINALIS, in *Anatomy*, an epithet ſometimes applied to the external iliac artery and vein.

INGUL, in *Geography*, a river of Ruſſia, which runs into the Bug, near Matvievka.

INGULETZ, a river of Ruſſia, which runs into the Dnieper; 12 miles N.E. of Cherſon.

INGULPHUS, in *Biography*, a monaſtic hiſtorian, was the ſon of a courtier of Edward the Confeſſor, and was born at London about 1030. He purſued his maturer ſtudies at Weſtminſter and Oxford, and diſtinguiſhed himſelf as a great adept in the Peripatetic philoſophy. Scarcely had he attained the age of manhood when he was appointed ſecretary to duke William, by whoſe permiſſion he viſited the Holy Land and Conſtantinople in 1064, and upon his return, he entered into the order of the Benedictines at the abbey of Fontenelle, in Normandy, of which he became prior. When his patron, William, obtained the crown of England, Ingulphus was created abbot of the rich monaſtery of Croyland, which being in a dilapidated ſtate, he rebuilt, and for which he obtained many privileges. He died in 1109, leaving behind him as evidences of his great learning, a work on the life and miracles of St. Guthlac, and a hiſtory of the monaſtery of Croyland. The laſt gives the author rank with the Engliſh hiſtorians. It was publiſhed at London, by ſir Henry Saville, among the quinque ſcriptores, in 1596, being almoſt five hundred years after the death of the author. It has been ſeveral times reprinted: the beſt edition is that of Oxford, in 1684.

INGULSK, in *Geography*, a town of Ruſſia, in the government of Ekaterinoſlav, on the Ingul; 28 miles S. of Elizavet.

INGURTY, a town of Hindooſtan, in the province of Golconda; 22 miles S.E. of Warangole.

INGWEILER, a town of France, in the department of the Lower Rhine, on the Motter; 21 miles N.N.W. of Straſburg.

INHALER, in *Surgery*, a machine lately invented by Mr. Mudge, and ſo contrived, that the air drawn through a tube in reſpiration, paſſes firſt through hot water, and thus comes to the lungs loaded with warm vapour. The ſame air, when expelled in expiration, paſſes back through the tube, and thence through a valve, when by proper management it may be diſtributed over the ſurface of the body and thus act as a vapour-bath. The author's directions for the proceſs are as follow:

In the evening, a little before bed-time, the patient, if of adult age, is to take three drams, or as many tea-ſpoonfuls of elixir paregoricum in a glaſs of water: if the ſubject is younger, *e.g.* under five years old, one tea-ſpoonful; or within that and ten years, two. About three quarters of an hour after he ſhould go to bed, and being covered warm, the inhaler, filled three parts with water nearly boiling, and wrapped up in a napkin, but ſo that the valve in the cover is not obſtructed by it, is to be placed at the arm-pit, and the bed-cloaths being drawn up, and over it cloſe to the throat, the tube is to be applied to the mouth, and the patient ſhould inſpire and expire through it about twenty minutes or half an hour. This, he aſſures us, is an infallible and immediate cure for the cough conſequent on catching cold. Mudge's radical and expeditious Cure for a recent Catarrhous Cough, 1778.

INHALLOW, in *Geography*, one of the ſmaller Orkney iſlands, between Pomona and Rouſa.

INHAMBANE, or INNANBAM, a kingdom of Africa, in the country of Mocaranga, bounded N. by Sabia, E. and S.E. by the Indian ſea, S.W. by the river Manica, and N.W. by an unknown country.

INHAME, in *Botany*. See DIOSCOREA.

INHAMOIT, in *Geography*, a town and diſtrict of Africa, in the country of Mocaranga, ſituated about S. lat. 17° 30′. E. long. 31° 20′.

INHAMPURA, a river of Africa, in the kingdom of Inhambane, which runs into the Indian ſea, S. lat. 24° 30′.

INHANBANO, a river of Africa, which runs into the Indian ſea, S. lat. 23° 15′.

INHANGOMA, an iſland of Africa, in the river Zambeze. S. lat. 17° 45′. E. long. 32° 20′.

INHANZARA, a town of Nubia, in Sennaar; 30 miles from Gieſſen.

INHAQUEA, a town of Africa, in the kingdom of Sofala, poſſeſſed by the Portugueſe, near the ſea-coaſt; 20 miles S.W. of Sofala.

INHARMONICAL RELATION, in *Muſic*. See RELATION, *inharmonical*.

INHARMONICAL, is ſaid of an interval or chord that is impracticable in harmony, and, conſequently, in melody. Notes out of tune are inharmonical.

INHARMONIOUS, or unnatural relations, according to Mr. John Holden (Eſſay, p. 331.) are ſuch intervals as reſult from the ſums of notes or intervals not contiguous in the ſcale, as a minor third to a major ſeventh, &c.

INHASATO, in *Geography*, a ſmall iſland in the Indian ſea, near the coaſt of Africa. S. lat. 20° 35′.

INHERENCE, in *Philoſophy*, is applied to the juncture or connection of an accident with its ſubſtance.

Thus quantity has a neceſſary inherence in a natural body.

INHERENT, in *Natural Hiſtory*, is a term uſed by Mr. William Martin (Outlines, p. 180.) to expreſs that claſs of organic remains or reliquia, which ſtick in the ſurface of the matrix or ſeat. The extraneous foſſils of veins are frequently found in this ſtate.

INHERITABLE BLOOD, in *Law*. See BLOOD.

INHERITANCE, HÆREDITAS, a property in lands and tenements to a man and his heirs. See ESTATE, in *Law*.

Inheritance is not only underſtood where a man hath inheritance of lands and tenements by deſcent or heritage; but every fee-ſimple or fee-tail, that a man hath by his purchaſe, may be ſaid to be an inheritance, becauſe his heirs may inherit it after him. (See FEE-*ſimple* and FEE-*tail*.) The inheritances mentioned in our law are either corporeal or incorporeal; the corporeal relate to houſes, lands, &c. that may be touched or handled; and the incorporeal are rights iſſuing out of, annexed to, or exerciſed with corporeal inheritances; as advowſons, tithes, annuities, offices, commons, franchiſes, &c. (See HEREDITAMENTS.) There is likewiſe another inheritance denominated ſeveral, that is, where two or more hold lands ſeverally; as when two perſons hold to them and the heirs of their two bodies, in which caſe theſe two have joint-eſtate during their lives, but their heirs have ſeveral inheritances. Goods and chattels cannot be turned into an inheritance. For the rules of inheritance, ſee DESCENT, *collateral*.

INHIBITION, a writ to inhibit or forbid a judge from farther proceeding in a cauſe depending before him.

Sometimes prohibition and inhibition are put together, as of the ſame import; but inhibition is moſt commonly a writ iſſuing out of a higher court-chriſtian to a lower; and prohibition out of the king's court to an inferior court.

INHIBITION, in *Scots Law*, is a perſonal prohibition, which paſſes by letters under the ſignet, prohibiting the party inhibited to contract any debt, or do any deed, by which any part of his lands may be aliened or carried off in prejudice of the creditor inhibiting. It muſt be executed againſt the debtor, perſonally, or at his dwelling-houſe, as ſummonſes, and afterwards publiſhed and regiſtered in the ſame manner with interdictions. Inhibition may proceed either upon a liquid obligation, or even as an action commenced by a creditor for making good a claim not yet ſuſtained by the judge; which laſt is called "inhibition upon a depending action." Although inhibitions, by their uniform ſtyle, diſable the debtor from ſelling his moveable as well as his heritable eſtate, their effect has been long limited to heritage, from the interruption that ſuch an embargo upon moveables muſt have given to commerce; ſo that debts, contracted after inhibition, may be the foundation of diligence againſt the debtor's perſon and moveable eſtate. An inhibition ſecures the inhibitor againſt the alienation, not only of lands that belonged to his debtor, when he was inhibited, but of thoſe which he ſhall afterwards acquire; but no inhibition can extend to ſuch after-purchaſes as lie in a juriſdiction where the inhibition was not regiſtered; for it could not have extended to thoſe though they had been made prior to the inhibition. An inhibition is ſimply prohibitory; ſo that the debt on which it proceeds, continues perſonal after the diligence. The heir of the perſon inhibited is not reſtrained from alienation by the diligence uſed againſt his anceſtor, for the prohibition is perſonal, affecting only the debtor againſt whom the diligence is uſed. Inhibitions do not of themſelves make void the poſterior debts or deeds of the perſon prohibited. When payment is made by the debtor to the inhibitor, the inhibition is ſaid to be "purged."

INHOC, or Inhoke, in our *Old Writers*, is uſed for any corner or part of a common field ploughed up and ſowed with oats, &c. and ſometimes fenced in with a dry hedge in that year wherein the reſt of the ſame field lies fallow and common. It is called in the North of England an *intock*, and in Oxfordſhire a *hitchin*. And no ſuch *inhoke* is now made without the joint conſent of all the commoners, who in moſt places have their ſhare by lot in the benefit of it, except in ſome manors where the lord has a ſpecial privilege in ſo doing. Kennet's Paroch. Antiq. 297, &c. and his Gloſſary.

The word is Saxon, compounded of *in*, *within*, and *hoke*, *a corner*.

INHUMATION. See Burial and Interment.

Inhumation, in *Chemiſtry*, a method of digeſting ſubſtances together, by burying the veſſel in which they are put in horſe-dung, or in dry ſandy earth expoſed to the ſun. See Digestion.

INIA, in *Geography*, a river of Ruſſia, which runs into the Oby, 50 miles N.E. of Kolivan.—Alſo, a river of Ruſſia, which runs into the Lena, N. lat. 55° 20′. E. long. 116° 14′.

INJAMBI, or Tiete, a river of Brazil, which runs into the Parana, 180 miles N.W. of St. Paul, on the borders of Paraguay.

INIARA, a town of Ruſſia, in the government of Penza; 48 miles W. of Penza.

INJECTION, in *Anatomy*, is the art of filling the blood-veſſels or other hollow organs of the dead body with various ſubſtances, for the purpoſe of inveſtigating their ſtructure, ſituation, &c. or for diſplaying any facts connected with theſe ſubjects by ſubſequent artificial preparation. See Preparations, *Anatomical*.

Injection, in *Pharmacy*, any liquid medicine made to be injected or thrown into the body, or any of its parts, by a ſyringe, clyſter-pipe, or other inſtrument.

Injection, or *Injecting*, in *Surgery*, the throwing in ſome liquor or medicine into a vein opened by inciſion. This practice, and that of transfuſion, or the conveying the arterial blood of one man, or other animal, into another, were once greatly practiſed, but are now laid aſide.

The method of injecting is this: a vein is to be opened in the arm with a lancet as in bleeding, and a ſmall pipe of a ſyringe being introduced at the orifice, the liquor intended to be mixed with the blood, and contained for that purpoſe in the body of the ſyringe is to be forcibly injected, or thrown into the vein upwards, or toward the heart; which done, the orifice is to be ſecured with compreſſes and bandages as in bleeding.

Whether this practice of injecting proper medicines into the blood may not be found of uſe in apoplexies, quinſies, hydrophobia, &c. is worthy to be tried by repeated experiments. The method of injecting liquors into the blood of living animals, is ſaid to be the invention of ſir Chriſtopher Wren. His method was by making ligatures on the veins, and opening them on the ſide of the ligature towards the heart: then putting into them ſmall ſyringes or quills faſtened to bladders in the manner of clyſter-pipes, containing the matter to be injected. Mr. Boyle ſoon made the experiment upon dogs, with infuſions of opium and crocus metallorum; all which he circumſtantially deſcribed, in his Uſefulneſs of Experimental Philoſophy, part ii. eſſ. 2. Phil. Tranſ. N° 7. p. 128.

The ingenious Dr. Hales made a variety of experiments of this kind on different animals. See his Statical Eſſays, vol. ii. paſſim.

Many diſorders of particular parts are no way curable, unleſs the parts affected are injected with a proper liquor by means of a ſyringe and proper tube. The method of performing this is too obvious to need any directions; but theſe general cautions are neceſſary in regard to it, that the ſyringe or tube be applied tenderly and carefully to the parts, eſpecially in very ſenſible or nervous parts, to avoid giving the patient any pain; and that the liquor to be injected be neither too hot nor too cold.

In ulcerations and inflammations of the uvula, tonſils, and fauces, injections are generally uſeful: but care muſt be taken to preſs down the tongue with a ſpatula, or with the flat end of a ſpoon, and having introduced the ſyringe two or three fingers breadth into the mouth, the injection is to be carefully and gently thrown in at ſeveral times. In gonorrhœas, injections are often neceſſary to allay the heat and ſoreneſs of the urethra, and to waſh out the matter. The ſafeſt and beſt injections on this occaſion are warm milk and barley-water, ſweetened with ſugar, honey, or ſyrup of marſhmallows; and towards the end a little ſaccharum ſaturni, diſſolved in plantane water.

INJELLEE, in *Geography*, a province of Bengal, on the right ſide of the Hoogly, near its mouth.

INIO, a ſmall iſland in the Baltic, near the coaſt of Finland, with a town. N. lat. 60° 26′. E. long. 21° 14′.

INIS, a word in the Iriſh language ſignifying *iſland*; and therefore uſed as a prefix to the names of many iſlands on the coaſt of Ireland, ſome of which are noticed in ſucceeding articles, but a much greater number paſſed by as too inſignificant.

INISBEG, in *Geography*, the name of ſeveral ſmall iſlands on the coaſt of Ireland, the name ſignifying *Little Iſland*. One of theſe is in a ſmall bay of the county of Cork, near the town of Skibbereen; another is on the weſt coaſt of Kerry, near the Great Blaſket iſland; and a third is on the north coaſt of the county of Donegal, about 6 miles N.E. of Bloody Farland Point.

INIS-BOFFIN, or Ennisboffin *i. e.* the iſland of the *White Cow*, an iſland near the weſt coaſt of Ireland, containing 1200 acres. It is about a mile and a half from the main land of the county of Galway, and is a pariſh in the dioceſe of Tuam. There was formerly an abbey here. There is an iſland of the ſame name on the coaſt of Donegal, about four or five miles E. by N. of Bloody Farland Point; and a third in Lough Ree, an expanſion of the river Shannon, in which was an abbey that the Danes plundered and deſtroyed in 1089. Beaufort, Carliſle.

INISCALTRA, or Iniscalthra, an iſland ſituated in the river Shannon, belonging to the county of Galway, about two miles S. from mount Shannon, and eight N. by W. from Killaloe. In this beautiful iſland are a fine anchoret tower, above ſeventy feet high, and the remains of ſeven ſmall churches.

INISCATTERY, or Iniscathrie, an iſland belonging to the county of Clare, province of Munſter, Ireland. This rich and beautiful little iſland is ſituated at the entrance of the river Shannon, between the counties of Kerry and Clare, two miles S. by W. from Kilruſh, and nearly oppoſite to the caſtle of Canrigfoile, which was beſieged and taken by ſir W. St. Leger in 1580. According to Mr. Archdall, a monaſtery was founded in Iniſcattery, of which St. Senan was the firſt abbot. There were eleven churches for the monks, and no women were permitted to land on the iſland before the coming of the Danes into Ireland. In proceſs of time it became a priory of regular canons. The monument of St. Senan is ſtill to be ſeen here, with the remains of eleven ſmall churches and ſeveral cells: in the ſtone that encloſes the top of the altar window of the great church is the head of the ſaint with his mitre, boldly executed, and but little defaced. An ancient round tower of 120 feet in height, and in complete repair, graces the ſcene. This iſland is remarkable for the reſort of pilgrims on certain feſtivals. Archdall, Carliſle.

INISDRISUL, or Inisdriscol, an iſland belonging to the county of Cork, province of Munſter, Ireland, ſituated in *Roaring Water Bay*, a little north of Cape Clear iſland.

INISDUFF, or Innisduh, a ſmall iſland off the coaſt of Donegal, in the province of Ulſter, Ireland, about ſix miles N.E. from Bloody Farland Point. Carliſle.

INISFREE, the name of two iſlands off the weſt coaſt of the county of Donegal, province of Ulſter, Ireland; one of which is in the cluſter of the North Arran iſles, a little ſouth of Rutland; the other, which gives name to a ſmall harbour, lies between Rutland and Bloody Farland Point. M'Kenzie, Beaufort.

INISGLORA, a ſmall uninhabited iſland off the weſt coaſt of Mayo, in the province of Connaught, Ireland.

INISGOULA, an iſland in Clew bay, county of Mayo, province of Connaught, Ireland, on the eaſt ſide of which is good anchorage for large veſſels. Mackenzie.

INISHARK Island, an iſland near the weſt coaſt of Ireland and county of Galway. N. lat. 53° 34′. W. long. 10° 14′.

INISHEGIL, or, according to Mackenzie, *Iniſhegil*, an iſland off the coaſt of Mayo, Ireland, between Achill iſland and the main land.

INISHERKAN, an iſland near the ſouth coaſt of Ireland, belonging to the county of Cork, on the weſt ſide of Baltimore harbour. N. lat. 51° 24′. W. long. 9° 19′.

INISHONAN, or Inishannon, a poſt-town of Ireland, in the county of Cork, and province of Munſter. It is on the Bandon river, ten miles from Cork, three from Bandon, and 133 S.W. from Dublin.

INISHOWEN, a large peninſula and barony of the county of Donegal, Ireland, which ſtretches N.E. from Londonderry, bounding Lough Foyle. It is a dreary mountainous region, but great exertions have been made to meliorate its natural rudeneſs. It indeed returns a greater rent than any other part of the county. The mountains feed a number of cattle, and the flats produce tolerable crops. They have manure of the beſt quality in abundance, ſuch as limeſtone, ſhells, and ſea-ware, which act powerfully upon the barrenneſs of the ſoil. Robertſon.

Inishowen *Head*, a cape in Ireland, forming the eaſtern extremity of the peninſula, a little north of the entrance into Lough Foyle. N. lat. 55° 15′. E. long. 6° 48′.

INISKEA, the name of two ſmall iſlands off the weſt coaſt of Ireland, between which there is good anchorage. They are about two miles from the peninſula of the Mullet, in the county of Mayo; between 54° 7′, and 54° 10′ N. lat. and 10° W. long.

INISLIRE, an iſland in Newport or Clew bay, county of Mayo, Ireland, which gives name to one of the beſt ſtations for veſſels in that extenſive bay. Mackenzie.

INISMURRY, Inismurra, or *Innis-muidhr*, an iſland which lies off the coaſt of Sligo, Ireland, about three miles diſtant from the main land. It contains 130 acres, two wells of excellent water, and ſome bog of remarkably good turf. The inhabitants are few, and live by fiſhing. There are the remains of ſome chapels within a ſtone wall ten feet high, and from five to ſeven and eight feet thick, without cement. Mr. Archdall ſays it is impoſſible to determine whether it is round or oval; and that more rude, inelegant workmanſhip was never ſeen. There are a few cells under ground, which receive their light, ſome through a hole at the top, others through a loop-hole in the ſide; they are dark and horrible dungeons. Gen. Vallancey infers from part of theſe ruins, that in Pagan times, the iſland was dedicated to the worſhip of Boodha, and ſays that a monument in this iſland is an exact repreſentation of the Mahoody of the Gentoos found in the iſland of Elephanta, near Bombay, by captain Pyke. Many devotees ſtill flock to this iſland to do penance in the cells, and many are brought from great diſtances to be buried in the churches. There is a ledge of rocks running from this iſland, which require the attention of all who enter the bay of Sligo. Vallancey's Proſpectus of a Dictionary; Carliſle.

INISTIOGE, a ſmall poſt-town of Ireland, in the county of Kilkenny, and province of Leinſter. It is ſituated on the river Nore, which is navigable to it, and over which it has a bridge with ten arches. Iniſtioge is one of theſe places which before the Union ſent two members to the houſe of commons of Ireland. It is 63 miles S.W. from Dublin.

INISTUISKAR, an iſland off the weſt coaſt of the county of Kerry, Ireland, about four miles from Caunſza head, and north of the Blaſquets. N. lat. 52° 8′. W. long. 10° 25′.

INISTURC, an iſland ſituated about ſeven miles from the weſt coaſt of Mayo, Ireland, not far from the Killeries. N. lat. 53° 42′. W. long. 10°.

INITIALIA, a name anciently given to the myſteries of Ceres. See Cerealia.

INITIALIS *et pauſa generalis*, the beginning of a muſical compoſition, and the end. See Tempo, Prolation, and Pause.

INITIANS Punctum. See Punctum.

INITIATE, *Tenant by Curteſy*, in *Law*. See Tenant.

INITIATED, a term properly uſed in ſpeaking of the religion of the ancient heathens; where it ſignifies being admitted to the participation of the ſacred myſteries.

The word comes from the Latin *initiatus*, of *initiare*, *initiari*; which properly ſignifies to begin ſacrificing, or to receive or admit a perſon to the beginning of the myſteries; or of ceremonies of leſs importance.

The ancients never diſcovered the deeper myſteries of their religion, nor even permitted ſome of their temples to be opened to any but thoſe who had been initiated. See Mystery.

INJUNCTION, in *Law*, a writ generally grounded upon an interlocutory order or decree out of the court of chancery or exchequer, ſometimes to give poſſeſſion to the plaintiff, for want of the defendant's appearance; ſometimes to the king's ordinary court, and ſometimes to the court-chriſtian, to ſtop proceedings in a cauſe, upon ſuggeſtion made, that the rigour of the law, if it take place, is againſt equity and conſcience in that caſe, that the complainant is not able to make his defence in theſe courts for want of witneſſes, &c. or that they act erroneouſly denying him ſome juſt advantage. The writ of injunction is directed not only to the party himſelf, but to all and ſingular his counſellors, attornies, and ſolicitors; and if any attorney, after having been ſerved with an injunction, proceeds afterward contrary to it, the court of chancery will commit the attorney to the fleet for contempt. But if an injunction be granted by the court of chancery in a criminal matter, the court of king's bench may break it, and protect any that proceed in contempt of it.

INJURY, Injuria, in a general ſenſe, ſignifies any thing contrary to juſtice and equity; that is, any wrong or damage done to a man's perſon, reputation, or goods.

The word is derived from the Latin prepoſition *in*, which here has a negative power; and *jus, law, right: injuria, dicitur omne quod non jure fit.* The ancients made a goddeſs of injury, and called her Ate. Homer makes her the daughter of Jupiter, and ſays ſhe did miſchief to every body, even to her father; that ſhe was very nimble and tender-footed, and walked altogether on men's heads without ever touching the ground.

Civilians define injury a private offence, committed deſignedly, and with an evil intention to any man's prejudice, with regard to his perſon or his property. All civil injuries are of two kinds; the one without force or violence, as ſlander or breach of contract; the other joined with force and violence, as batteries and falſe impriſonment. The author of the Rhetorics to Herennius ſays, "Injuria eſt quæ aut pulſatione, aut convitio, aut turpitudine, corpus, aures, aut vitam alicujus violavit."

By the Roman law, the action for an injury was annual: that is, no reparation could be required after the expiration of a year. By the law of the twelve tables, where the injury was the breaking of a limb, the injured perſon might demand talionem, that is, that he might break the ſame limb of the criminal.

For the breaking of a bone there were alſo conſiderable pecuniary puniſhments aſſigned: for other injuries only twenty aſſes were decreed, which the poverty of thoſe times thought a ſufficient penalty; but the prætors afterwards finding this too ſlender a ſatisfaction, in lieu thereof, appointed the injured perſon to ſet a rate on the injury, which they afterwards increaſed or leſſened as they thought good.

Some of our lawyers make a diſtinction between a *damage* and an injury; and indeed there are many acts which may be done to the prejudice of a third perſon, which may be properly ſaid to be *damnum ſine injuria.*

As the abſolute rights of individuals are thoſe of perſonal ſecurity, perſonal liberty, and private property, the wrongs or injuries affecting them muſt conſequently be of a correſponding nature. Injuries that affect the perſonal ſecurity of individuals are injuries againſt their lives, their limbs, their bodies, their health, or their reputation. For the firſt claſs of injuries, ſee Homicide, Manslaughter, and Murder. The two next ſpecies of injuries, affecting the limbs or bodies of individuals, may be committed by *threats, aſſault, battery, wounding, mayhem,* which ſee reſpectively. For the four laſt injuries now enumerated, an indictment may be brought as well as an action; and frequently both are accordingly proſecuted, the one at the ſuit of the crown for the crime againſt the public; the other at the ſuit of the party injured, to make him a reparation in damages. Injuries affecting a man's health are thoſe by which any unwholeſome practices of another cauſe a man to ſuſtain any apparent danger in his vigour or conſtitution: as by ſelling him bad proviſions, as wine (1 Roll. Abr. 90.); by the exerciſe of a noiſome trade, which affects the air in the neighbourhood (9 Rep. 52. Hutt. 135.); or by the neglect or unſkilful management of his phyſician, ſurgeon, or apothecary. (Lord Raym. 214.) For theſe injuries, unaccompanied by force, there is a remedy in damages, by a ſpecial action of *treſpaſs upon the caſe.* Injuries affecting a man's reputation, or good name, are, firſt, by malicious, ſcandalous, and ſlanderous words, tending to his damage and derogation. (See Words and Scandalum *Magnatum;* and Action *upon the caſe.*) A ſecond way of affecting a man's reputation is by printed or written libels, pictures, ſigns, and the like; which ſet him in an odious or ridiculous light, and thereby diminiſh his reputation. (2 Shaw. 314. 11 Mod. 99.) See Libel. A third way of deſtroying or injuring a man's reputation is by preferring malicious indictments or proſecutions againſt him; which, under the maſk of juſtice and public ſpirit, are ſometimes made the engines of private ſpite or enmity. For this, however, the law has given a very adequate remedy in damages, either by an action of conſpiracy (Finch. L. 305.), which cannot be brought but againſt two at the leaſt; or, which is the more uſual way, by a ſpecial action on the caſe for a falſe and malicious proſecution. (F. N. B. 116.) The violation of the right of perſonal liberty is effected by the injury of falſe impriſonment, for which the law has not only decreed a puniſhment, as a heinous public crime, but has alſo given a private reparation to the party; as well by removing the actual confinement for the preſent, as, after it is over, by ſubjecting the wrong doer to a civil action, on account of the damage ſuſtained by the loſs of time and liberty. (See Imprisonment, and False *Impriſonment.*) The injuries that affect the rights of perſonal property, affect it either as it is in poſſeſſion or in action. (See Property.) The former kind of property is liable to two ſpecies of injuries, *viz.* the amotion or deprivation of that poſſeſſion, and the abuſe or damage of the chattels, while the poſſeſſion continues in the legal owner. The deprivation of poſſeſſion comprehends the unjuſt and unlawful taking away, and the unjuſt detention, though the original taking might be lawful. The remedy which the law has provided for the wrongful taking of goods, is the reſtitution of them, with damages for the loſs ſuſtained by ſuch unjuſt invaſion, which is effected by action of "replevin," which ſee. Other remedies for other unlawful taking of a man's goods conſiſt only in recovering a ſatisfaction in damages, by an action of *treſpaſs vi et armis,* or action of *trover* and *converſion,* which ſee reſpectively. For unjuſt detention of another's goods, when the original taking was unlawful, the remedy for the recovery of poſſeſſion is by action of *detinue;* or action of *trover,* which ſee. The remedies given by the law to redreſs damages, which the things detained may have ſuffered, are action of *treſpaſs vi et armis,* where the act is in itſelf immediately injurious to another's property, and accompanied with ſome degree of force; and ſpecial *action on the caſe,* where the act itſelf is indifferent, and the injury only conſequential, and therefore ariſing without any breach of the peace. As to injuries that regard things in *action* only, they pertain to ſuch rights as are founded on, and ariſe from contracts, which may be either *expreſs* or *implied*. The former are *debts*, *covenants*, and *promiſes*; ſee each term: the latter are ſuch as reaſon and juſtice dictate, and which the law preſumes that every man has contracted to perform. Thus it is that every perſon is bound, and hath virtually agreed to pay ſuch particular ſums of money as are charged upon him by the ſentence, or aſſeſſed by the interpretation of the law. A debt is thus contracted, and the defendant is bound to pay it. The ſame reaſoning will apply to all penal ſtatutes, that is, ſuch acts of parliament by which a forfeiture is inflicted for tranſgreſſing the proviſions therein enacted. The party offending muſt pay the forfeiture incurred to ſuch perſons as the law requires. Another claſs of contracts includes thoſe which ariſe from natural reaſon, or the juſt conſtruction of law. (See ASSUMPSIT.) The laſt claſs of contracts, implied by reaſon and conſtruction of law, ariſes upon this ſuppoſition, that every one who undertakes any office or employment, truſt or duty, contracts with thoſe who employ or truſt him, to perform it with integrity, diligence, and ſkill; and if for want of theſe qualities any injury accrues to individuals, they have their remedy in damages by a ſpecial action on the caſe.

Beſides the ſpecial action on the caſe, there is alſo a peculiar remedy, entitled an action of *deceit*, (F. N. B. 95.) to give damages in ſome particular caſes of fraud, and principally where one man does any thing in the name of another, by which he is deceived or injured.

As to thoſe injuries that affect men with regard to their *relative* rights, they may be done to perſons under the four following relations: huſband and wife, parent and child, guardian and ward, maſter and ſervant; and they comprehend in the relation of a huſband, *abduction*, *adultery*, and *beating* or otherwiſe abuſing the wife. In the relation of a parent, the injury is *abduction*, which is remedied by a writ of *raviſhment*, or action of *treſpaſs vi et armis*, *de filio* vel *filia*, *rapto vel abducto*. (F. N. B. 90.) See the other terms above ſpecified.

Having briefly recited the principal injuries that may be offered to *perſonal* property, with their ſeveral remedies by ſuit or action, we ſhall next direct our attention to thoſe injuries which affect that ſpecies of property which the laws of England have denominated *real*. Real injuries, or injuries affecting real rights, are principally the following ſix; *ouſter*, *treſpaſs*, *nuſance*, *waſte*, *ſubtraction*, and *diſturbance*; which ſee reſpectively. Blackſt. Com. b. iii.

INJURIES *of the Head*. Some ſubjects, connected with this highly intereſting part of *ſurgery*, have already been treated of in the preceding volumes of this Cyclopædia. See COMPRESSION; CONCUSSION; and EXTRAVASATION. Here it is incumbent upon us to conſider certain other caſes, which are the conſequence of external violence applied to the head, as wounds and contuſions of the ſcalp; inflammation of the dura mater, and ſuppuration under the cranium; fractures of the ſkull, &c.

Injuries of the Scalp.—Injuries done to the ſcalp by external violence are generally of a more ſerious nature than a ſimilar degree of miſchief done to any other part of the common integuments. Surgical authors have endeavoured to account for this fact by adverting to the prodigious quantity of nervous filaments diſtributed to the ſcalp, the many different parts which compoſe it, its ſtructure, connections, &c. We are not, however, to ſuppoſe every injury of the external coverings of the head dangerous. A mere cut with a ſharp inſtrument uſually heals as favourably in this ſituation as in any other, and often more ſo, perhaps, in conſequence of the great vaſcularity of the ſkin of the head, and the very ſteady manner in which the edges of the wound admit of being kept in contact, ſupported as they are upon the fixed ſurface of the cranium. But punctures, lacerated wounds, and contuſions of the ſcalp, as every experienced ſurgeon well knows, are caſes frequently followed by ſuch ſymptoms as may terminate fatally.

We ſhall paſs over inciſed wounds of the ſcalp, ſince they are attended with no peculiarity, and only require the ſame treatment as ordinary cuts upon any part of the ſurface of the body.

Lacerated wounds of the ſcalp are divided by Mr. Pott into two kinds; *viz.* thoſe in which the ſcalp, though torn, or unequally divided, ſtill keeps its natural ſituation, and is not ſtripped nor ſeparated from the cranium to any conſiderable diſtance beyond the breadth of the wound; and thoſe, in which it is conſiderably detached from the parts it ought to cover.

The firſt of theſe, if ſimple, and not combined with the ſymptoms, or appearances of any other miſchief, do not require any particular or different treatment from what the ſame kind of wounds require on all other parts; but the latter, or thoſe in which the ſcalp is ſeparated and detached from the parts it ought to cover, are not only, by the different methods in which they may be treated, frequently capable of being cured with a conſiderable deal more or leſs eaſe and expedition, but are alſo ſometimes a matter of great conſequence to the health and well-being of the patient.

Not many years ago ſurgeons were accuſtomed to treat this laſt ſort of caſe in a moſt objectionable way. Too haſtily convinced of the impoſſibility of the ſeparated and torn pieces of the ſcalp ever becoming united again, practitioners uſed, without heſitation, to cut them away, ſo as to occaſion a large ſore, requiring a long time to heal, and leaving conſiderable deformity. Far different is the practice of the moſt approved modern ſurgeons, with whom it is an invariable maxim, that the preſervation of the ſcalp ought always to be attempted. The reaſons for this line of conduct are plain and obvious. The detached portions of the ſcalp were formerly cut off, becauſe it was ſuppoſed that they were in ſuch a ſtate as precluded all chance of their union. But the fact is, it can never be foreſeen with certainty whether the detached torn edges of a lacerated wound will ſlough or not. Now, as no harm can ariſe from trying whether they will live and unite; as conſiderable benefit will reſult from the ſucceſs of ſuch an attempt; and, as the exciſion of the part is painful, and productive of no ſolid advantage, even when ſloughing is unavoidable, the method is ſupported neither by reaſon nor experience. Whatever may be the courſe of the caſe, the proceeding is only calculated to cauſe unneceſſary pain, lengthen the time required for the cure, and render deformity, which is uncertain, quite inevitable. The head having been ſhaven round the wound, the torn piece of the ſcalp is to be firſt freed from all dirt and extraneous ſubſtances, and then reſtored as quickly and as perfectly as poſſible to its natural ſituation. Strips of adheſive plaſter fully ſuffice for bringing the parts together without the aſſiſtance of ſutures, which, unleſs abſolutely neceſſary, ought never to be uſed. It has always appeared to us a very beneficial plan to maintain the pieces of the ſcalp cloſely applied to the cranium by means of ſmall lint-compreſſes, bound on with adheſive plaſter. Thus, no cavity will be left for the lodgment of matter, and the parts will have the faireſt opportunity of uniting. Sometimes the looſened ſcalp will unite with the parts from which it was torn and ſeparated, and there will be no other ſore than what ariſes from the impoſſibility of bringing the lips of the wound into ſmooth and immediate contact, the ſcar of which ſore muſt be ſmall in proportion. Sometimes ſuch perfect re-union is not to be obtained; in which caſe matter will be formed and collected in thoſe places where the parts do not coaleſce; but this will not hinder the preſervation of the coverings of the head, the cure being only a little retarded by a few ſmall abſceſſes, and the matter admitting of being let out by one or two ſmall openings.

Occaſionally, the whole ſeparated piece will unite perfectly, eſpecially in young and healthy perſons. In certain inſtances the union will take place in ſome parts, and not in others; and, conſequently, matter will be formed, and require to be diſcharged, perhaps, at ſeveral different points. In other particular caſes, circumſtances, and habits, there will be no union at all, the torn cellular membrane, or the naked aponeuroſis will inflame and become ſloughy, a conſiderable quantity of matter will be collected, and, perhaps, the cranium will be denuded. But even in this caſe, if the ſurgeon takes proper meaſures, and refrains from being too much in a hurry to cut, things will be more proſperous than may be expected. Let him take care to keep the inflammation under by proper means; let him have patience till the matter is fairly and fully formed, and the ſloughs perfectly ſeparated; and when this is accompliſhed, let him make a proper number of dependent openings; and let him, by bandage and other proper management, keep the parts in conſtant contact with each other, and he will often find, that, although he was foiled in his firſt intention of procuring immediate union, yet he will frequently ſucceed in this his ſecond; he will ſtill ſave the ſcalp, ſhorten the cure, and prevent the great deformity ariſing, particularly to women, not only from the ſcar, but from the total loſs of hair.

Many perſons have erroneouſly thought, that, when the pericranium is ſtripped off the cranium by external violence, or is afterwards caſt off, the ſcalp cannot unite to the denuded cranium, which muſt of neceſſity exfoliate. However, theſe notions are now well known to be unfounded. The expoſed part of the ſkull, unleſs much injured by contuſion, or improperly irritated by ſtimulating applications, will generally live, throw out granulations, and become united to the ſeparated ſcalp, without any exfoliation whatever.

Punctured wounds of the ſcalp are more apt than cuts to inflame and give trouble, and are indeed frequently the cauſe of ſevere and alarming ſymptoms.

According to Mr. Pott, if the wound affects the cellular membrane only, and has not reached the aponeuroſis, or pericranium, the inflammation and tumour affect the whole head and face, the ſkin of which wears a yellowiſh caſt, and is ſometimes thick ſet with ſmall bliſters, containing the ſame coloured ſerum; it receives the impreſſion of the fingers, and becomes pale for a moment, but returns immediately to its inflamed colour; it is not very painful to the touch, and the eye-lids and ears are always comprehended in the tumefaction, the former of which are ſometimes ſo diſtended as to be cloſed; a feveriſh heat and thirſt generally accompany it; the patient is reſtleſs, has a quick pulſe, and moſt commonly a nauſea and inclination to vomit.

Caſes are moſt diſpoſed to aſſume this form in perſons of bilious habit, the inflammation being in fact eryſipelatous. The diſorder is ſomewhat alarming to look at, but it is not often attended with danger. Mr. Pott remarks, that the wound does, indeed, neither look well, nor yield a kindly diſcharge, while the fever continues; but ſtill it has none of that look which beſpeaks internal miſchief; the ſcalp continues to adhere firmly to the ſkull; nor does the patient ſuffer the tenſive pain, and fatiguing reſtleſſneſs, which generally attend miſchief underneath the ſkull.

Such eryſipelatous inflammation commonly ſoon yields to phlebotomy, lenient purges, and febrifuge medicines, particularly thoſe of the neutral kind. When the inflammation is gone off, it leaves on the ſkin a yellowiſh tint, and a dry ſcurf, which alſo, in time, diſappear. Immediately the diſorder ſubſides, the wound puts on a healthy aſpect, and heals without trouble.

Surgeons muſt carefully diſtinguiſh from the foregoing caſe another kind of eryſipelatous ſwelling and inflammation to which the ſcalp is liable, as one of the effects of inflammation and ſuppuration of the dura mater. In this laſt important diſorder the febrile ſymptoms are much higher, the pulſe harder and more frequent, the anxiety and reſtleſſneſs extremely fatiguing, the pain in the head intenſe; and as, in theſe circumſtances, the ſwelling of the ſcalp is moſt frequently the immediate precurſor of matter forming between the ſkull and dura mater, it is generally attended with irregular ſhiverings, which are not followed by a critical ſweat, nor afford any relief to the patient. When the inflammation is confined to the parts on the outſide of the ſkull, the eryſipelas generally appears within the firſt three or four days; but when the dura mater is affected, it ſeldom comes on till ſeveral days after the accident, when the ſymptomatic fever is got to ſome height. In the ſimple eryſipelas, although the wound be crude and undigeſted, yet it has no other mark of miſchief; the pericranium adheres firmly to the ſkull, and, upon the ceſſation of the fever, all appearances become immediately favourable. In that which accompanies injury done to the parts underneath, the wound not only has a ſpongy, glaſſy, unhealthy aſpect, but the pericranium in its neighbourhood ſeparates ſpontaneouſly from the bone, and quits all coheſion with it. In ſhort, ſays Mr. Pott, one is an accident proceeding from a bilious habit, and not indicating any miſchief beyond itſelf; the other is a ſymptom, or a part of a diſeaſe, which is occaſioned by injury done to the membranes of the brain; one portends little or no ill to the patient, and almoſt always ends well; the other implies great hazard, and moſt commonly ends fatally.

When the wound is ſmall, and reaches to the aponeuroſis and pericranium, diſagreeable, and even alarming ſymptoms ſometimes ariſe. In the caſe alluded to, the inflamed ſcalp does not riſe into that degree of tumefaction as in the eryſipelas; neither does it pit, or retain the impreſſion of the fingers of an examiner. It is of a deep red colour, unmixed with the yellow tint of the eryſipelas; it appears tenſe, and is extremely painful to the touch. The ears and eye-lids are ſeldom comprehended in the tumour, though they may partake of the general inflammation of the ſkin. It is generally attended with acute pain in the head, and ſuch a degree of fever as prevents ſleep, and ſometimes brings on delirium. A patient, thus affected, may be more freely bled than one labouring under an eryſipelas. Warm fomentations are proper in both caſes; but emollient poultices, which are forbidden in eryſipelatous diſeaſes, may be employed in the preſent inſtance with much advantage.

In exceedingly urgent caſes, Pott recommends making a diviſion of the wounded part down to the bone, to the extent of half an inch, or an inch, as the beſt means of ſtopping the fever, and preventing the aponeuroſis and pericranium from becoming ſloughy.

Mere *contuſions of the ſcalp*, unattended by fracture, or injury of the parts within the cranium, are not of ſerious importance, conſidered abſtractedly. It frequently happens, that when a ſevere bruiſe has been inflicted on the ſcalp, a large tumour, containing extravaſated blood, quickly riſes upon the head, or blows on this part with ſtones, ſticks, &c. But, notwithſtanding the immenſe disfigurement attending this ſort of accident, if the ſkull and its contents be free from injury, the caſe is not of a dangerous nature. The effuſed blood generally admits of being removed by abſorption, provided the ſurgeon is careful to keep the patient's bowels well open with ſaline purges, and apply to the tumour itſelf linen wet with the ſaturnine lotion, or with a lotion compoſed of ſpirit of wine, vinegar, and the muriate of ammonia. Many ſurgical authors countenance the plan of diſcharging the collection of blood by a ſmall puncture. As far as our obſervations extend, this practice ſhould be avoided in the generality of inſtances. When an opening is made, ſuppuration within the ſwelling becomes inevitable. On the contrary, abſceſſes may frequently be prevented altogether, by allowing the abſorbents to do the office of taking away the effuſed blood, aſſiſted by the means already recommended. It is not to be denied, however, that matter will ſometimes form, and then the method of making an opening for the diſcharge of the contents of the ſwelling is undoubtedly proper.

With regard to thoſe tumours of the ſcalp, which are the conſequence of blows, falls, &c. and which are filled with effuſed blood, J. L. Petit made a remark, which has been repeated by all ſubſequent writers, namely, the facility with which the centre of the ſwelling may be depreſſed, while the circumference ſeems hard and prominent, circumſtances which may eaſily impoſe upon the inexperienced ſurgeon, and lead him to miſtake the caſe for a fracture of the cranium with depreſſion of the bone. If, upon ſuch a ſuppoſition, he immediately makes an inciſion into the tumid ſcalp, he may give the patient a great deal of unneceſſary pain, and endanger his own reputation.

It is obſerved by Mr. Pott, that in this caſe the touch is ſo liable to deception, that recourſe ſhould always be had to other circumſtances and ſymptoms, before an opinion is given. If a perſon, with ſuch tumour occaſioned by a blow, and attended with ſuch appearances and feel, ſeems to labour under dangerous preſſure upon the brain, a diviſion of the ſcalp, in order to enquire into the ſtate of the ſkull, is right and neceſſary; but if the patient is well, or not ſeriouſly affected with any ſymptoms of compreſſion, the mere feel of ſome thing like a fracture, nay, we may add, even the actual exiſtence of a fracture itſelf, will not authoriſe or vindicate cutting the ſcalp.

For an account of the ſymptoms of preſſure on the brain, ſee COMPRESSION and EXTRAVASATION.

Inflammation of the Dura Mater, and Suppuration under the Skull.—The ſymptoms attending an inflamed or ſloughy ſtate of the membranes of the brain, in conſequence of external violence, are all of the febrile kind, and never at firſt imply any unnatural preſſure upon the brain. When, in theſe caſes, the ſymptoms of preſſure come on, it is not until the latter end of the diſeaſe, that is, until a conſiderable quantity of matter is formed, which matter muſt preſs like any other fluid.

The late eminent Mr. Pott has written a moſt able deſcription of the inflammation and ſuppuration of the dura mater from external violence. The following obſervations are chiefly from his pen.

When there is neither fiſſure nor fracture of the ſkull, nor extravaſation, nor commotion underneath it, and the ſcalp is neither conſiderably bruiſed nor wounded, the miſchief is ſeldom diſcovered or attended to for ſome few days. The firſt attack is generally by pain in the part which received the blow. This pain is ſoon extended all over the head, and is attended with a languor or dejection of ſtrength and ſpirits, which are ſoon followed by a nauſea and inclination to vomit, a vertigo or giddineſs, a quick and hard pulſe, and an incapacity of ſleeping. A day or two after this attack, if no means preventive of inflammation are uſed, the part ſtricken generally ſwells, and becomes puffy and tender, but not painful. Neither does the tumour riſe to any conſiderable height, nor ſpread to any great extent. If this tumid part of the ſcalp be now divided, the pericranium will be found of a darkiſh hue, and either quite detached, or very eaſily ſeparable from the ſkull, between which and it will be found a ſmall quantity of a dark-coloured ichor. If the diſorder is ſo advanced, that the pericranium is quite ſeparated from the ſkull, the latter will be found ſomewhat altered in colour from a healthy bone.

From this time the ſymptoms generally advance more haſtily and more apparently; the fever increaſes, the ſkin becomes hotter, the pulſe quicker and harder, the ſleep more diſturbed, the anxiety and reſtleſſneſs more fatiguing; and to theſe, ſays Mr. Pott, are generally added irregular rigours, which are not followed by any critical ſweat, and which, inſtead of relieving the patient, add conſiderably to his ſufferings. If the ſcalp has not been divided, until the ſymptoms are thus far advanced, the alteration of the colour of the bone will be found to be more remarkable; it will be found to be whiter and more dry than a healthy one; or, as Fallopius has obſerved, it will appear rather like dead bone.

There will be more ſanies or fluid under the pericranium, and this membrane will have a more livid aſpect.

In this ſtate of matters, if the dura mater be denuded, it will be found to be detached from the inſide of the cranium, to have loſt its bright ſilver hue, and to be ſmeared over with a kind of mucus or pus. Every hour after this period all the ſymptoms are exaſperated; the head-ache and thirſt become more intenſe, the ſtrength decreaſes, the rigours are more frequent, and, at laſt, convulſive motions, attended in ſome with delirium, in others with paralyſis, or comatoſe ſtupidity, finiſh the tragedy.

If the ſcalp is now divided, a very offenſive diſcoloured fluid will be found lying on the bare and altered cranium. If, at this period, a perforation is made in the bone, matter will be found between it and the dura mater, generally in conſiderable quantity, but different in different caſes and circumſtances. Sometimes it will be in great abundance, and diffuſed over a very large part of the membrane; and ſometimes the quantity will be leſs, and conſequently the ſpace which it occupies ſmaller. Sometimes it lies only on the exterior ſurface of the dura mater; and ſometimes it is between it and the pia mater, or alſo on the ſurface, or in the ſubſtance of the brain.

The foregoing miſchief is entirely the conſequence of the contuſion which the head has ſuffered. But it deſerves attention, that as the inflammation and ſeparation of the dura mater are not *immediate* conſequences of the violence, ſo neither are the ſymptoms immediate, ſeldom coming on until ſome days have paſſed.

We have next to conſider the caſe where the ſcalp has been wounded, either by the accidental violence, or by the ſurgeon making an inciſion immediately afterwards for the examination of the bone. Here the wound will, for ſome little time, have nothing particular about it; but after a few days, any favourable appearances which it may have put on will vaniſh; the ſore will loſe its florid complexion and granulated ſurface; will become pale, glaſſy, and flabby; inſtead of good matter, it will diſcharge only a thin diſcoloured ſanies; the lint with which it is dreſſed, inſtead of coming off eaſily, as in a kindly ſuppurating ſore, will ſtick to all parts of it; and the pericranium

cranium, inſtead of adhering firmly to the bone, will ſeparate from it all round to ſome diſtance from the edges.

This alteration in the face and circumſtances of the ſore is produced merely by the diſeaſed ſtate of the parts underneath the ſkull, as is demonſtrably proved, by obſerving that the bad aſpect of the wound, and the ſpontaneous ſeparation of the pericranium, are always confined to that part which covers the altered or injured portion of the dura mater, and do not at all affect the reſt of the ſcalp; nay, obſerves Mr. Pott, if it has by accident been wounded in any other part, or a portion has been removed from any part where no injury has been done to the dura mater, no ſuch ſeparation will happen. The detachment above will always correſpond to that below, and be found no where elſe.

At firſt the expoſed part of the ſkull appears whiter and more dry than natural, and in proportion as the dura mater ſuppurates or becomes ſloughy, the bone inclines more and more to a kind of purulent hue, or whitiſh yellow. It deſerves notice, likewiſe, that if the blow has occurred near a ſuture, and the ſubject is young, ſuch ſuture often ſeparates ſo as to let through it a looſe painful fungus. At this period alſo the head and face are frequently attacked with eryſipelas.

The above deſcribed effects of certain contuſions of the head are frequently found to accompany fiſſures and undepreſſed fractures of the cranium, as well as extravaſations of fluid, where the bone is entire; and on the other hand, ſays Mr. Pott, all theſe do often happen without the concurrence of this individual miſchief. All this is matter of accident; but let the other circumſtances be what they may, the ſpontaneous ſeparation of the altered pericranium, in conſequence of a ſevere blow, is almoſt always followed by a ſuppuration between the cranium and dura mater; a circumſtance, which Mr. Pott points out as highly worthy of attention in fiſſures and undepreſſed fractures of the ſkull, becauſe it is from this cauſe principally that the bad ſymptoms, and the hazard in ſuch caſes, ariſe.

The ſituation of extravaſated blood within the cranium is often uncertain; but that of inflammation and ſuppuration of the dura mater, in conſequence of external violence, is almoſt ſurely indicated, even when the ſkin is quite free from wound, or other mark of injury, by a puffy, circumſcribed, indolent tumour of the ſcalp, and a ſpontaneous ſeparation of the pericranium from the ſkull under the ſwelling.

It ſhould be underſtood that none of the bad ſymptoms are owing to the ſeceſſion of the pericranium, but to the inflammation of the dura mater. Hence, though the ſcalp may be ſo wounded or torn by any accident, as to leave a part of the ſkull quite bare, the pericranium being ſeparated by the violence, yet if the force has not been ſuch as to affect the dura mater, the alarming train of evils above explained do not follow. Here the beſt practice is to lay down the ſcalp in its natural ſituation again, and give it the opportunity of uniting.

It remains for us to conſider the treatment of the reſpective caſes, where there is either danger of an inflammation of the dura mater coming on, or where the affection actually prevails, attended with the formidable ſymptoms already detailed.

Every man of experience will coincide with Mr. Pott, that of all the remedies in the power of art, for inflammations of membranous parts, there is none equal to phlebotomy, and that if any thing can particularly contribute to the prevention of the ills likely to follow ſevere contuſions of the head, it is this kind of evacuation; but then it muſt be made uſe of in ſuch a manner as to become truly a preventive; that is, it muſt be made uſe of immediately and freely.

There will often be ſome difficulty in perſuading a perſon, who has had what may be called only a knock on the pate, to ſubmit to ſuch diſcipline, eſpecially if he finds himſelf tolerably well: yet, in many inſtances, the timely uſe, or the neglect of this ſingle remedy, makes all the difference between ſafety and fatality. It is true, that by this method patients muſt ſometimes be bled, who would eſcape inflammation of the dura mater without ſuch evacuation; yet, let it be remembered, that the loſs of blood, however unneceſſary in theſe caſes, never endangers life, while it is frequently the means of preſerving it. In ſhort, we muſt agree with Mr. Pott, that if every perſon who meets with a ſevere blow on the head were to be bled, as he undoubtedly ought to be, many a very valuable life would be preſerved, which, for want of this kind of aſſiſtance, is loſt. Acceleration, or hardneſs of pulſe, reſtleſſneſs, anxiety, and any degree of fever, after a ſmart blow on the head, are always to be ſuſpected and attended to. Immediate, plentiful, and repeated evacuations have, in many inſtances, removed theſe complaints in perſons, to whom, Mr. Pott believes, very terrible miſchief would have happened, had not ſuch precaution been uſed. From theſe obſervations, however, let it not be concluded, that early bleeding will always prove a certain preſervative; like all other human means it is fallible; but, if it ſometimes fails, it alſo ſucceeds to a greater extent than any other known plan.

When the inflammation of the dura mater has produced matter under the cranium, the fluid ought to be diſcharged through a perforation of the bone. This operation ought always to be done immediately when the above deſcribed ſymptoms manifeſt the nature of the caſe. The ſpontaneous ſeparation of the dura mater, if attended with general diſorder of the patient, with chillineſs, horripilatio, languor, and fever, was invariably conſidered by Mr. Pott a ſure indication of miſchief underneath, and an urgent reaſon for perforating the bone without delay. In ſome caſes one perforation will ſuffice; in others, more openings muſt be made. This variation will depend upon the ſpace of detached dura mater, and the quantity of matter collected.

The repetition of blood-letting, of cooling laxative medicines, the uſe of antiphlogiſtic remedies, and a moſt ſtrict obſervance of a low diet and regimen, are as indiſpenſably requiſite after trephining as before. The perforation obviates the dangerous effects of the confinement of matter; but it does nothing more; and the inflamed ſtate of the parts under the ſkull ſtill calls for our moſt earneſt attention. See Pott on Injuries of the Head.

Fractures of the Skull.—Whenever the head is ſtricken with a certain degree of violence, the effect is not limited to a vehement concuſſion of this part of the body, or to the bruiſing and wounding of the ſcalp; the bones forming the cranium are alſo liable to be broken. When the weapon, or thing with which the blow is given, preſents an angular or a projecting ſurface, the fracture generally happens where the violence is immediately applied; but it may occur at a different part of the head, when produced by a body of a certain width. The poſſibility of fractures happening in a ſituation more or leſs diſtant from that which received the blow, is explicable on the principle of the unequal reſiſtance offered by the parietes of the cranium at different points of their extent. It is to ſuch caſes that the name of *counter-fiſſures* is given.

In order to explain the manner in which counter-fiſſures are produced, let us ſuppoſe a blow to fall upon the os frontis, with a force equivalent to twenty, which bone, being in the ſituation of the forehead ſomewhat thick, makes a reſiſtance equal to twenty-five. The ſolution of continuity, therefore, cannot happen directly in the place ſtricken; the force is tranſmitted to the orbitar proceſs, a part which is thin, eaſily broken, and only capable of making a reſiſtance expreſſed by twelve; conſequently the violence, though weakened in its tranſmiſſion, is ſtill ſufficient to fracture this laſt proceſs. The foregoing reaſoning coincides with experience. Many fractures of the orbitar proceſſes of the os frontis are met with in practice, while that part of the bone, which forms the forehead, remains free from injury. This firſt ſpecies of counter-fiſſure, though not exactly in the ſituation where the external violence was applied, happens on a part of the ſame bone which received the blow. There are other caſes, where counter-fiſſures occur on ſome bone adjoining that which was ſtricken, notwithſtanding the check which the impulſe muſt experience in croſſing the ſutures. Thus, blows on the parietal bone frequently break the ſquamous portion of the os temporis.

Such counter-fiſſures as happen to a part of the ſkull, diametrically oppoſite the point which received the blow, notwithſtanding the equal thickneſs of the bones in both places, admit of explanation by the imperfect ſpherical form of the cranium. Richerand, Noſog. Chir. tom. 2.

Fractures of the inner table of the ſkull, while the external is ſimply contuſed, are explicable by its great fragility, whence it has alſo been named by ſeveral authors *vitreous.*

Direct fractures, as well as counter-fiſſures, differ in point of ſituation, the extent of the ſolution of continuity, their particular ſhape, and the ſymptoms with which they are followed. Sometimes the crack is exceedingly fine and minute, which caſe is often called a *capillary fiſſure*. Sometimes the edges of the breach are attended with a ſeparation, more or leſs conſiderable. In ſome caſes, the fracture runs in a ſtraight line; in others it is ſtellated. In certain examples, the ſplinters of bone are beaten inwards, and compreſs the brain: theſe inſtances are uſually named *fractures with depreſſion.* On other occaſions, the broken pieces keep their proper level. But even in the latter ſort of caſe, the brain may ſuffer a dangerous degree of preſſure from an extravaſation of blood under the bone, ſuch preſſure, indeed, as may urgently require the application of the trephine. Yet, it ought to be well underſtood, that this operation is not performed becauſe the ſkull is broken, but becauſe the brain is dangerouſly compreſſed by a quantity of extravaſated blood, that lies confined under the bone, and was poured out of veſſels, which were ruptured by the ſame violence as broke the bone itſelf.

Not only may fractures of the ſkull be complicated with extravaſation, they may be conjoined with the effects of concuſſion. Depreſſed fractures are frequently accompanied with an actual laceration of the membranes and ſubſtance of the brain. The recoveries which have been known to follow the moſt terrible wounds of this organ, as detailed in the Memoirs of the French Academy of Surgery, are both curious and ſurpriſing. But, generally ſpeaking, the danger of all injuries of the head is in proportion to the miſchief and violence done to the brain. A fracture of the ſkull, could it be occaſioned, and exiſt without the leaſt irritation and diſturbance of the brain and membranes thereof, would be attended with no ſerious ſymptoms, and, of courſe, would require only ſimple treatment. In ſhort, the breach of continuity would be repaired with callus, juſt like a ſimilar injury in any other bone. It is the nearneſs of the brain, and the manner in which it is affected, either by the depreſſion or inequality of the bone, or by the blow itſelf, which conſtitute at once the importance and danger of all fractures of the cranium. The ignorant and injudicious are apt to think, that becauſe the ſkull is broken, the trepan muſt be employed, as a matter of courſe. Perhaps the doctrines of M. Queſnay, Pott, &c. might ſanction the invariable uſe of the trephine; for, if the argument be allowed, that this operation is proper as a *preventive* of the bad ſymptoms to be apprehended in caſes of fractured ſkulls, there cannot very well be any caſes where the practice would not be juſtifiable. Let not an opinion of ſuch conſequence, however, be taken up too haſtily, and we ſhall preſently adduce convincing reaſons againſt its validity.

We muſt firſt conſider what are the ſymptoms by which the exiſtence of a fracture of the ſkull may be known? It muſt be acknowledged, conſiderable obſcurity prevails in the diagnoſis of ſuch accident, unleſs it ſo happen, that the nature of the caſe admits of being aſcertained by the eye, or the touch. What are termed the *rational* ſymptoms are exceedingly fallacious. When a fracture of the ſkull occurs, attended with a wound of the ſcalp, and a denudation of the broken part of the bone, the ſurgeon may both ſee with his eyes, and feel with his fingers, what has happened. The exiſtence of a fracture may likewiſe be aſcertained by the touch, even when the ſoft parts are entire, if the ſolution of continuity in the bone is ſplintered, or accompanied with a conſiderable depreſſion. When ſeveral of the fragments are entirely detached, a palpable crepitus will often render the nature of the accident ſtill more clear.

Setting out of conſideration ſuch ſymptoms, there are none which can be regarded as characteriſtic of a fracture of the ſkull. Some writers direct us to enquire whether the patient was ſenſible, at the time of receiving the injury, of any noiſe, like that of a pot breaking. But how are we to gain information on this point from patients who are always ſtunned at firſt, and often remain ſenſeleſs and ſpeechleſs a long while afterwards? Other authors lay ſtreſs on the bleeding from the noſe and ears, a circumſtance entirely incidental, or, at moſt, indicative of nothing elſe, than that the head has ſuſtained ſome kind of blow, or concuſſion, without at all informing us of the degree of violence that has been applied. Beſides, every one knows what ſlight ſhocks will cauſe this kind of bleeding in particular perſons, ſo that it cannot be received as a proof that the blow has been very powerful. Even did it prove that the blow has been violent, it would not juſtify the inference, that the ſkull is certainly broken. In ſhort, we may aſſert, that a fracture of the cranium, without depreſſion, without extravaſation, and without concuſſion, is generally not only not productive itſelf of any alarming effects, but is alſo unmarked by any particular ſymptoms. Its exiſtence can only be aſcertained by the eye or the touch; and therefore its diagnoſis is only eaſy, when the injury is expoſed in conſequence of a wound. However, a ſurgeon need not be ſolicitous to find out an undepreſſed fracture; for if ſymptoms demand the application of the trephine, he is to apply it to the bone, whether it is fractured or not; and if theſe ſymptoms are abſent, the fracture itſelf cannot be a juſt reaſon for the operation.

We muſt not take our leave of the diagnoſis of theſe caſes, without cautioning ſurgeons not to be too haſty in pronouncing the ſkull to be fractured. Bloody tumours of the ſcalp often feel ſo much like fractures of the cranium with depreſſion, as to make the moſt experienced men incapable of a poſitive deciſion. Theſe caſes have already been noticed in the preſent article. When the bone is bare, it is poſſible to miſtake a ſuture, or the furrow of a blood-veſſel, for a fracture, and Hippocrates has gained conſiderable honour by the candour with which he acknowledged his having fallen into an error of this kind.

We ſhall conclude this ſubject with a few obſervations on the treatment of fractures of the ſkull. For the relief of theſe caſes, there cannot be a doubt that the uſefulneſs of trepanning has been moſt unreaſonably magnified. The neceſſity of only practiſing this operation when it is abſolutely requiſite, muſt be manifeſt to every one, who reflects, that cutting away a portion of the ſkull is a proceeding by no means free from the hazard of very dangerous conſequences. We have alſo the teſtimony of ſeveral eminent ſurgical writers, that it is an operation, generally ſpeaking, attended with remarkable ill ſucceſs. It is not our intention, however, to endeavour to inſinuate, that the fatal terminations are not chiefly aſcribable to the ſerious miſchief which commonly exiſts when the operation is performed. Be this as it may, we cannot help looking upon trepanning as a thing, to which recourſe ſhould never be had without ſtrong and urgent reaſon. Deſault, the moſt eminent of the modern French ſurgeons, entirely abandoned the operation in the latter years of his practice, as he found conſiderable ſucceſs ariſe from the employment of evacuations. "C'eſt une obſervation fort ancienne, que le peu de ſuccès de l'opération du trépan pratiquée à l'Hôtel-Dieu de Paris ; ſoit, que l'air des ſalles, vicié par le grand nombre d'individus, qui s'y trouvent raſſemblés, ou par l'humidité dont le voiſinage de la rivière le charge conſtamment, exerce ſur la place, que ſuccède l'opération, ou ſur les membranes du cerveau miſes à nu, une influence délétere, ſoit que ce fait conſtant dépende d'une autre cauſe ignorée, l'opération du trepan eſt preſque toujours ſuivie de la mort des individus." Richerand, Noſographie Chirurgicale, tom. ii. p. 266. Edit. 2.

That the operation of trepanning is itſelf not exempt from ſerious danger we moſt firmly believe. We have ſeen it prove fatal, when performed with a view of relieving a violent inveterate head-ache. Yet we cannot bring our mind to believe, that Deſault was right in rejecting the operation altogether. There certainly are caſes in which it may be the means of preſervation as well as others, in which it may exaſperate circumſtances and render them fatal.

We have noticed that, in fractures of the ſkull, the operation of trepanning was adviſed by Pott, as a *preventive* of ill conſequences. It gives us pleaſure to ſtate, that this practice is now never adopted by the moſt eminent ſurgeons in this country, great as their veneration is for ſo diſtinguiſhed an authority. Many modern writers of the higheſt reputation have forcibly remonſtrated againſt the method, as M. Deſault, of Paris ; Mr. Deaſe, of Dublin ; Mr. John Bell, of Edinburgh ; and Mr. Abernethy, of London.

The reader cannot be ſurpriſed, that fractures without depreſſion are not, abſtractedly conſidered, a juſt cauſe for trepanning, when he is informed, that the ſkull is often broken and depreſſed, and yet the ſymptoms may not be ſuch as to demand the operation, and the patient has the beſt chance of recovery when it is not performed. The more the preſent ſubject is ſtudied, the greater will be the conviction, that there is only one genuine reaſon for trepanning, and that is, when ſymptoms of a dangerous degree of preſſure on the brain exiſt, which ſymptoms are enumerated under the head of Extravasation. When they prevail, the operation is to be done, whether the ſkull is broken or not ; whether it be depreſſed or retain its proper level.

Mr. Abernethy has related ſeveral caſes of fracture of the cranium with depreſſion, which terminated favourably, although no operation was performed. This judicious ſurgeon thinks, that theſe caſes, as well as a great many others on record, prove, that a ſlight degree of preſſure does not derange the functions of the brain for a limited time after its application ; and all thoſe patients whom he had an opportunity of knowing for any length of time after the accident, continued as well as if nothing of the kind had happened to them. In Mr. Hill's Caſes in Surgery, two inſtances of this ſort are related, and Mr. Hill knew both the patients for many years afterwards ; yet no inconvenience aroſe. Indeed, it is not eaſy to conceive that the preſſure which cauſed no ill effects at a time when the contents of the cranium filled its cavity entirely, ſhould afterwards prove injurious when they have adapted themſelves to its altered ſize and ſhape. Severe illneſs, it muſt be confeſſed, does often intervene between the receipt of the injury and the time of recovery ; and many ſurgeons might be inclined to attribute this to the preſſure on the brain ; but it occurs quite as formidably when the depreſſed portion is elevated. If a ſurgeon, prepoſſeſſed with the opinion, that elevation of the bone is neceſſary in every inſtance of fracture of the ſkull with depreſſion, ſhould have acted upon this opinion in ſeveral of the caſes which Mr. Abernethy has related, and afterwards have employed proper evacuations, the patients would probably have had no fatal ſymptoms, and the recoveries would naturally have been imputed to the particular mode of treatment ; yet theſe caſes ended well without any operation.

It cannot be too often repeated, that the neceſſity of trepanning depends entirely on the urgency of the ſymptoms, which are known to proceed from the exiſtence of preſſure on the brain. (See Extravasation.) To trepan the ſkull merely becauſe it is broken, is as abſurd as to cut the arm becauſe it is fractured : it is only adding one ſpecies of violence to another. We have ſeen that, even when the fracture is depreſſed, it does not neceſſarily follow that the operation is proper : in fact, it is always improper, unleſs there are evident ſigns that the degree of preſſure, thus produced, is the cauſe of exiſting dangerous ſymptoms.

If, then, fractures of the cranium with depreſſion do not invariably require trepanning, it may readily be conceived, that the operation muſt be ſtill leſs frequently neceſſary when the fracture is undepreſſed. In ſuch caſe, indeed, the fracture itſelf can never demand this proceeding. But, nevertheleſs, it may be right and indiſpenſable on other accounts, ſince the brain may at the ſame time be dangerouſly compreſſed by an extravaſation of blood, or, in the courſe of the diſorder, by matter formed under the ſkull in conſequence of inflammation. However, it ſhould be well underſtood, that the inflammation and ſuppuration of the parts beneath the ſkull, which Mr. Pott was ſo anxious to *prevent* by trepanning early, do not ariſe from the occurrence of a breach in the cranium, but are chiefly, if not altogether, the conſequences of the ſame violence, which was the occaſion of the fracture. Hence, it is obvious, that removing a portion of the bone cannot have the leaſt tendency to prevent the inflammation and ſuppuration, which muſt inevitably reſult from the external violence that was firſt applied to the head ; but, on the contrary, ſuch a removal being an additional violence, muſt rather have the effect of increaſing the unavoidable inflammatory miſchief.

A fracture of the ſkull, unattended with urgent ſymptoms, and not brought into the ſurgeon's view by any accidental wound of the integuments, often remains for ever undiſcovered and unknown ; and as no benefit could ariſe from laying it bare by an inciſion, ſuch practice ſhould never be adopted. The practitioner ought only to make himſelf officious in this way, when he can accompliſh by it ſome better object than the merely ſatisfying his own curioſity. Now, ſince the removal of preſſure off the ſurface of the brain is the only admiſſible reaſon for ever perforating the cranium, and ſince dividing the ſcalp cannot be uſeful, unleſs preparatory to ſuch operation, it is clear that neither the one nor the other ſhould ever be done, excepting ſuch ſymptoms exiſt as unequivocally denote the prevalence of a dangerous degree of preſſure on the brain, cauſed either by matter, extravaſated blood, or depreſſed portion of the ſkull.

The true mode of *preventing* the bad effects frequently following, but not ariſing from ſimple fractures of the ſkull, (by which we mean caſes unaccompanied by urgent ſymptoms of preſſure,) is not to trepan, but to put in practice all kinds of antiphlogiſtic means. For this purpoſe, let the patient be repeatedly and copiouſly bled, both in the arm and temporal arteries; let him be properly purged; give him antimonials; keep him on the loweſt diet; let him remain in the moſt quiet ſituation poſſible; and if, notwithſtanding ſuch ſteps, the ſymptoms of inflammation of the brain continue to increaſe, let his head be ſhaven, and a large bliſter be applied to it. When, in ſpite of all theſe meaſures, matter forms under the cranium, attended with ſymptoms of preſſure, a puffy tumour of the injured part of the ſcalp, or thoſe changes of the wound (if there be one), which Mr. Pott has ſo excellently deſcribed, and we have already related; not a moment ſhould be loſt in delaying to perforate the bone with a trephine, ſo as to give vent to the matter collected underneath.

Before concluding, we have one important caution to offer, which is, in all caſes of injuries of the head from external violence, to continue an antiphlogiſtic regimen at leaſt a month after any ſerious accident of this deſcription; for it is by no means uncommon for inflammation of the brain to follow injuries of the head a very conſiderable time after the patients have had reaſon to fancy themſelves in perfect ſafety. Pott on Injuries of the Head; Diſeaſe on Wounds of the Head: Hill's Caſes in Surgery; Abernethy on Injuries of the Head; Cooper's Dictionary of Practical Surgery, &c.

Other ſubjects, immediately connected with the preceding, will be found under the articles COMPRESSION, CONCUSSION, EXTRAVASATION, and TREPANNING.

INK, a liquor wherewith to write on paper or parchment.

INK, *Printing*. See PRINTING.

INK, *Writing*, is commonly made of copperas and galls, and gum arabic; but other aſtringent plants may ſerve the ſame purpoſe; ſuch as oak-bark, red roſes, logwood, or ſumach. Mr. Boyle ſeems to doubt whether all aſtringent vegetables will do the ſame.

Many are the preparations and methods of compounding the materials for making of writing ink. For many years the ink moſt generally uſed by European writers has been the infuſion of galls and other aſtringent vegetables, containing gallic-acid, rendered black by ſulphate of iron, and thickened by the addition of a little gum or ſugar. This compoſition, however, is liable to fade; but ſince the diſcovery of the method of totally diſcharging the traces of common ink by the application of the oxigenated muriatic acid, more ſerious conſequences are to be apprehended from the univerſal uſe of the common atramentous fluid, than the decay of its colour from age; for it is well known that, while the ſulphate of iron remains on the paper, the colour of the writing may be reſtored by waſhing the MS. with freſh infuſion of galls. We have ſeveral receipts in Nicholſon's Philoſophical Journal, vol. iv. p. 479, 4to., for compoſing ink capable of reſiſting the oxigenated muriatic acid.

Macquer, in the Chemical Dictionary, gives the following receipt for making good ink. In four French pints of common water or beer, let a pound of bruiſed galls be infuſed twenty-four hours without boiling; to this add ſix ounces of gum arabic; and when the gum is diſſolved, ſix ounces of green vitriol, which will ſoon give it the black colour; the liquor is then to be ſtrained through a hair-ſieve.

The following method has been recommended by experience, and is eaſily and ſpeedily practiſed. To a gallon of boiling water, put ſix ounces of blue galls, groſsly pounded, and three ounces of copperas; ſtir the mixture well together, and then add ſix ounces of gum arabic pounded. After ſtirring the whole thoroughly, leave it to ſettle, and the next day ſtrain it off from the dregs for uſe. See IRIS *lutea paluſtris*.

The following compoſition will make a very good black writing ink. Take a gallon of ſoft water, and boil in it a pound of chips of logwood for about half an hour; pour the decoction boiling hot on a pound of the beſt Aleppo galls powdered, and two ounces of pomegranate peels, put into a proper veſſel. After having ſtirred them well together with a wooden ſpatula, place them in the ſunſhine in ſummer, or within the warmth of any fire in winter, for three or four days, ſtirring the mixture occaſionally; then add half a pound of green vitriol powdered, and let the mixture remain four or five days more, occaſionally ſtirring it; and then add four ounces of gum arabic diſſolved in a quart of boiling water; and after the ink has ſettled, ſtrain it off through a coarſe linen cloth, and keep it well ſtopped for uſe.

Mr. Delaval in his "Treatiſe on Colours," p. 37. informs us, that with an infuſion of galls and iron filings, he had not only made an exceedingly black and durable ink, but by means of it, without the addition of any acid, dyed ſilk and woollen cloth of a good and laſting black. But this kind of ink, though the colour is far ſuperior to that of any other, may be eaſily diſcharged, either by the ſmalleſt quantity of any acid, or even by ſimple water; becauſe it doth not penetrate the paper in ſuch a manner as is neceſſary to preſerve it from the inſtantaneous action of the acid or of the water. During the action of the infuſion of galls upon the iron in making this kind of ink, a very conſiderable effervеſcence takes place, and a quantity of air is diſcharged, the nature of which has not yet been examined.

Many of the more volatile kinds of oil may be uſed in writing, if reduced to a proper conſiſtence by the addition of gum or reſin. Tolerable ink may be made by diſſolving 30 grains of common reſin in 90 grains of oil of turpentine, and tempering the ſolution with 17½ grains of lamp-black, and 2½ of indigo. In a dry ſtate, this compoſition reſiſts the action of water, but not of ſpirit. Copal is much ſuperior to reſin; it will diſſolve in only few liquids. It may be diſſolved, however, in oil of lavender. The only inconvenience attending the uſe of copal in the compoſition of ink is, that it is ſoluble at a low temperature. Ink may be compoſed of oil of lavender, copal, and lamp-black in the manner following: Take oil of lavender 200 grains, copal, in powder, 25 grains, and lamp-black from 2½ to 3 grains. With the aſſiſtance of a gentle heat, diſſolve the copal in the oil of lavender in a ſmall glaſs phial, and then mix the lamp-black with the ſolution upon a marble ſlab, or other ſmooth ſurface. Put the compoſition into the bottle, and keep it from the air. After the repoſe of ſome hours, the ink muſt be well ſhaken, and ſtirred with a piece of wire before it is uſed; if it be too thick, it muſt be diluted with a little oil of lavender, oil of turpentine, or alcohol. The facility of writing with this compoſition depends much on the quantity of the colouring matter. Nicholſon's Journal, vol. ii. 8vo.

As the duration of records, and other valuable writings, depends much on the goodneſs of the ink employed, Dr. Lewis has thought this ſubject worthy of his attention. The chief imperfection of common inks is, that they decay in time, and at laſt the writing becomes inviſible. From experiments made by that author, he infers, that the decay of inks is chiefly owing to a deficiency of galls; that the galls are the moſt periſhable ingredient, the quantity of theſe, which gives the greateſt blackneſs at firſt (which is about equal parts with the vitriol) being inſufficient to maintain the colour; that for a durable ink, the quantity of galls cannot be much leſs than three times that of the vitriol; that it cannot be much greater without leſſening the blackneſs of the ink; that by diminiſhing the quantity of water, the ink was rendered blacker and more durable; that diſtilled water, rain water, and hard ſpring-water, had the ſame effects; that white wine produced a deeper black colour than water; that the colour produced by vinegar was deeper than that by wine; that proof ſpirit extracted only a reddiſh-brown tinge, and rectified ſpirit a paler brown; that the laſt mentioned tinctures ſunk into, and ſpread upon the paper; and hence the impropriety of adding ſpirit of wine to ink, as is frequently directed, to prevent mouldineſs or freezing; that other aſtringents, as oak bark, biſtort, ſloe-bark, &c. were not ſo effectual as galls, nor gave ſo good a black, the colour produced by moſt of theſe, excepting oak-bark, being greeniſh; that the juice of ſloes did not produce a black colour with martial vitriol; but that, nevertheleſs, the writing made with it became black, and was found to be more durable than common ink; that inks made with ſaturated ſolutions of iron in nitrous, marine, acetous acids, in tartar, or in lemon juice, were much inferior to the ink made with martial vitriol; that the colour of ink was depraved by adding quicklime, which was done with an intention of deſtroying any ſuperabundant acid which might be ſuppoſed to be the cauſe of the loſs of the colour of the ink; that the beſt method of preventing the effects of this ſuperabundant acid is probably by adding pieces of iron to engage it; and that this conjecture was confirmed by an inſtance the author had heard, of the great durability of the colour of an ink in which pieces of iron had been long immerſed; and laſtly, that a decoction of logwood uſed inſtead of water, ſenſibly improved both the beauty and deepneſs of the black, without diſpoſing it to fade. The ſame author obſerves, that the addition of gum arabic is not only uſeful, by keeping the colouring matter ſuſpended in the fluid, but alſo by preventing the ink from ſpreading, by which means a greater quantity of it is collected on each ſtroke of the pen. Sugar, which is ſometimes added to inks, was found to be much leſs effectual than gums, and to have the inconvenience of preventing the drying of the ink. The colour of ink is found to be greatly injured, by keeping the ink in veſſels made of copper, or of lead, and probably of any other metal excepting iron, which the vitriolic acid can diſſolve. The foregoing experiments point out for the beſt proportions of the ingredients for ink; one part of green vitriol, one part of powdered logwood, and three parts of powdered Aleppo, or blue galls. The beſt menſtruum appears to be vinegar or white wine, though for common uſe water is ſufficient. If the ink be required to be of a full colour, a quart, or at moſt three pints, of liquor may be allowed to three ounces of galls, and to one ounce of each of the other two ingredients. Half an ounce of gum may be added to each pint of the liquor; though the more gum we can employ, conſiſtently with due freedom of writing, it is probable that the ink will be the more durable. The ingredients may be all put together at once in a convenient veſſel, and well ſhaken four or five times each day. In ten or twelve days the ink will be fit for uſe, though it will improve by remaining longer on the ingredients; or it may be made more expeditiouſly, by adding the gum and vitriol to a decoction of galls and logwood in the menſtruum. To the ink, after it has been ſeparated from the feculencies, ſome coarſe powder of galls, from which the fine duſt has been ſifted, together with one or two pieces of iron, may be added, by which its durability will be ſecured.

It has been often remarked, ſays the ſame ingenious writer, that the inks uſed in former times were far more durable than thoſe of later years; many modern records being more decayed than manuſcripts of much greater antiquity, of which we have inſtances in the Letters of Camillo Paderni, publiſhed in the Philoſophical Tranſactions for 1753 and 1754. Dr. Lewis made ſeveral experiments, in order to recover the compoſition of this durable ink. Inſtead of oil which is uſed in the printers' ink, he mixed both lamp-black and ivory-black with a ſolution of gum arabic; this liquor wrote of a fine black colour, but when dry, it rubbed off entirely by moiſture. Concluding, therefore, that the colour could not be ſufficiently fixed on paper without an oily cement, and as oils are made miſcible with watery fluids by the intervention of gum, he mixed ſome of the ſofter printers' varniſh with about half its weight of a thick mucilage of gum arabic, working them well together in a mortar, and beat this maſs with lamp-black, adding water by little and little, and continuing the rubbing, till the mixture became of a due conſiſtence for writing. This produced characters of a full browniſh black colour, which could not be diſcharged by rubbing, nor waſhed out ſo readily as the foregoing. Inſtead of the printers' varniſh, or boiled oil, linſeed-oil was mixed in the ſame manner with mucilage and lamp-black, and the mixture diluted with water; and the ink thus obtained was much the ſame as the other. To prevent the diſcharge by water, ſome of the more ſinking kinds of paper, or common paper made damp as for printing, muſt be uſed, which will admit the ink to ſink a little into its ſubſtance; and thus the characters will be as fixed as can be deſired. Such Dr. Lewis found to be the ancient inks, that were ſo durable. Pliny and Vitruvius expreſsly mention the preparation of ſoot, or lamp-black, and the compoſition of writing ink from lamp-black and gum. Dioſcorides ſets down the proportion of three ounces of the ſoot to one of gum. This mixture was formed into cakes or rolls, and dried in the ſun, which were occaſionally tempered with water, as the Indian ink is with us for painting. The ancients were ſenſible that theſe inks were liable to be diſcharged by water, and endeavoured to obviate this imperfection, according to Pliny, by uſing vinegar, inſtead of water, for tempering the mixture of lamp black and gum, which promotes the ſinking into the paper. After all, none of theſe inks can be diſcharged otherwiſe than by deſign; which is the caſe with reſpect to the vitriolic inks, and thoſe of printed books and copper-plates.

In the courſe of Dr. Lewis's experiments, a farther improvement occurred to him, which was that of uſing the common vitriolic ink, inſtead of water, for tempering the ancient mixture of gum and lamp-black. By this method the writings will have the durability of thoſe of former times, with all the advantage that reſults from the vitriolic ink fixing itſelf in the paper. Common writing ink may, in many caſes, be improved by a ſmall addition of the ancient compoſition, or of the common Indian ink. Lewis's Commerce of Arts, &c. § 16.

Mr. Aſtle, in his "Origin of Alphabetical Writing," inculcates the neceſſity of making ink durable; and for this purpoſe ſuggeſts a compariſon of the rolls and records that have been written from the 15th century to the end of the 17th, with the writings that remain from the 5th to the 12th centuries. Theſe are in excellent preſervation; but the former, though of more modern date, are defaced to ſuch a degree that they are ſcarcely viſible. Mr. Aſtle agrees with Dr. Lewis in the opinion, that the ancient inks were compoſed of ſoot or ivory black inſtead of the galls, copperas, and gums, which form the compoſition of our's. Beſides their black ink, the ancients uſed various other colours, as red, gold and ſilver, purple, &c. Green ink was frequently uſed in Latin MSS., eſpecially in the latter ages: and it was frequently employed in ſignatures by the guardians of the Greek emperors till their wards were of age. Blue or yellow ink was ſeldom uſed except in MSS., but, according to Mr. Aſtle, the yellow has not been much in uſe for theſe 600 years. Some kinds of characters, particularly the metallic, were burniſhed. Wax was uſed by the Latins and Greeks as a varniſh, eſpecially by the former, and particularly in the 9th century. This continued a long time in vogue. Dr. (ſir Charles) Blagden, in the Phil. Tranſ. vol. lxxvii. p. 451, &c. has propoſed a new method of recovering the legibility of decayed writings. With this view he made ſome experiments on parchment and vellum MSS., with which he was furniſhed by Mr. Aſtle, employing thoſe chemical re-agents which ſeemed beſt adapted to his purpoſe, *viz.* alkalies, both ſimple and phlogiſticated, the mineral acids, and infuſion of galls. The general reſult ſhewed, that the ink anciently uſed, at leaſt in theſe MSS., was of the ſame nature as the preſent; and the greater durability of the more ancient inks appeared to depend very much on a better preparation of the material upon which the writing was made, *viz.* the parchment or vellum. He ſuſpected, however, that the ancient inks contained a rather leſs proportion of iron than the more modern; and perhaps more gum was uſed then, or poſſibly they were waſhed over with ſome kind of varniſh, though not ſuch as gave any gloſs. It occurred to our author, in the courſe of his experiments, that perhaps one of the beſt methods of reſtoring legibility to decayed writings might be to join phlogiſticated alkali with the remaining calx of iron. In order to bring this idea to the teſt, he made ſeveral experiments, for which we refer to his paper, ubi ſupra. The method now commonly practiſed to reſtore old writings is the wetting of them with an infuſion of galls in white wine. This has certainly a great effect: but, like the phlogiſticated alkali, it is apt to ſtain the ſubſtance in which the writing was made. Sir Charles Blagden ſuggeſts, that a phlogiſticated alkali, better adapted to this purpoſe than the common, might be prepared, by rendering it as free as poſſible from iron, diluting it to a certain degree, or ſubſtitutng the volatile alkali for the fixed. This would ſerve to bring out a prodigious body of colour upon letters which were before ſo pale as to be almoſt inviſible, and it would be preferable to the infuſion of galls in this reſpect, that it produces its effect immediately, and may be confined to thoſe letters only for which ſuch aſſiſtance is wanted.

In the "Monthly Review" of the volume of Tranſactions above cited, the following method is propoſed for preventing ink from decaying. It conſiſts in waſhing over the paper on which the writing is to be made with the colouring matter of Pruſſian blue; and by writing upon it afterwards with common ink, a ground of Pruſſian blue is formed under every ſtroke; which will remain ſtrong after the black has been decayed by the weather, or deſtroyed by acids. The ink will thus bear a larger proportion of vitriol at firſt, and will have the advantage of appearing blacker when firſt written.

INK *Powder* may be prepared, by infuſing a pound of galls powdered, and three ounces of pomegranate-peels, in a gallon of ſoft water for a week, in a gentle heat; and then ſtraining off the fluid through a coarſe linen cloth. Add to it eight ounces of vitriol diſſolved in a quart of water, and let them remain for a day or two; preparing in the mean time a decoction of logwood, by boiling a pound of the chips in a gallon of water, till one-third be waſted, and then ſtraining the remaining fluid while it is hot. Mix this decoction and the ſolution of galls and vitriol together, and add five ounces of gum arabic, and then evaporate the mixture over a common fire to about two quarts; when the remainder muſt be put into a veſſel proper for that purpoſe, and reduced to dryneſs in *balneo Mariæ*, i. e. by hanging the veſſel in boiling water. The remaining maſs, after the fluid is wholly exhaled, muſt be well powdered; and when it is wanted for uſe, may be converted into ink by the addition of water.

A portable or extemporaneous ink may be made without galls or vitriol, by mixing half a pound of honey and the yolk of an egg, adding two drams of gum arabic finely levigated, and thickening the whole with lamp-black to the conſiſtence of a ſtiff paſte; which being put to a proper quantity of water, may be uſed as an ink.

INK, *Indian*, or *Chineſe*, is an admirable compoſition, in vain attempted to be imitated in Europe. It is not fluid, like our writing inks, but ſolid, like our mineral colours, though much lighter. They make it of all figures, but the moſt uſual is rectangular, about a quarter of an inch thick. Some of the ſticks are gilt with figures of dragons, birds, flowers, &c. In order to do this, they have little wooden moulds, ſo curiouſly wrought, that we could hardly equal them in metals.

To uſe this ink, there muſt be a little hollow marble, or other ſtone, with water in it, on which the ſtick of ink muſt be ground, till the water becomes of a ſufficient blackneſs. It makes a very black ſhining ink; and though it be apt to ſink when the paper is thin, yet it never runs or ſpreads; ſo that the letters are always ſmooth, and evenly terminated, how big ſoever they be. It is of great uſe in deſigning, becauſe it may be weakened or diminiſhed to any degree; and there is abundance of things which cannot be repreſented to the life without it.

From an analyſis of this ink, Dr. Lewis concludes that it contains an animal ſubſtance ſoluble in water, and conſiſts of a black powder, mixed with ſome animal glue. He tried to imitate it, by mixing ſome lamp-black, prepared from linſeed-oil, by hanging a large copper pan over the flame of a lamp to receive its ſmoke with as much melted glue as gave it ſufficient tenacity for being formed into cakes. Theſe cakes, when dry, anſwered as well as the genuine Indian ink, in regard both to the colour, and the freedom and ſmoothneſs of working. Ivory black, and other charcoal blacks, levigated very fine, had the ſame effect with the lamp-black. It appears from three receipts for the preparation of Indian ink, in Du Halde's Hiſtory of China, that the colouring material is lamp-black, to which is added, in one of them, a quantity of horſe-cheſnuts, burnt till the ſmoke ceaſes. The conglutinating matter, in one of the preſcriptions, isa thin ſize of neat's leather; in another, a ſolution of gum tragacanth, and in the other, a mixture of ſize, with a decoction of certain vegetables, unknown to us. Du Halde obſerves, that the Chineſe have inks of different goodneſs and price; that the moſt eſſential difference proceeds from the quality of the lamp-black, and that the beſt is the ſoot of oil, burnt in lamps, in apartments fitted up for this purpoſe.

The Chineſe have often attempted to uſe this in their porcelain, to give the colour of black to the figure traced on white veſſels, but it has been a vain attempt; for however beautiful and ſtrong the figures might appear when firſt laid on, and even when the veſſels were dried, it all diſappeared on the baking, and they came out quite white as they were put in. The colours for this uſe muſt be ſuch as can penetrate the varniſh, and endure the fire. Mineral colours are found to have theſe qualities, and theſe alone therefore are to be employed; ſuch light ones as this black burning off from the ſurface, and wholly diſappearing. Obſ. ſur les Coûtumes de l' Aſie, p. 329.

Ink is alſo an appellation given to any coloured liquor uſed in the ſame manner as black ink; as red, green, blue, yellow, &c. inks. *Red* writing ink is prepared by infuſing a quarter of a pound of the raſpings of Brazil wood for two or three days in vinegar; boiling the infuſion for an hour over a gentle fire, and afterwards filtering it, while hot, through paper laid in an earthen cullender; then put it again over the fire, and diſſolve in it, firſt, half an ounce of gum arabic, and afterwards alum, and white ſugar, of each half an ounce. Red ink may be alſo made of vermilion, by beating together the glair of four eggs, a tea-ſpoonful of white ſugar, or ſugar-candy, powdered, and as much ſpirit of wine, till they be of the conſiſtence of oil; then adding ſuch a proportion of vermilion as will produce a red colour of ſufficient ſtrength; the mixture ſhould be kept in a ſmall phial, or well-ſtopt ink bottle, and well ſhook before it be uſed. Gum-water is often uſed inſtead of the glair of eggs; but thin ſize made of iſinglaſs, with a little honey, is much better for the purpoſe. Red ink may be made by tempering the ſolution of copal with red ſulphuret of mercury, *e.g.* take of oil of lavender, 120 grains, copal, in powder, 17 grains, and red ſulphuret of mercury, 60 grains, diſſolve the copal in the oil, and then mix the ſulphuret with the ſolution upon a ſmooth ſurface. This, and alſo the black ink made with copal, poſſeſs a permanent colour, and other eſſential properties of the ink uſed in printing. The oil of lavender being diſſipated with a gentle heat, the colour is left on the paper ſurrounded with copal, a ſubſtance inſoluble in water, in ſpirits, in acids, or in alkaline ſolutions.

For red printing ink, ſee Printing.

Green ink may be made, by putting an ounce of powdered verdigris to a quart of vinegar, and ſtraining the fluid, after it has ſtood two or three days: or, inſtead of this, the cryſtals of verdigris diſſolved in water will anſwer the purpoſe; then diſſolve in a pint of either of theſe ſolutions, five drams of gum arabic, and two drams of white ſugar.

Blue ink is made by grinding indigo with honey and the white of eggs, and making it fluid with water.

Yellow ink is made by an infuſion of ſaffron in water, with a little alum and gum arabic: or, by boiling two ounces of Avignon, or French berries, in a quart of water, with half an ounce of alum, till one-third of the fluid be evaporated, and then diſſolving in it two drams of gum arabic, and one dram of ſugar, and afterwards a dram of powdered alum.

In general, inks of all colours may be made by uſing a ſtrong decoction of the ingredients uſed for dyeing, mixed with a little alum and gum arabic. See the ſeveral colour Blue, Green, &c.

Inks, *Sympathetic*, or *Secret*. Every ſort of liquor with which a perſon may write, ſo that the letters do not appear till there is ſome particular means uſed to give them a colour different from that of the paper, is called by the name of *ſympathetic* ink; and of this there are a great many kinds deſcribed in the writings of Baptiſta Porta, Lemery, and other authors.

All theſe inks may be regularly diſtributed into different claſſes, according to the different means which are to be uſed to make them appear; and theſe are in general the four following. 1. By giving a new liquor, or the vapour of new liquor, a place on the paper, on which the letters are written with the natural inviſible ink. 2. By expoſing the paper to the air, by which means the letters at firſt inviſible will appear. 3. By paſſing gently over the letters a matter of ſome remarkable colour reduced to fine powder. And 4. By expoſing the paper to the fire.

This laſt is by much the beſt method, and is ſo general, that it may be prudently uſed to all papers ſuſpected of containing any ſecret writing, as it ſeldom fails to diſcover it. All the common inks of this kind, however, when they have been once made to appear, either by fire or by any other method, can never be made to diſappear again; but there is one kind deſcribed by Mr. Hellot, in the Memoirs of the Academy of Sciences at Paris, and ſince tried many times with us, and elſewhere, which, though the letters it gives are in themſelves inviſible, and appear like thoſe of ſome other of theſe inks, on their being held to the fire, yet they after that will fade and diſappear on the paper again, and may be reproduced in this manner ſeveral times. This, therefore, is the firſt known ink of a fifth general claſs, of which future reſearches may diſcover perhaps more.

Of the firſt claſs of ſympathetic inks, or thoſe which do not appear till the paper on which they are written be made to imbibe another liquor, or the vapour of another liquor, are the following kinds.

To two or three parts of unſlaked lime put one of yellow orpiment; powder and mix the two, adding fifteen or ſixteen times as much water as there was orpiment; ſtop up the phial with a cork and bladder, and ſet it in warm embers; ſhake the phial now and then for five hours, and warily decant the clear part, or rather filtrate it. In the room of this preparation may be uſed a ſaturated ſolution of common brimſtone, made by boiling the brimſtone either with quicklime, or in ſtrong alkaline ley. In the mean time, burn a piece of cork thoroughly, and when well inflamed, quench it in common water, or rather in brandy. Being thus reduced into a friable coal, grind it with fair water, wherein gum arabic has been diſſolved; and it will make a liquor as black as the common ink.

While theſe are doing, diſſolve, in three times as much diſtilled or ſtrong vinegar, over warm embers, a quantity of red lead, or of ſaccharum ſaturni, in thrice the quantity of water, for three or four hours, or till the liquor have a ſweet taſte. This liquor will be as clear as common water. Solutions of lead in aquafortis anſwer the ſame end, except that, when written with, they are apt to corrode the paper.

The liquors thus prepared, write any thing on paper with this laſt ſort, dry it, and nothing will appear. Over the place, write what you pleaſe with the ſecond liquor: it will appear as if written with common ink: when dry, dip a ſmall piece of rag or ſpunge, in the firſt liquor, rub it over the written place, and the black writing will vaniſh; and that wrote with the inviſible ink will appear black and legible.

Again, take a book four or five inches thick, and on the firſt leaf write any thing with the laſt liquor; turn to the other end of the book, and rub there with a rag, dipt in the firſt liquor, on that part, as near as you can gueſs, oppoſite to the writing, and leave alſo the rag there, clapping a paper over it; then nimbly ſhutting the book, ſtrike four or five ſmart ſtrokes thereon with your hand, and turning the other ſide uppermoſt, clap it into a preſs, or lay it under a good weight for a quarter of an hour, or even half that time; then will the writing done with the inviſible ink be found legible there.

The above operation may be varied, by writing the inviſible characters with the ſolution of biſmuth in nitrous acid, and expoſing them to the vapours of liver of ſulphur, or moiſtening them with a ſolution of liver of ſulphur.

Diſſolve white or green vitriol in water, and writing with the ſolution, nothing will appear. Boil galls in water, and dip a linen rag in the decoction, and with it rub the place before writ, and it will appear black and legible. Rub it over again with ſpirit of vitriol, or its oil, and the writing will diſappear again; rub it over again with oil of tartar per deliquium, the letters will appear again, but of a yellow colour. If the blackneſs of ordinary ink be deſtroyed by a ſufficient quantity of nitrous acid, the writing made by it will remain inviſible till it be moiſtened with liquid fixed alkali.

The golden ſympathetic ink.—This is made by diſſolving in aqua regia as much gold as that menſtruum can take up, and then adding to the liquor five or ſix times as much water; in another veſſel there muſt be ſome tin diſſolved in aqua regia; and when that menſtruum has alſo taken up as much of the metal as it can, there is to be added to it an equal quantity of common water. The letters muſt be written on white paper with the ſolution of gold, and the writing being dried in the ſhade, the letters will not appear, at leaſt not for ſeven or eight hours afterwards; dip a pencil in the ſolution of tin, and rub that over the ſolution of gold with which the letters were written, and they will appear of a beautiful purple. It might be ſuppoſed, that any other metals which were ſoluble in the ſame acid menſtruum would equally produce this effect; but experiment ſhews, that this is not the caſe; and ſilver and copper, though both ſoluble in aquafortis, yet produce no change of colour by theſe precipitations made by mixing the ſolutions of them on paper; and this example of ſuch an effect in the ſolutions of gold and tin, is an exception to the general rules in the ſolutions of metals, and their effects on one another.

The purple colour of theſe letters may be again effaced by rubbing ſome ſimple aqua regia over the paper, and may be made to appear again by rubbing over that the ſolution of tin. Kunkel, Caſſius and Orſchal, with ſome other writers, made the firſt ſteps towards this diſcovery, by their attempt to give cryſtal, by means of gold, the colour of the oriental rubies. There are, beſide theſe mineral preparations, ſome vegetable ones, which give the ſame phenomena, but theſe are the more certain.

Of the ſecond kind of ſympathetic inks, or thoſe which appear on being expoſed only to the air, is the golden ink made by adding to a ſolution of gold in aqua regia, ſo much water that the liquor ſhall not ſtain a white paper: letters written with this will not appear till the paper has been expoſed ſome hours to the open air, and they will then begin to acquire a colour by degrees, till they at length become of a deep violet colour, tending to black. If, inſtead of expoſing the paper to the air, it be kept in a box cloſe ſhut up, or cloſely folded in other paper, it will remain inviſible two or three months; but at the end of that time it will begin to appear, and will by degrees become of a deep violet colour. So long as the gold remains united to its diſſolvent, it is yellow; but the acid that diſſolves it being of a volatile nature, the greater part of it evaporates, and leaves no more than is juſt neceſſary to colour the calx of gold which remains upon the paper.

The ſecond of theſe is the ſilver ink, made by a ſolution of ſilver in aquafortis, weakened by diſtilled water, till it will not ſtain the paper. Letters written with this will be inviſible for three or four months, if ſhut up in a box; but if they be expoſed to the ſun they become legible in about an hour, becauſe by this means the evaporation of the acid is accelerated. The letters written with this ink are of a ſlate colour; and that from the ſulphureous nature of the aquafortis, every thing that is ſulphureous blackening ſilver. This blackiſh colour, however, is not permanent; for the ſulphureous part finally evaporating, the letters are left to their natural appearance, and are of a fine true ſilver colour, if the ſilver that was uſed was fine, and the place open.

In this claſs there may alſo be placed ſeveral metallic diſſolutions; as that of lead in vinegar, and of copper in aquafortis, which give at length a browniſh colour upon the paper; as alſo the ſolution of tin in aqua regia, of mercury in aquafortis, of iron in vinegar, of emery and ſeveral of the pyritæ in ſpirit of ſalt. But all theſe, though they give letters which are after ſome time legible, on being expoſed to the air, are alſo made to appear inſtantly on the paper, holding them to the fire. Each of theſe ſolutions gives its own particular colour; but they have all this diſadvantage, that in time they eat away the paper, and the letters are ſeen in the ſhape of ſo many holes.

Of the third claſs of ink, or that which appears on rubbing over the paper with a brown or black powder, are almoſt all the glutinous expreſſed juices of plants, which are themſelves of no remarkable colour, the milk of animals, or any other thick and viſcous fluids. To uſe theſe, the letters muſt be written on a white paper, and when dry, there is to be thrown over them the fine powder of any coloured earth, or other ſuch ſubſtance; and the writing will afterwards appear coloured, becauſe its viſcous quality remains ſufficiently in it for the entangling and retaining this fine powder, though it falls eaſily off from every other part of the paper. Mem. Acad. Science, Par. 1737.

Among the methods which Ovid teaches young women to deceive their guardians, when they write to their lovers, he mentions that of writing with new milk, and of making the writing legible by coal-duſt, or ſoot.

> “ Tuta quoque eſt, fallitque oculos, e lacte recenti
> Litera: carbonis pulvere tange: leges.”
> De Arte Amandi, l. iii. v. 629.

Auſonius propoſes the ſame means to Paulinus, and he afterwards teaches other methods of ſecret writing. Auſon. Epiſt. xxiii. v. 21, &c. Eneas, in Poliorceticis, cap. 31, and Gellius, lib. xvii. cap. 9, mention the like. Pliny, lib. xxvi. cap. 8. mentions the milky ſap of certain plants for a ſimilar purpoſe.

Of the fourth claſs, or thoſe inks which become viſible on holding them to the fire, there are a vaſt number; and indeed all infuſions, the matter of which is readily burnt to a ſort of charcoal by a little fire, will anſwer this purpoſe. The niceſt of this kind is the ſal ammoniac ink, made by diſſolving a ſcruple of ſal ammoniac in two ounces of fair water. Letters written with this ſolution are inviſible on the paper, till it is held before the fire, or has an iron a little heated paſſed over it. The rationale of this is, that the inflammable part of the ſal ammoniac is burnt to charcoal by a heat which is not ſufficient to ſcorch the paper; and this is the caſe with all the reſt of this claſs. The letters written with this ſolution are, however, of no great duration; for the ſalt being apt to moiſten in the air, the letters ſoon ſpread, and run together in a confuſed manner.

Dr. Lewis ſays, that all the ſalts which he has tried produce this effect in a greater or leſs degree; nitre, alum, tartar, very weakly; ſea-ſalt more ſtrongly; fixed alkaline ſalts ſtill more ſo; but ſal ammoniac the ſtrongeſt of all. Metallic ſolutions, made in acids, and diluted ſo as not to corrode the paper, act in the ſame manner. The juice of lemons and milk have alſo been uſed as ſympathetic inks, the writing with which appears upon the application of heat ſufficient to decompoſe the oily and mucilaginous parts of theſe liquors.

The fifth claſs of ſympathetic ink contains only one yet known kind.

This, though in itſelf inviſible, becomes of a blueiſh green when held to the fire; and this colour diſappears again as the paper cools, and is to be produced again on holding it again to the fire: and this for a long time, and a repeated ſeries of trials. It may alſo, according to the different manner of treating it, be made to appear blue, green, yellow, red, and ſome other colours. This property of the tinging matter of biſmuth ore was publiſhed at full length by a German lady, in 1705.

A certain German chemiſt ſhewed the academy at Paris a ſalt of roſe-water, which became blue on holding it to the fire, and at the ſame time ſhewed the ore from which he procured the ſalt, which he called an ore of marcaſite, a name given by many to the biſmuth ore. He added, that this was the mineral from which the fine blue ſmalt of Sneeberg was prepared, and that no other ore but this afforded it, and that he made the tincture from this mineral with aquafortis, which he fixed with ſea-ſalt.

This was the ſubſtance of what the German declared, and from what Mr. Hellot, in 1736, took the hint for his diſcovery of this remarkable ink. The ſalt was, after many experiments, at length found to be produced from an arſenic ore; and it was found, that all the cobalts and ores of biſmuth afford a tincture capable of theſe changes by fire.

The method of preparing it is this: pour upon two ounces of arſenic ore, groſsly powdered, a mixture of five ounces of aquafortis, and five ounces of common water. After the firſt ebullition is over, place the veſſel in a gentle ſand-heat, and let it ſtand there till no more air-bubbles ſeem to aſcend; after this increaſe the fire, ſo as to make the liquor boil for about a quarter of an hour; after this the liquor will become of a reddiſh colour, and when cold it is to be decanted clear off from this ſediment into a phial; and after ſtanding in that ſome time, it is to be again decanted off from what is precipitated there; and ſo on for three or four times till it is quite clear; for it muſt not be filtered, leſt the acid ſhould take ſomething from the paper that might ſpoil the effects. When the liquor is clear, there muſt be added to it two ounces of white ſea-ſalt: this mixture is to be evaporated over a gentle ſand-heat, till there remains only a dry ſaline maſs. When the liquor is grown hot, it changes from its orange colour to a fair red; and when the aqueous humidity is evaporated, it becomes of a beautiful emerald colour, and from this, as it dries up, it changes by degrees to a dirty green, like that of verdigris in the cake. As it becomes nearly dry, it muſt be ſtirred about with a glaſs rod or peſtle, to keep it from uniting into a maſs; and it muſt not be kept over the fire till perfectly dry, becauſe by that means the colour is often loſt, and the ſalt from green becomes of a duſky yellow; but if it be taken from the fire while it is green, it gradually becomes reddiſh as it cools, and finally is of a roſe-colour. The manner of uſing this ſympathetic ink is this: write with it on a fine and ſmooth paper, or draw with a black-lead pencil the figure of a plant or tree on the paper; then trace over the ſame lines with this liquor; let it dry in the open air, and then rub off the black lines with bread, and the paper will appear altogether fair, though the lines made by the ink are in reality ſunk deep into it. On holding this paper to the fire the lines will all appear, and the figure of the plant or the letters will be painted in a beautiful blueiſh green, which will continue ſo long as the paper is warm; but when it is cold again, they will wholly diſappear. The lines, therefore, diſappear much ſooner in winter than in ſummer; and in very hot weather it is often neceſſary to lay the paper on a marble, or other very cold body, in order to produce this effect. At any time, if the paper be ſcorched in the experiment, the colour of the lines will not diſappear again, even if ice be laid upon them. If the writing be expoſed for three or four days to a humid air, the lines will appear of a fine pale red. If the impregnation of the ore of biſmuth, inſtead of ſea-ſalt, have alum added to it, and the whole proceſs be continued as before deſcribed; and if letters be written with the red liquor as it is taken out of the veſſel, the letters will not appear even on holding it to the fire; but if the paper be wetted over with a clear ſolution of marine ſalt, and then left to dry, and afterwards held to the fire, the letters will appear blue. The ſame alſo will be the effect, if the writing be expoſed to the vapour of hot ſpirit of ſalt. When this preparation is thus made with alum, inſtead of common ſalt, the liquor never becomes green, but continues red, and never changes colour in the drying, or afterwards. The green colour ſeems to be wholly the effect of the ſea-ſalt; for not only this aluminate impregnation, but others in which other ſalts had been employed, were always found to be of a different colour.

Glauber's ſalt, uſed inſtead of common ſea-ſalt, left the maſs red in the ſame manner as alum did. Nitre added, inſtead of ſea-ſalt, gave the precipitate or dried ſalt a beautiful purple colour, which became white on the inſtant that water was poured upon it, and a roſe-coloured tincture was drawn from it, which gave lines or letters on paper, which continued inviſible as long as they were cold, but aſſumed a beautiful red on holding the paper to the fire; which colour they retained no longer than while the paper continued warm, diſappearing afterwards in the ſame manner with the green colours made by the ſea-ſalt; and if a ſimple ſolution of ſea-ſalt be rubbed over the paper, and ſuffered to dry, and the paper be afterwards heated, the lines appear blue. Borax has the ſame effect in this preparation with the nitre. All theſe experiments were made with the neutral ſalts; but in order to try what would be the effects of alkalies in the mixture, Mr. Hellot added to three ounces of the impregnation of the ore in aquafortis, pure ſalt of tartar, till the ebullition ceaſed; but the conſequence of this was no great precipitation, but merely the ſubſiding of a ſmall white ſediment; this mixture being evaporated nearly to a dryneſs, the remaining maſs, ſo long as it was warm, appeared of a beautiful purple; but this became paler as it dried, and turned white in an inſtant on pouring

ing water upon it. This diſſolved in water, in the manner of the others, gave lines on paper of a faint roſe-colour, which appeared or diſappeared in the manner of thoſe made by the other ſolutions, according as the paper was hot or cold; and the wetting of the paper with a ſolution of ſea-ſalt, had the ſame effects on this as on the others, making the lines appear blue on holding to the fire. Mem. Acad. Par. 1737. See *Colours from* Metals.

The ink may be eaſily made by digeſting zaffre, commonly ſold by druggiſts, in aqua regia; and thus is obtained the ſoluble part of zaffre, which is the calx of cobalt. This ſolution is then to be diluted with a little common water. In expoſing the paper written with this ſolution to the fire, care muſt be taken not to heat it too much; for in this caſe, the writing will not again diſappear by expoſure to cold. This ink, ſays Macquer, the author of the Chemical Dictionary, may be applied to the drawing of landſcapes, in which the earth and trees deſtitute of verdure, being drawn with common ink, give a proſpect of winter; and which may be made to aſſume the appearance of ſpring, by expoſure to a gentle heat, which covers the trees with leaves and the earth with graſs, by rendering viſible thoſe parts of the landſcapes which are drawn with this ſympathetic ink; and, as the ſolution of regulus of cobalt or zaffre in ſpirit of nitre acquires a reddiſh colour by the application of heat, the red ſolution might be contrived to repreſent the fruits and flowers.

Ink-*fiſh*, in *Ichthyology*. See Cuttle-*fiſh*, and Sepia.

INLAGATION, Inlagatio, a reſtoring of one outlawed to the protection of the law and benefit of a ſubject.

The word comes from the Saxon *inlagium, i. e. inlagare.* Terms of Law.

INLAGH, Inlagatus, he that is of ſome frank-pledge, and not out-lawed. It ſeems to be the contrary to *utlagh*.

INLAND implies any thing ſituate in the main land, or heart of a country, far from the ſea-coaſts.

Hence inland bills, in traffic, are ſuch bills as are payable in the ſame land, wherein they are drawn. See Bill.

Inland *Navigation,* is applied to the paſſage of boats, barges, and veſſels on canals and navigable rivers, within a country, to diſtinguiſh it from navigation, properly ſo called, by means of ſhips on the open ſeas or the largeſt of the lakes. No country in the world can vie with the Britiſh iſlands at the preſent day, for the extent and importance of their artificial inland navigation or Canals, under which article we have given a connected view of theſe, and of the navigable rivers and railways, forming altogether a ſyſtem of improved communication no where to be equalled; and yet nearly the whole of them originated and was completed by individuals without the aſſiſtance of the ſtate. See alſo the names of the ſeveral canals, rivers, &c. for further information.

INLAYING. See Veneering, Mosaic, and Marquetry.

INLEASED, in our *Old Writers*, ſignifies entangled or enſnared. It is uſed in the champion's oath. 2 Inſt. 247. Blount.

INLETS, *Bay of*, in *Geography*, a bay on the coaſt of New Holland, ſo called by Cook, in June 1770, lying between cape Palmerſton and cape Townſhend.

INLI, a town of Corea; 45 miles W. of Hoang-tcheou.

INLISTING, in a *Military Senſe*. See Listing.

INMATES, ſuch perſons as are admitted, for their money, to live in the ſame houſe or cottage with another man, in different rooms, but going in at the ſame door; being uſually ſuppoſed to be poor, and not able to maintain a whole houſe themſelves. Theſe are inquirable in a court-leet.

No owner or occupier of a cottage ſhall ſuffer any inmates therein, or more families than one to inhabit there, on pain of forfeiting 10*s*. per month to the lord of the leet.

INN, in *Geography*, a river which riſes in the country of the Griſons, about 12 miles S.W. of Zuls, and runs into the Danube near Paſſau.—Alſo, a river of Auſtria, which runs into the Danube near Efferding.

Inn, a place appointed for the entertainment and relief of travellers.

Inns are licenſed and regulated by juſtices of the peace, who oblige the landlord to enter into recognizances for keeping good order. See Alehouses.

If a perſon who keeps a common inn refuſes to receive a traveller into his houſe as a gueſt, or to find him victuals and lodging, on his tendering him a reaſonable price for them, he is liable to an action of damages, and may be indicted and fined at the king's ſuit. (1 Ventr. 333.) By the yearly acts againſt mutiny and deſertion, the conſtable, and in his default a juſtice of the peace, may quarter ſoldiers in inns, livery-ſtables, ale-houſes, and victualling-houſes. The rates of all commodities ſold by innkeepers, according to our ancient laws, may be aſſeſſed; and innkeepers not ſelling their hay, oats, beans, &c. and all manner of victuals, at reaſonable prices, without taking any thing for litter, may be fined and impriſoned, &c. by 21 Jac. I. c. 21. Where an innkeeper harbours thieves, perſons of infamous character, or ſuffers any diſorders in his houſe, or ſets up a new inn where there is no need of one, to the hindrance of ancient well governed inns, he is indictable and fineable; and by ſtatutes ſuch inn may be ſuppreſſed. (1 Hawk. P. C. 225.) Action upon the caſe lies againſt any innkeeper, if a theft be committed upon his gueſt by a ſervant of the inn, or any other perſon not belonging to the gueſt; though it is otherwiſe where the gueſt is not a traveller, but one of the ſame town or village; for in that caſe the innkeeper is not chargeable; nor is the maſter of a private tavern anſwerable for a robbery committed on his gueſt. It is ſaid that even though the travelling gueſt does not deliver his goods, &c. into the innkeeper's poſſeſſion, yet if they are ſtolen he is chargeable. An innkeeper is not chargeable for any thing out of his inn, but only for what is within it; yet where he of his own accord puts the gueſt's horſe to graſs, and the horſe is ſtolen, he is anſwerable; he not having the gueſt's orders for putting ſuch horſe to graſs. The innkeeper may juſtify ſtopping the horſe, or other things of his gueſt, for his reckoning; and may detain the ſame until it be paid. Where a perſon brings his horſe to an inn and leaves him in the ſtable, the innkeeper may detain him until ſuch time as the owner pay for his keeping; and if the horſe eats out as much as he is worth, after a reaſonable appraiſement made, he may ſell the horſe and pay himſelf. But when a gueſt brings ſeveral horſes to an inn, and afterwards takes them all away, excepting one, this horſe ſo left may not be ſold for payment of the debt of others; for every horſe is to be ſold, only to make ſatisfaction for what is due for his own meat.

Any perſon found tippling in an inn, is adjudged within the ſtatutes againſt drunkenneſs; and innkeepers, or alehouſe-keepers, permitting tippling in their houſes, are liable to the penalty of 10*s.* &c. by 1 Jac. cap. 9. 1 Car. cap. 4. 21 Jac. cap. 7.

Inns. Our colleges of municipal or common law profeſſors and ſtudents, are called inns: the old Engliſh word for houſes of noblemen, biſhops, and others of extraordinary note, being of the ſame ſignification with the French word *hotel.*

Inns *of Court* are ſo called, as ſome think, becauſe the ſtudents there are to ſerve and attend the courts of judicature; or elſe, becauſe anciently theſe colleges received none but the ſons of noblemen, and better ſort of gentlemen, who were there to be qualified to ſerve the king in his court; as Forteſcue affirms. And in his time he ſays, there were about two thouſand ſtudents in the inns of court and chancery, all of whom were *filii nobilium*, or gentlemen born. But this cuſtom has gradually fallen into diſuſe; ſo that in the reign of queen Elizabeth, ſir Edward Coke does not reckon above a thouſand ſtudents, and the number at preſent is very conſiderably leſs; for which judge Blackſtone aſſigns the following reaſons: 1. Becauſe the inns of chancery being now almoſt totally filled by the inferior branches of the profeſſion, are neither commodious nor proper for the reſort of gentlemen of any rank or figure; ſo that there are very rarely any young ſtudents entered at the inns of chancery. 2. Becauſe in the inns of court all ſorts of regimen and academical ſuperintendence, either with regard to morals or ſtudies, are found impracticable, and therefore entirely neglected. Laſtly, becauſe perſons of birth and fortune, after having finiſhed their uſual courſes at the univerſities, have ſeldom leiſure or reſolution ſufficient to enter upon a new ſcheme of ſtudy at a new place of inſtruction; wherefore few gentlemen now reſort to the inns of court, but ſuch for whom the knowledge of practice is abſolutely neceſſary in ſuch as are intended for the profeſſion. Comm. book i. p. 25.

Our inns of court, juſtly famed for the production of men of learning in the law, are governed by maſters, principals, benchers, ſtewards, and other officers; and have public halls for exerciſes, readings, &c. which the ſtudents are obliged to attend, and perform for a certain number of years, before they can be admitted to plead at the bar. Theſe ſocieties have not, however, any judicial authority over their members; but inſtead of this they have certain orders among themſelves, which have by conſent the force of laws. For lighter offences perſons are only excommoned, or put out of commons; for greater, they loſe their chambers, and are expelled the college; and when once expelled out of one ſociety, they are never received by any of the others. The gentlemen in theſe ſocieties may be divided into benchers, outer-barriſters, inner-barriſters, and ſtudents.

The four principal inns of court, are the Inner Temple, and Middle Temple, heretofore the dwelling of the Knights Templars, purchaſed by ſome profeſſors of the common law about three hundred years ago; Lincoln's Inn and Gray's Inn, anciently belonging to the earls of Lincoln and Gray. The other inns are the two Serjeants Inns

Inns *of Chancery* were probably ſo called, becauſe anciently inhabited by ſuch clerks as chiefly ſtudied the forming of writs which regularly belonged to the curſitors, who are officers of chancery.

The firſt of theſe is Thavies Inn, begun in the reign of Edward III. and ſince purchaſed by the ſociety of Lincoln's Inn. Beſides this we have New Inn, Symond's Inn, Clement's Inn; Clifford's Inn, anciently the houſe of lord Clifford; Staple's Inn, belonging to the merchants of the ſtaple; Lion's Inn, anciently a common inn with the ſign of the lion; Furnival's Inn, and Bernard's Inn.

Theſe were heretofore preparatory colleges for younger ſtudents; and many were entered here before they were admitted into the inns of court. Now they are moſtly taken up by attornies, ſolicitors, &c.

They all belong to ſome of the inns of court, who formerly uſed to ſend yearly ſome of their barriſters to read to them.

Inn, or *Inner*, in the *Manege*, is applied differently, according as the horſe works to the right or left upon the volts, or as he works along by a wall, a hedge, or the like. For along or by a wall, the leg that is of a ſide with, or next the wall, is the outer, and the other the *in* or *inner* leg. And if upon volts, the horſe works to the right, the right heel is the inner, and the left the outer heel, and ſo of the other parts of the body, furniture, &c. The direct contrary of this will happen, if the horſe works to the left.

INNATE Air. See Air.

Innate *Force.* See Vis *Inſita.*

Innate *Heat.* See Heat.

Innate *Ideas*, or *Principles*, are certain primary notes or characters, by many ſuppoſed to be ſtamped on the mind of man when it firſt receives its being, and which it brings into the world with it.

But the doctrine of innate ideas is abundantly confuted by Mr. Locke. See Idea.

Innate, in *Natural Hiſtory*, particularly in that branch of it which treats of foſſil remains or reliquia, is applied to ſuch parts of the animal bodies as have been produced independently of any effort of the animal, and are either internal parts, as the bones, which often give the form to extraneous foſſils, or external parts, as the ſcales and fins of fiſh, the horny covering in ſome of the amphibia, and the integument which incloſes the whole of the body in inſects, all of which are ſometimes found in a foſſil ſtate, as Mr. William Martin obſerves in his "Outlines," p. 86. The genera of reliquia which do not depend on innate parts, but on fabricated parts of the animal parts, which are ſuperadded to the body by ſome voluntary effort of the animal, are called conchyliolithus and eriſmatolithus.

INNER Barrister. See Barrister.

Inner *Poſt*, is an additional piece of oak timber brought on to the foreſide of the main poſt upon which the tranſoms are let on or ſeated; it adds to the ſecurity of the planks, as the main poſt is ſeldom ſufficient before the rabbit for that purpoſe, and greatly ſtrengthens the ſtern or main poſt.

Inner *See*, in *Geography*, a river which riſes about five miles N.W. of Goſlar, and runs into the Leine, in the biſhopric of Hildeſheim.

Inner *Sound*, a ſtrait of the North ſea, between the iſle of Skye, and the N.W. coaſt of Inverneſsſhire, in Scotland.

INNERSHON, a ſmall iſland on the weſt ſide of the gulf of Bothnia. N. lat. 61° 34′. E. long. 17° 6′.

INNICHEN, a town of Germany, in the Tyroleſe ſituated near the Drave; anciently called "Aguntum;" 29 miles E. of Brixen. N. lat. 46° 41′. E. long. 12° 20′.

INNINGS, lands recovered from the ſea, by draining and banking.

INNITPOUR, in *Geography*, a town of Bengal; 48 miles N. of Dacca.

INNO, *Ital.* a hymn, or ſpiritual ſong.

INNOCENT I. pope, in *Biography*, was a native of Albano, and was unanimouſly elected to the popedom by the clergy and people, on the death of Anaſtaſius in the year 402. He obtained from the emperor new and ſevere laws againſt the Donatiſts, in conſequence of which that ſect was cruelly perſecuted, and thoſe who refuſed to return to the boſom of the Catholic church were puniſhed with fines, baniſhment, the confiſcation of goods, and in ſome inſtances with death. He eſpouſed the cauſe of Chryſoſtom, and even refuſed to hold communion with the eaſtern churches, on account of their treatment of that eminent man. He was the firſt who perſecuted the Novatians at Rome, by depriving them of their churches, and preventing their aſſembling in public, for religious worſhip; the Pelagians came likewiſe under his laſh; he declared them not only unworthy of Chriſtian communion, but of human ſociety, and even of life. He died in the year 417, after having preſided over the church about fifteen years. He was a perſon of great addreſs, and a lively genius, and was well acquainted with the traditions of the church. His decretals ſufficiently ſhew his uſurping and domineering ſpirit, and his wiſhes to make the Chriſtian world ſubmit to his inſolence; they have been frequently quoted by the advocates of the ſee of Rome, to demonſtrate how early the popes claimed, as the ſucceſſors of St. Peter, an univerſal authority and juriſdiction. Thirty-four letters, in the firſt volume of the "Letters of the Popes" have been attributed to this pontiff, but by many of the ableſt critics the greater part of them has been regarded as ſuppoſititious.

Innocent II. pope, a deſcendant from a noble family at Rome, aſcended the papal throne in the year 1130. He had already filled ſome reſpectable offices in the church, and is ſaid to have led a moſt exemplary life from his infancy, and to have been diſtinguiſhed for eminent abilities and ſtrict probity, while he was at the ſame time of a moſt humane and courteous diſpoſition. He was promoted to the ſacred college by the title of cardinal St. Angelo, and was employed by ſeveral of the popes in important negociations at home and abroad. Upon the death of Honorius II. he was elected his ſucceſſor by a part only of the conclave, the reſt chooſing Peter de Leon, the ſon of a Jew, who took the name of Anacletus II., and was acknowledged by the kings of Scotland and Sicily, while Innocent was received by the other princes of Europe. Being driven from Italy, he fled to France, where he held ſeveral councils, at one of which he thundered out a ſentence of excommunication againſt Anacletus, and all his adherents. He crowned the emperor Lotharius with great ſolemnity, and for the ſupport of his new dignity granted to him, to his daughter, and to his ſon-in-law, during their lives, all the eſtates of the counteſs Matilda. On the death of his rival, another pope was choſen by the ſame party, who took the name of Victor, but who, probably, feeling himſelf unequal to contend with the power of Innocent, threw himſelf at the feet of the pontiff, and thus put an end to the ſchiſm in the church. Innocent, having now no enemy to diſturb his peace, took up his reſidence at Rome, and ſummoned a general council to meet in the Lateran in the year 1139. This was the moſt numerous council that had ever been held, conſiſting, it is reported, of a thouſand biſhops, beſides a crowd of abbots and other eccleſiaſtics, who, beſides other buſineſs, declared the ordinations of Anacletus null; excommunicated Roger, king of Sicily, and condemned the opinions of the famous Arnold of Breſcia. Innocent, after this, was not contented with the pacific duties of his office, but actually marched in perſon, with his army, againſt the prince who ſeemed to ſet at his defiance the ſentence of excommunication. Roger was too well ſkilled in military tactics to leave the event of the conteſt doubtful, he attacked the epiſcopal army, which he put to flight, and was ſo completely ſucceſsful, as to take the holy pontiff priſoner, with ſeveral cardinals, and other perſons of diſtinction. When Innocent was conducted into the king's camp, he found, what he little expected, that he had fallen into the hands of a generous enemy; the victorious king ſent ſome of his principal officers to beg his holineſs's pardon, and to aſſure him he was ready to enter into an accommodation upon the terms which he had formerly offered by his deputies. Innocent readily acceded: the terms were drawn up and executed, in conſequence of which the pope abſolved Roger from excommunication, and ſolemnly inveſted him with the kingdom of Sicily, the dukedom of Apulia, and the principality of Capua; while, on the other hand, the king acknowledged Innocent for lawful pope, and engaged to aſſiſt him whenever his aid ſhould be required. Upon the recovery of his liberty Innocent returned to Rome, but the remainder of his life was ſpent in much diſquiet. The laſt two years of his life were wholly occupied in reducing ſeveral cities which attempted to ſhake off the yoke of the apoſtolic ſee, and to recover their ancient liberty. The Romans alſo refuſed to obey him as their prince, reſtored their ſenate, and created their own magiſtrates. In the midſt of theſe calamities the pope fell ſick, and died in 1143, after a pontificate of nearly fourteen years. In private life he was moſt highly eſteemed on account of the ſuavity of his manners, but from the ſeveral revolts which took place while he was head of the church, it has been ſuſpected that his adminiſtration of government was not conducted with prudence and wiſdom, and that his zeal for exalting the papal pretenſions was not behind that of any of his predeceſſors. Forty-three of his letters are inſerted in the tenth volume of the Collect. Concil.

Innocent III. pope, originally called Lotharius, was a deſcendant from the illuſtrious houſe of the counts of Segni, and born at Anagni about the year 1161. After purſuing his ſtudies at Rome, he went to the univerſity of Paris, where he was admitted to the degree of doctor. From this period he was advanced very rapidly in the church; was ordained ſub-deacon by Gregory VIII., and preferred to the dignity of cardinal-deacon by Clement III., under the title of cardinal St. Sergius, and St. Bacchius. On the death of pope Celeſtine III. in the year 1198, Lotharius was elected his ſucceſſor, being then only in his thirty-ſeventh year. Being at this period only in deacon's orders, he was firſt ordained prieſt, in order to his being able to undertake the high office of pope, when he aſſumed the name of Innocent III. From the moment of his exaltation, he ſeems to have ſet before him, as objects for his imitation, the character and conduct of pope Gregory VII., and with equal intrepidity and addreſs, purſued his plans of ambition, till he arrived at a height of deſpotiſm, which the world beheld with wonder and aſtoniſhment, but to which the ſtates of Europe ſubmitted with a ſilence that was highly diſgraceful to them. "Under this young and ambitious prieſt," ſays Gibbon, "the ſucceſſors of St. Peter attained the full meridian of their greatneſs; and in a reign of eighteen years, he exerciſed a deſpotic command over the emperors and kings whom he raiſed and depoſed; over the nations, whom an interdict of months or years deprived, for the offence of their rulers, of the exerciſe of Chriſtian worſhip. In the council of the Lateran he acted as the eccleſiaſtical, almoſt as the temporal, ſovereign of the Eaſt and Weſt. It was at the feet of this legate that John of England ſurrendered his crown; and Innocent may boaſt of the two moſt ſignal triumphs over ſenſe and humanity, the eſtabliſhment of tranſubſtantiation, and the origin of the inquiſition. At his voice, two cruſades, the fourth and the fifth, were undertaken; but except a king of Hungary, the princes of the ſecond order were at the head of the pilgrims; the forces were inadequate to the deſign; nor did the effects correſpond with the hopes and wiſhes of the pope and the people." Innocent did not confine his efforts to the Holy Land, he promoted a cruſade againſt the Albigenſes. He firſt attempted to convert them by his miſſionaries, one of whom was murdered, which was the ſignal for the diſplay of all his wrath; he did not even deign to inſtitute an inquiry, but ordered the whole race to be purſued with fire and ſword, and to be treated with more ſeverity than the Saracens themſelves. Immenſe numbers of lives were ſacrificed in his holy war, and barbarities practiſed, before unheard of; but the perpetrators of them were applauded and rewarded by the cruel pontiff, and the infernal ſpirit by which they had been actuated was impiouſly called zeal in ſupporting the cauſe of God and of the church. In 1215, the fourth general Lateran council was held at Rome, which was ſo managed by the all-controlling power of the pontiff, that inſtead of exerciſing the functions of a deliberative body, it was made uſe of only as an inſtrument to regiſter canons and decrees which Innocent had drawn up, and which he permitted to be read for their approbation. In this council a ſentence, which had been pronounced ſome time before, ſuſpending Stephen Langton, archbiſhop of Canterbury, was confirmed. The pope, likewiſe, thundered out a ſentence of excommunication againſt the barons, which they treated with merited contempt, and bravely perſiſted in defending thoſe privileges, the charters of which they had lately compelled their monarch to ſign. In the year 1216, Innocent undertook a journey to Piſa; but on his arrival at Perugia he was attacked with a violent diſorder, which put an end to his life in a few days. According to Mr. Berington, "Innocent was learned, magnificent, perſeverant, wiſe. In the knowledge of laws and politics he had no equal: he poſſeſſed the art of government, and was obeyed more from fear than love. Ambition was his ruling paſſion, to gratify which, he overſtepped the bounds of decency and juſtice, playing as wantonly with the ſolemn cenſures of the church as if they had been inſtituted for the common purpoſes of wayward caprice or reſentful vengeance. To look into him for the amiable virtues of life, or for thoſe which ſhould form the paſtoral character, would be loſs of time. The prerogative of the holy ſee, built up by adulation and miſjudging zeal, filled his mind; its aggrandizement he ſought ſometimes, perhaps, from motives which the cool reaſoner may excuſe; and the meteor of univerſal empire gleaming on his ſenſes, did not permit the operation of a diſpaſſionate and unbiaſſed judgment. No tears were ſhed when Innocent fell, but thoſe which Religion wept, too juſtly pained by the inordinate exertions and worldly views of her firſt miniſter." Innocent was the author of a variety of works, which are enumerated by Dupin, but the moſt valuable are his "Epiſtles," which threw conſiderable light on the eccleſiaſtical hiſtory of his time. His works have been collected in two volumes folio; the beſt edition is that publiſhed at Paris in 1682.

INNOCENT IV., pope, was a native of Genoa, and being diſtinguiſhed for his learning and attainments, he was in early life made canon of Parma, from which he was promoted to the chancellorſhip of the Roman church. In 1227 he was raiſed to the purple by Gregory IX., and in 1243 he was elevated to the papal throne, when he took the name of Innocent IV. Previouſly to this he was on terms of ſtrict intimacy with the emperor Frederic II., who had been engaged in a conteſt with the court of Rome, and that prince no ſooner received the news of his exaltation, than he ſent a ſplendid embaſſy to congratulate him upon his election, and to aſſure him that nothing ſhould be wanting to re-eſtabliſh harmony between the church and the empire. The pope, however, began to aſſume a dignity inconſiſtent with friendſhip, and he plainly declared that he was reſolved to maintain the higheſt pretenſions of the apoſtolical ſee. Legates were diſpatched to accommodate all differences, but it was of no avail, and hopes of reconciliation being at an end, Frederic prepared to reduce the pope to reaſon by the terror of his arms. Innocent, unable to reſiſt the power of the emperor, fled for protection to his native city, where he was received with every mark of diſtinction. Here he aſſembled a council, conſiſting of about 140 prelates, ſome princes, and the ambaſſadors of moſt of the crowned heads in Europe; he laid before this auguſt aſſembly the motives which induced him to call them together, deſcribing the emperor as a tyrant, a perſecutor of the church, and as guilty of hereſy, ſacrilege, and other grievous crimes. The council gave credit to the pontiff, and ſanctioned the ſentence of excommunication pronounced againſt him. This led to a moſt deſtructive war, which was carried on in Germany and Italy till the death of the emperor Frederic in 1250, who was ſucceeded by his eldeſt ſon Conrad, who took up his father's cauſe with ſo much zeal and intrepidity, as rendered Innocent fully ſenſible of his inability to withſtand that prince with his own forces only. He accordingly made many unſucceſsful attempts for obtaining aſſiſtance, and his army was defeated, which ſo affected the pontiff, that he fell ſick and died in the month of December 1254, after he had preſided over the church nearly twelve years. He had high notions reſpecting the power and authority of the papal ſee: he poſſeſſed conſiderable learning; was well acquainted with the divinity of the times, and was regarded as the beſt civilian of his age. He was author of a work entitled "Apparatus, Libris quinque diſtinctus, in totidem Libros Decretalium," firſt printed at Venice in 1570; and of ſeveral other pieces, beſides twenty letters, which are inſerted in the eleventh volume of the Collect. Concil. He was not only learned, but a great encourager of learning, and is ſaid to have been the firſt who gave red hats to the cardinals.

INNOCENT V., pope, was born at a town on the Iſere, in Burgundy. When very young he entered the Dominican order of preaching friars, and purſued his ſtudies in divinity with ſo much ſucceſs, that he was appointed to fill the theological chair in the univerſity of that city, and was conſidered as one of the moſt learned divines of the age. He obtained conſiderable preferment in the church, and about 1271 was nominated by pope Gregory X. archbiſhop of Lyons, and ſoon afterwards was promoted to the ſacred college by the title of cardinal biſhop of Oſtia. On the death of Gregory he was unanimouſly choſen his ſucceſſor in the papal dignity, and took the name of Innocent V. Beſides reconciling thoſe ſtates of Italy which were carrying on the moſt bloody wars againſt each other under the oppoſite denominations of Guelphs and Gibellines, and bringing about a peace between the republics of Lucca and Piſa, he projected the miſſion of a ſplendid legation into the Eaſt, to obtain from the emperor, Michael Palæologus, the confirmation of the articles of union, but he died before he could carry his deſign into execution, after a ſhort pontificate of about five months. He wrote "Commentaries" upon the Pentateuch, the Canticles, and the Goſpels: "Notes on the Epiſtles of St. Paul," and other pieces, which have been publiſhed ſince his death.

INNOCENT VI., pope, formerly called Stephen Aubert, was brought up to the ſtudy and practice of the law, and in 1335 he was profeſſor of the civil-law at Toulouſe, and chief judge of that city. In two years after we find him biſhop of Noyon, and in 1340 he was tranſlated to the ſee of Clermont. In 1342 he was raiſed by pope Clement VI. to the dignity of cardinal biſhop of Oſtia, and at the ſame time appointed grand penitentiary of the Romiſh church. In 1352 he was unanimouſly choſen pope, and took the name of Innocent VI. He made it his buſineſs to correct abuſes, and alſo aboliſhed the heavy impoſitions laid upon the clergy, when preferred to any new benefice or dignity. He retrenched all the unneceſſary expences of the papal court, contenting himſelf even with a ſmall number of attendants: he obliged the cardinals to follow his example, urging them to beſtow the ſuperabundance of their wealth in relieving the neceſſities of the poor. Innocent maintained the decrees of his predeceſſors againſt thoſe Minorite friars who aſſumed the title of "Spiritual Brethren," and who contended againſt the right of the clergy poſſeſſing any property. Two of this deſcription were arreſted at Montpelier in the year 1354; the pope attempted to convert them from the error of their ways, but finding them obſtinate, he gave them up to the inquiſitors to be burnt alive. In the following year he ſent a legate a latere to Rome to crown Charles, king of Germany, and his queen Anne with the imperial crown, but not before that prince had ſubſcribed to the moſt humiliating conditions. After this, nothing occurs during the remainder of Innocent's pontificate which requires to be noticed. He died at Avignon in 1362, after he had filled the papal chair nearly ten years. He has been highly commended for his probity and the ſanctity of his life: he was generous to the wants of the poor: an enemy to vice, the patron and protector of virtue in every condition of life. He left behind him many epiſtles, ſome of which have been printed, and others are preſerved in the Vatican.

Innocent VII., pope, was born at Salmona, in Abruzzo, about the year 1339, obtained a high reputation for his knowledge of the civil and canon law, was made clerk of the apoſtolic chamber by pope Urban VI., and was afterwards employed to collect the revenues of the apoſtolic ſee of England. As a reward for his ſervices in thoſe ſituations he obtained conſiderable church preferment, and was at length raiſed to the ſacred college under the title of cardinal preſbyter of Santa Croce. On the death of Boniface IX. he was choſen to the popedom, and took the name of Innocent VII. Scarcely had he been conſecrated, when a dreadful tumult broke out in Rome between the Gibellines and the Guelphs: this led to other diſturbances, which laſted during the pontificate of Innocent, who died in about two years after his elevation. He is repreſented as of a mild and pacific diſpoſition; of a generous and beneficent temper; an enemy to all pomp and ſhow; free from pride and ambition, and of great addreſs in ſtate affairs. He is much blamed for having been the occaſion of elevating unworthy perſons to the higheſt poſts of dignity and truſt. He is author of a diſcourſe "On Church Union," and ſome "Letters."

Innocent VIII., pope, was born at Genoa in the year 1432: at an early age he was ſent to the court of Naples, where he lived ſeveral years during the reigns of Alphonſo and his ſon Ferdinand, and received ſubſtantial marks of favour from both princes. After this he removed to Rome, and obtained conſiderable church preferment, till at length he was raiſed to the purple by the title of cardinal of St. Balbina in the year 1473. Upon the death of Sixtus IV. in 1484, he was elected his ſucceſſor, and took the name of Innocent VIII., having been previouſly known by that of John Baptiſt Cibo. As ſoon as he was ſeated in his government, he attempted to procure another cruſade, but without ſucceſs. His efforts, however, contributed to bring much wealth into the apoſtolic treaſury, part of which the pope appropriated to his own uſe; and the reſt he expended on the repair of ancient works of art, or in ſupport of a war in which he ſoon became involved with Ferdinand, king of Naples. Innocent ſpent the concluding years of his pontificate in endeavouring to maintain order and good government in the church, and in cultivating the arts of peace. He cleared the country of robbers and aſſaſſins, with which it was at that time much infeſted; adopted meaſures for the regular ſupply of Rome with proviſions, and adorned it with many magnificent buildings. He died in the year 1492, aged 60, after he had filled the papal throne nearly eight years. He was poſſeſſed of a very moderate ſhare of learning and talents, but ſecured the attachment of all ranks by the ſweetneſs of his temper and the gentleneſs of his manner. His character, in a moral point of view, will not bear examination: he unbluſhingly acknowledged himſelf the father of a numerous progeny of natural children, and is ſaid to have been the firſt of the popes who introduced that new and extraordinary proceeding of owning publicly his ſpurious iſſue, heaping upon them riches without meaſure. He left behind him ſome letters, and one to Henry VII., king of England, againſt citing the clerical orders before ſecular tribunals.

Innocent IX., pope, known originally under the name of John-Anthony-Facchinetti, was born at Bologna in the year 1519, where he received his education, and was admitted to the degree of doctor in 1544. He now became a domeſtic in the family of cardinal Farneſe, who ſent him in the capacity of vicar to Avignon, and again to Parma. In 1566, he was ſent by Pius V. as nuncio to Venice, where he had a principal concern in eſtabliſhing the confederacy between the pope, the king of Spain, and the republic againſt the Turks. After this he was created patriarch of Jeruſalem, preſident of the inquiſition, and cardinal. In 1591, he was unanimouſly elected to the popedom, when he took the name of Innocent IX. He immediately projected grand plans of improvement, of an eccleſiaſtical and economical nature, none of which did he live to execute. He died in the ſecond month of his pontificate, at the age of ſeventy-two.

Innocent X., pope, was born at Rome about the year 1575, where he was educated and brought up to the profeſſion of the civil law, of which he was admitted doctor when he was only in his twentieth year. He obtained many inſtances of preferment in the church, and, in 1627, a cardinal's hat was preſented to him by pope Urban VIII. He was next made prefect of the eccleſiaſtical immunities, ſupreme judge of the inquiſition, and protector of the kingdom of Poland. On the death of Urban he was elected pope; he had already carried on an illicit commerce with his brother's widow, Donna Olympia Maldachini, to whom he now abandoned himſelf, the adminiſtration of his temporal affairs, and the government of the church. All benefices, all employments, whether eccleſiaſtical, civil, or military, were diſpoſed of by her to the higheſt bidders, without any regard to friendſhip or merit, or to the character of the purchaſers. She induced the pope to forget all ſenſe of right and wrong when it interfered with her wiſhes. In 1645, upon the application of the Dominicans, who were aſſociated with the Jeſuits in the miſſion to China, Innocent condemned the indulgence which the Jeſuits had ſhewn to the Chineſe ſuperſtitions. The moſt remarkable tranſaction of his pontificate, was his condemning, by a bull, in the year 1653, the five propoſitions ſelected by the Jeſuits from Janſenius's "Auguſtinus." He died in 1655, about the age of eighty-one, having filled the papal throne little more than ten years.

Innocent XI. was born at Como, in the duchy of Milan, in the year 1611. He was the ſon of a rich banker, and his firſt profeſſion was that of a ſoldier, in which he diſtinguiſhed himſelf by his gallantry. Quitting the military character he embraced the eccleſiaſtical profeſſion, and went to ſtudy at Naples, where he was admitted to the degree of doctor. Having filled, with high reputation, ſeveral offices in the church, he was raiſed to the purple in 1645, and, in 1678, he was elected to the popedom. He began his high career with aboliſhing abuſes, and ſuppreſſing many groſs ſuperſtitions then prevailing in the church of Rome. He likewiſe attempted, by wiſe inſtitutions and judicious regulations, to reform the manners of the clergy, and to ſtem the torrent of licentious morals among the laity. In 1677, he ſuppreſſed "the right of aſylum," enjoyed by foreign miniſters at Rome, extending much farther than their palaces, the immunities of which it was not deſigned to violate. Moſt of the ambaſſadors from foreign courts readily acquieſced, but the miniſter from the court of France refuſed to ſubmit to it, and the pope, unwilling to enter into a conteſt with Lewis XIV., allowed his ambaſſador to enjoy his ancient privileges. He had now a conteſt with the French king, about the right of diſpoſing of benefices and church lands claimed by that monarch, and confirmed to him by an aſſembly of the clergy, which nearly terminated in a ſeparation of the Gallican church from the Roman communion. It was on this occaſion that Lewis ſummoned the famous aſſembly of biſhops, which met at Paris in the year 1682, and drew up the four celebrated propoſitions declaring the power of the pope to be merely ſpiritual, and inferior to that of a general council, and maintaining the inviolability of the rules, inſtitutions, and obſervances of the Gallican church. Innocent died in 1689, having preſided over the Roman ſee twelve years and a half. He was virtuous and pious, but without pretenſions to learning. His zeal for the reformation of abuſes, the improvement of morals, and the reſtoration of church diſcipline, has given him a rank among the beſt of the popes.

Innocent XII., pope, originally named Anthony Pignatelli, was deſcended from an illuſtrious family at Naples, and born there in the year 1615, and ſucceeded to the popedom in 1691, as ſucceſſor to Alexander the VIIIth. In imitation of the example of pope Innocent XI. he applied himſelf to the reformation of the church and court of Rome. He was unwearied in his endeavours to reform the corrupt manners of the clergy, which were not wholly unſucceſsful, though he found that the entire accompliſhment of the Herculean taſk was a conſummation, which all his prudence and reſolution were unable to effect. He was anxiouſly devoted to the intereſts of the poor, and the wealth which many of his predeceſſors had been accuſtomed to accumulate, or to beſtow on worthleſs relatives, he devoted to the public benefit, employing it in the erection of hoſpitals, and other uſeful inſtitutions, and particularly in the improvement of the ports of Anzio and Nettuno. Innocent died in the year 1700, at the advanced age of eighty-five, after preſiding over the church about nine years. He had rendered himſelf univerſally reſpected by his talents, and beloved on account of his many virtues.

Innocent XIII., pope, formerly named Michael-Angelo Conti, ſon of Charles Conti, duke of Poli, was born at Rome in the year 1655. He roſe ſucceſſively to the higheſt offices in the church, till at length he was elected ſucceſſor to Clement XI., in the papal dignity, in the year 1721. He died in 1724, leaving behind him a character for great wiſdom, virtue, and learning. When a cardinal he diſtinguiſhed himſelf above moſt of the members of the ſacred college; but the infirmities to which he had been ſome years ſubject, prevented him from diſtinguiſhing his pontificate by any actions which are worthy of being recorded. As authorities for the foregoing articles, ſee Bower's Hiſt. of the Popes; Moreri, Gibbon, &c.

INNOCENTS Day, the name of a feaſt celebrated on the twenty-eighth day of December, in commemoration of the infants murdered by Herod.

Heretofore it was the cuſtom to have dances in the churches on this day, wherein were perſons, who repreſented biſhops, by way of deriſion, as ſome ſuggeſt, of the epiſcopal dignity; though others, with more probability, ſuppoſe it done in honour of the innocence of childhood. See Episcopus *puerorum*.

By a canon of the council of Cognac, held in 1260, theſe were expreſsly forbidden; but they were not wholly ſuppreſſed, at leaſt in France, before the year 1444, when the doctors of the Sorbonne addreſſed a ſpirited letter on this ſubject to all the biſhops of the kingdom.

INNOMINATA Arteria, in *Anatomy*, the firſt large trunk ſent off from the arch of the aorta. See Artery.

Innominata *glandula*, the lachrymal gland. See Eye.

INNOMINATI, *Gli Innominati*, *Anonymi*, perſons who have no names, a title by which the academiſts of Parma diſtinguiſh themſelves.

Moſt cities in Italy have an academy, and each has its proper name. Thus thoſe at Parma entitle themſelves Gli innominati, as if it was their character to have no name at all.

INNOMINATUM, Os, in *Anatomy*, the large bone compoſing the chief part of the ſides of the pelvis, and receiving the articulation of the lower extremity. See Extremities.

INNOVATION, in *Law*. See Novation.

INNUENDO, of *innuo*, *I nod*, or *beckon*, is a word frequently uſed in writs, declarations, and pleadings, to aſcertain a perſon or thing which was named, but left doubtful, before: as, he (*innuendo* the plaintiff) did ſo and ſo; mention being before made of another perſon. In common obſervation or writing, an *innuendo* denotes an oblique hint, or diſtant reference; in contradiſtinction to a direct and poſitive charge.

INNY, in *Geography*, the name of two rivers in Ireland; one which riſes in the county of Weſtmeath, and having paſſed through Loughs Derveragh and Iron, forms a boundary between this county and Longford, for ſeveral miles, after which it croſſes the ſouthern part of the latter, and flows into Lough Ree, an expanſe of the Shannon; the other is a mountain ſtream in the barony of Iveragh, Kerry, which empties itſelf into Ballin Skelig's bay.

INOCARPUS, in *Botany*, from ις, ινος, *a fibre*, or *nerve*, and καρπος, *a fruit*, becauſe the drupa of this genus is compoſed of fibres or nerves. Schreb. 297. Forſter. Gen. 35. Linn. Suppl. 35. Thunb. Nov. Gen. 45. Willd. Sp. Pl. v. 2. 624. Mart. Mill. Dict. v. 2. Juſſ. 152. Lamarck Dict. v. 3. 253. Illuſtr. t. 362. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Dumoſæ*, Linn. *Sapotæ*, Juſſ.

Gen. Ch. *Cal.* Perianth of one leaf (campanulate, according to Thunberg) in two, roundiſh, nearly equal ſegments. *Cor.* of one petal, tubular; tube cylindrical, longer than the calyx; limb longer than the tube, divided into five, linear, acute, undulated, often reflexed ſegments. *Stam.* Filaments ten, very ſhort, inſerted into the tube; the lower ones alternate; anthers ovate, twin, erect. *Piſt.* Germen oblong, hairy, ſuperior; ſtyle none; ſtigma a hollow point. *Peric.* Drupa ovate, incurved, compreſſed, large, ſingle-ſeeded. *Seed.* A nut compoſed of woody fibres; kernel oval, compreſſed.

Eſſ. Ch. Calyx bifid. Corolla funnel-ſhaped. Stamens in a double row. Drupa ſingle-ſeeded.

1. I. *edulis*. Willd. Sp. Pl. v. 2. 624. (Gujanus; Rumph. Amboin. v. 1. 170. t. 65.) A native of the Society, Friendly,

and New Hebrides Iſlands, in the South ſeas, and alſo of Amboina. Forſter deſcribes this as a lofty *tree*, having a *trunk* as thick as a man's body, with a brown chinky *bark*. *Branches* woody, ſpreading, variouſly divided. *Leaves* ovate-oblong, ſcarcely cordate, netted with abundance of veins. *Flowers* duſky white, ſcarcely half an inch in length. From Cook's laſt voyage we learn, that the nuts of *Inocarpus* are called *E—iſi*. The kernel of theſe, which is kidney-ſhaped, and about an inch in diameter, is eaten roaſted by the natives. It is ſweetiſh, but leſs pleaſant than the cheſnut, harder, and not ſo farinaceous. The bark is aſtringent, and uſed in the dyſentery. In New Guinea, they ſmear their arrows with the expreſſed reſinous juice.

INOCULATING, in *Gardening*, the art or practice of inſerting the buds of trees of the ſame kind into their ſtocks or other parts. It is a ſort of grafting which is often had recourſe to in the ſummer ſeaſon for raiſing different kinds of trees and plants, as it frequently ſucceeds better than that of the common method. It is uſually executed in the manner deſcribed below. A ſharp knife, with a flat haft for the purpoſe, and proper cuttings of the trees deſigned to be propagated being provided, a choice ſhould be made of a ſmooth part of the ſtock which is to be inoculated; five or ſix inches from the ground, where intended to be dwarf, but when for a ſtandard at the height of five and a half or ſix feet; and a horizontal cut made acroſs the rind of the ſtock, as well as a ſlit, about two inches in length, downwards from the middle of that cut, taking care not to go deeper than the thickneſs of the bark, leſt the ſtock be wounded; then having the cutting in readineſs, the leaf ſhould be cut off from the bud, leaving the foot-ſtalk remaining, but taking off the bud lengthways ſomewhat longer than the ſlit in the ſtock, with part of the wood adhering to it; which being done, ſlip the wood from the bark with the knife by means of a ſudden jerk, obſerving whether the eye of the bud be left or not, as ſuch buds as loſe their eyes in ſtripping are quite uſeleſs: as ſoon as this has been done, the bark ſhould be gently raiſed on each ſide of the ſlit in the ſtock with the handle of the knife, and the bud inſerted into it, being careful to place it ſmooth between the rind and the woody part of the ſtock, cutting off that part of the rind of the bud which may happen to be too long for the ſlit: having thus exactly fitted the bud to the ſtock, they ſhould be tied cloſely round with wetted ſtrong baſs, taking care not to paſs any ligature round the eye of the bud, which muſt always be left open and at liberty. In the courſe of three weeks, or a month, the buds will require to be looſened of the bandage, and which, if not executed in time, will be highly injurious to them; but they ſhould not be wholly diveſted of the binding, it being proper to tie them again ſlightly, by which the bark of the ſtock will be prevented from becoming open, which ſometimes takes place, and the bud is thereby greatly injured, if not wholly deſtroyed.

There is nothing further required until the following March, when the ſtock ſhould be cut off about three inches above the place of inoculation, ſloping it the contrary way to the bud. This length of ſtock left is beneficial in faſtening the ſhoot which ſprings from the bud, and which might otherwiſe be blown out by ſtrong winds: in the autumn following, however, it ſhould be cut away quite cloſe juſt above the bud, that the wounded part may the more readily become barked over.

It may be noticed, that the moſt proper ſeaſon for this ſort of work is, from the middle of June until the middle of Auguſt, according to the forwardneſs of the ſeaſon, and the particular ſorts of trees to be increaſed; but it may be eaſily known by trying whether the buds will come off well from the wood or not. The moſt general rule is, when the buds are found to be formed at the extremity of the ſame year's ſhoots, which is a ſign of their having finiſhed their vernal growth. The firſt ſort commonly inoculated is the apricot, and the laſt that of the orange-tree, which ſhould never be done until the middle of Auguſt.

In doing this ſort of work, choice ſhould be made of cloudy weather, as when done in the middle of the day, in very hot weather, the ſhoots perſpire ſo faſt as to leave the buds deſtitute of moiſture; nor ſhould the cuttings be taken off from the trees long before they are uſed; but if fetched from ſome diſtance the leaves ſhould be cut off, but all the foot-ſtalks left, and then wrapped up in wet moſs, and put in a tin-box to exclude the action of the external air upon them. But the practice of throwing cuttings into water is highly improper, as it ſaturates the buds ſo with moiſture, that they have no attractive force left to imbibe the ſap of the ſtock, for want of which they very often miſcarry, and diſappoint the operator.

It has been remarked by Mr. Forſyth, that when the pear-trees which are grafted in the ſpring have not taken, he would adviſe the cutting them off a little below the graft at a joint or bud. The tree then throws out a great number of healthy ſhoots; all of which ſhould be rubbed off, except ſo many as are ſufficient to fill the wall; nailing thoſe up to prevent the wind from breaking them. About the latter end of July the ſhoots will be fit to inoculate, which ſhould then be done, leaving a little of the wood on the inſide of the bud when inſerted into the ſtock, and rubbing in ſome of the compoſition, tying on the baſs at the ſame time.

Having grafted ſome ſummer bonchrêtiens with the bergamot de Paſque (or Eaſter bergamot) and pear d'Auch in the ſpring, moſt of which failed, he cut them off below the grafts, and in July following they had produced ſhoots from five to ſix feet long, which he inoculated in the latter end of that month with the before-mentioned ſorts, which all took. About the beginning of September he ordered the baſſes to be ſlackened; which being left too looſe, the barks began to ſeparate. He then made them be tightened, letting them remain till the following ſpring. About the beginning of April, when he ſaw the buds begin to ſhoot, he cut the ſhoots near to the buds; but finding many where the bark had not united, and ſome of the eyes apparently dead, he took a ſharp penknife and cut out all the decayed bark, rubbing in ſome of the compoſition in a liquid ſtate, till the hollow parts were filled up; he then ſmoothed it off with the finger even with the bark of the ſtock. He alſo rubbed ſome of the compoſition over thoſe eyes that were in the worſt ſtate, being quite black, but with very little hope of recovery. " To his great aſtoniſhment, many of thoſe which ſeemed perfectly dead recovered, and by the middle of July had ſhoots from five to ſix feet long (many of the ſhoots which took well having fruit-buds formed for next year), and covered a ſpace of wall larger than a young tree would have done in eight years; all the cavities where he cut out the dead bark and applied the compoſition were, in the courſe of the ſummer, filled up with ſound wood, and the bark between the ſtocks and grafts perfectly united.

" Three years ago he inoculated ſome brown beurrés and craſanes with pear d'Auch, one of which now covers a wall ſixteen feet high and fifteen long, and has more fruit on it this year than a maiden tree would have produced twenty years after planting." But he " never recommends inoculating or grafting of old trees, except when bad ſorts, or more of any ſort is wanted for a ſupply; in that caſe he would recommend to inoculate or graft with pear d'Auch, colmars, and winter bonchrétiens, which keep much longer than beurrés, craſanes, &c."

But for ſtandards that have been grafted in the ſpring and have miſſed, he adviſes that they ſhould be cut below the graft, as, when ſo treated, they throw out a great number of ſhoots, which ſhould by no means be too ſoon thinned, as in that caſe they will be liable to be broken by the wind. The weakeſt ſhoots may be begun to be taken off about the latter end of May or beginning of June. About the middle of the latter month they will have acquired conſiderable ſtrength, then thin them, leaving as many ſtrong regular ſhoots, and of thoſe neareſt the top of the ſtem, as will form a handſome head. If the ſtem be very ſtrong, it will be neceſſary, perhaps, to leave more than are intended to be inoculated on purpoſe to receive the ſap, which will flow in great abundance from a large trunk, and without this precaution be apt to burſt the ſhoots. He has often ſeen ſhoots as large as his arm burſt by a ſuperabundance of ſap. When that is likely to happen, the beſt thing is to ſcarify the ſhoots and rub a little of the compoſition into the wound. See Bud, Budding, and Grafting.

INOCULATION, among *Gardeners*, ſignifies an operation in the management of ſome ſorts of fruit-trees, which is frequently denominated *budding*. See Budding, and the preceding article.

Inoculation, in a *ſurgical* and *medical* ſenſe, denotes the practice of deſignedly communicating from one perſon to another certain diſeaſes, which is generally done by introducing ſome of the infectious matter into a ſmall wound, or puncture, made with the point of a lancet. The common purpoſe of ſuch operation is to diminiſh the ſeverity and peril of a diſtemper, which, taken in a caſual way, proves exceedingly deſtructive, and the hazard of catching which, at ſome period of life or another, is very conſiderable. A chief object of the plan is alſo, in general, to render the patient incapable of being again affected by the dreaded contagion. Hence inoculation is ſeldom performed, but for a diſeaſe with which the human conſtitution can only be affected once, as the ſmall-pox and cow-pox. The latter, which is ſo mild as ſcarcely to deſerve the name of a diſeaſe, being only communicable by contact, and exiſting originally no where except upon the teats and udders of cows, would never perhaps have troubled any other perſons than a few milkers, had it not been for the diſcovery of the important fact, that perſons who had undergone the complaint were made completely unſuſceptible of the ſmall-pox contagion. The cow-pox inoculation has now, therefore, been very generally ſubſtituted for that with variolous matter, and the beneficial conſequences of this change are ſo truly important that the Jennerian diſcovery will ever be regarded as a moſt memorable event, not only in the annals of medicine and ſurgery, but in the hiſtory of the world. See Cow-Pox and Vaccination.

Although it is our intention to devote this article to the hiſtory of the ſmall-pox inoculation, we may here remark, that the meaſles have been propagated by inoculation. Dr. Home, of Edinburgh, was the firſt who actually made the experiment. Not being able to collect either matter, or a ſufficient quantity of broken cuticle at the time of deſquamation, to produce the diſeaſe, he drew blood from a ſuperficial cutaneous vein, where the eruption was thickeſt. Cotton was then dipped in this blood, and applied to a wound made in each arm of the perſon about to be inoculated. In this manner Dr. Home inoculated twelve perſons. The eruptive fever generally began ſix days after inoculation; the ſymptoms were leſs ſevere; the cough was milder, or entirely abſent; and the inflammation of the eyes was trifling. Notwithſtanding Dr. Home's ſucceſs, inoculation for the meaſles is ſeldom or never practiſed, others, who have made the experiment, not having given reports equally favourable.

Inoculation for the plague has likewiſe been tried, in order to aſcertain whether that diſtemper might not be rendered leſs fatal and leſs prevalent in particular parts of the world. In Egypt, Dr. Whyte inoculated himſelf with matter taken from the buboes of an infected perſon. The attempt failed twice; and the third proval fatal in three days after the commencement of the ſymptoms. See ſir R. Wilſon's Hiſt. of the Expedition to Egypt.

In the preſent ſtate of our information, inoculation for the plague appears unjuſtifiable. It was aſcertained in Egypt, that many of the convaleſcents took the plague a ſecond time; nor, in all probability, does inoculation render this diſtemper milder. Indeed, what M. Sonnini obſerves, ſeems to lead to a contrary concluſion; for he mentions, that a Ruſſian ſurgeon, who was a priſoner at Conſtantinople, with a number of his countrymen, took it into his head to inoculate theſe unfortunate men with the plague, under the idea of rendering the contagion leſs deſtructive; but the reſult was, that two hundred loſt their lives, as well as the ſurgeon, who had alſo inoculated himſelf. See Sonnini's Travels into Greece and Turkey, p. 497.

The idea of intentionally imparting any kind of diſeaſe to the human body would appear, to perſons unacquainted with the reaſon of the thing, equally extraordinary and cruel. But the deſign and utility of the inoculation for the ſmall-pox are now ſo fully known among all claſſes of ſociety, as ſcarcely to need explanation. When it is remembered, that the ſmall-pox contagion has, at various periods, nearly depopulated extenſive kingdoms, and occaſioned greater devaſtation than the moſt deſtructive wars, any meaſure, calculated to render milder ſo terrible a diſeaſe, muſt be looked upon as a diſcovery of the very higheſt importance. It has been eſtimated, that, upon an average, before the introduction of inoculation, one out of every ſix perſons affected with the natural ſmall-pox, or ſometimes even a half, periſhed; but that the proportion of deaths, among ſuch as have been inoculated in the moſt improved manner, does not amount to more than one in ſeveral hundreds. Beſides this circumſtance, we have to mention, that before inoculation became common, the ſmall-pox frequently committed ravages like the plague, and the fury of the diſtemper was always dreadful whenever the contagion made its firſt viſit to a country. If, then, we are to hail the ſmall-pox inoculation as a general and momentous benefit to ſociety, on the principles juſt now ſpecified, with what joy and admiration muſt we behold the diſcovery of a complete ſecurity againſt the ſmall-pox infection, in the new and perfectly ſafe kind of inoculation with vaccine lymph. The ſmall-pox inoculation materially alleviated the calamities ariſing from that contagion, by making the diſeaſe milder, and leſſening its mortality. But, ſtill, the diſtemper was not unfrequently ſeen in a ſevere form; at leaſt one out of every three or four hundred inoculated died; and the countenances of thoſe who ſurvived were often miſerably pitted and diſfigured. On the other hand, the vaccine inoculation hardly ever produces any ſerious indiſpoſition, and being followed by no eruption, cannot deform the face. Its ſafety and efficacy are daily receiving more and more confirmation from all quarters of the world, and we have no doubt that, after prejudices have had time to ſubſide, the ſmall-pox inoculation will be univerſally ſuperſeded.

The original introduction of inoculation, however, will always conſtitute a moſt memorable event in hiſtory, and is a ſubject too intereſting to be omitted in our work. After a few obſervations on the commencement of the ſmall-pox, we ſhall therefore endeavour to give ſome account of the riſe and progreſs of the practice.

Origin of the Small-pox.—The ſmall-pox, like the meaſles, and ſeveral other diſeaſes, is produced by a matter *ſui generis*, or, in other words, by a ſpecific contagion, and it has originated from cauſes ſo perfectly incomprehenſible, as to ſet at defiance all rational conjecture. From the ſilence of the ancient Greeks and Romans reſpecting a diſeaſe ſo very fatal, and of ſuch peculiarity, as the ſmall-pox, it is reaſonable to conclude, that its date is ſubſequent to their times, and, conſequently, that the world exiſted ſeveral thouſand years before it was viſited by this dreadful peſtilence. Rhazes, an Arabian phyſician, who practiſed at Bagdad in the beginning of the tenth century, is one of the oldeſt writers on the ſmall-pox, whoſe works are ſtill extant. On this ſubject, however, he quotes ſeveral of his predeceſſors, the moſt ancient of whom is Ahron, who was a prieſt and phyſician at Alexandria, when that city was beſieged by the Saracens. Ahron's book has, therefore, been deemed the firſt in which any notice is taken of the ſmall-pox. The introduction of the diſeaſe, at that time, into Egypt, might have been by the armies of Amrou, which, in the kaliphate of Omar, poured in thither from Arabia.

The celebrated Dr. Friend conceived, that the Arabians might originally have derived the contagion from ſome of the more diſtant regions of the Eaſt, and Père D'Entrecolles, a miſſionary jeſuit at Pekin, informs us, that, upon looking over ſome Chineſe books, he found the ſmall-pox mentioned in them as a diſeaſe known in very ancient times. See "Lettres edifiantes et curieuſes," tom. 21. p. 33. ed. 1781.

Mr. Holwell, a Bengal ſurgeon, has likewiſe endeavoured to confirm the accuracy of Dr. Friend's opinion, obſerving, that, "at the period in which the Aughtorrah Bhade ſcriptures of the Gentoos were promulged, (according to the Bramins 3366 years ago,) this diſeaſe muſt then have been of ſome ſtanding, as thoſe ſcriptures inſtitute a form of divine worſhip, with poojahs, or offerings, to a female divinity, ſtyled by the common people Goote ka Tagooran, the Goddeſs of Spots, whoſe aid and patronage are invoked during the continuance of the ſmall-pox ſeaſon; alſo in the meaſles, and every cutaneous eruption that is in the ſmalleſt degree epidemical. See "An Account of the Manner of inoculating the Small-pox in the Eaſt Indies," p. 7.

On the other hand, Dr. Woodville is unwilling to admit, that the ſuppoſed antiquity of the ſmall-pox in India is at all proved by what D'Entrecolles and Mr. Holwell have obſerved. He remarks, that the former has adduced no direct fact, ſhewing, that the diſeaſe was really deſcribed by the ancient Chineſe phyſicians; while Mr. Holwell's reaſons muſt be inconcluſive, not only as founded on the verity of the Hindoo chronology; but becauſe the Goddeſs of Spots was not ſuppoſed to preſide over any particular eruptive diſorder, but over all cutaneous affections that were epidemical. Beſides, as Dr. Woodville juſtly notices, had the ſmall-pox exiſted in India more than 3366 years, it could not fail to have been tranſported in early times both to the Greeks and Romans, by the conſtant intercourſe, which they indirectly maintained with the Indian nations.

Dr. John James Reiſke mentions, that, in an old Arabic MS. preſerved in the public library at Leyden, he read, that, in the year of the birth of Mahomet, the meaſles and ſmall-pox made their firſt appearance in Arabia. Diſp. inaug. Lugd. Bat. 1746. Now it appears alſo from ſome Arabian annals, procured by that adventurous traveller, Mr. Bruce, that the era of the firſt appearance of the ſmall-pox in Arabia attaches to that of the ſiege of Mecca, and that the Abyſſinian army, commanded by Abrahah, was the firſt victim of its fury. Mr. Gibbon ſtates, that the ſiege of Mecca happened only two months before the birth of Mahomet; a fact, which Dr. Woodville points out as deſerving very particular notice; for if the year of the birth of Mahomet be aſcertained to be alſo that of the ſiege of Mecca, the Arabian MS. cited by Dr. Reiſke, and that written by Hameeſy, the Arabian author mentioned by Mr. Bruce, perfectly coincide. According to Gibbon, Mahomet was born A.D. 569; which, on the above independent authorities, is to be conſidered as the period when the ſmall-pox firſt made its appearance in Arabia.

From this era, to that of the conqueſt of Alexandria in 640, no traces of the exiſtence of the ſmall-pox are to be diſcovered; but the diſeaſe certainly ſpread into that city at the time it was inveſted by the Saracens; and, as Dr. Woodville ſtates, it may therefore be ſuppoſed to have been brought into Egypt by the Mahometan army, which, ſix years before, had invaded Perſia and Syria, where this deſtructive peſtilence probably had already made a conſiderable progreſs.

After this period, to the revival of literature in the 15th century, ſucceeded that general ſtate of ignorance and barbariſm, during which the preſent ſubject, in common with many others, is ſo obſcured in the darkneſs of the times as to elude the moſt diligent reſearch.

It is manifeſt from the works of Rhazes, that many of the Arabian phyſicians had written on the ſmall-pox before the 10th century; and notwithſtanding the Saracen hiſtory is ſilent on the ravages which muſt have accompanied the general diffuſion of the ſmall-pox during the empire of the caliphs, the progreſs and prevalence of the diſtemper are to be inferred from collateral evidence. Thus, the caliph Yezid, who died in 683, is mentioned as being pitted with the ſmall-pox; and the caliph Abul-Abbas Alſaffah actually died, in 753, of this diſeaſe.

The time when the ſmall-pox contagion firſt ſpread into Great Britain is involved in doubt. Moſt writers ſuppoſe that the diſtemper was imported into Europe by the cruſaders, upon their return from the Holy Land in the 13th century. The improbability of this ſtatement is inſiſted upon by Dr. Woodville, who adverts to the known activity of variolous matter, the long time it retains its infectious quality, and the unlikely circumſtance of the ſmall-pox prevailing ſix or ſeven centuries over various parts of Aſia, having free intercourſe with Europe, before it was conveyed into this kingdom. It is indeed ſurpriſing, that the dreadful effects which muſt have attended the firſt introduction of the ſmall-pox into this as well as any other country, have eſcaped the notice of all our hiſtorians and medical writers. But, by examining ſome of the MSS. of the Harleian and Cottonian collections, preſerved in the Britiſh Muſeum, and bearing indubitable evidence of having been written before the year 900, Dr. Woodville ſucceeded in tracing the exiſtence of the ſmall-pox in our iſland, and on the neighbouring continent, long before the cruſades took place. In theſe curious records the word *variolæ* occurs ſeveral times in the ſame ſenſe in which it is now uſed. We likewiſe learn from the MSS. that the people in thoſe early times lived in continual dread of the ſmall-pox, as ſeveral prayers, exorciſms, and incantations, to which they had recourſe for preſervation, are to be found. Dr. Woodville refers us to No. 585, of the Harleian Catal. vol. i. and Bibl. Cotton. Caligula A. 15. No. 30.

The firſt Britiſh medical writers of any note were thoſe of the 13th century, and they, as well as all their ſucceſſors, from John of Gaddeſden to the immortal Sydenham, &c. have beſtowed much attention on this important diſtemper.

Hiſtory of Inoculation of the Small-pox.—The exact part of the world where inoculation was firſt adopted is quite unknown ; nor do we poſſeſs any information of the circumſtances which originally ſuggeſted the benefit that might reſult from the practice. From the Arabian phyſicians having been the firſt informed of the nature and treatment of the ſmall-pox, it has been ſuppoſed that inoculation had its origin among them. (See Second Memoire ſur l'Inoculation par M. de la Condamine.) Avicenna, who lived at Bokhara on the eaſt coaſt of the Caſpian ſea, or his diſciples, have in particular been ſuſpected of being the authors of this valuable invention, in conſequence of the countries between the Caſpian and Euxine ſeas being the ſuppoſed centre from which inoculation ſpread to other places. Dr. Woodville, however, conſiders this conjecture as very ill-founded. He contends that we have no evidence that any of the people near the Caſpian ſea were the firſt practiſers of inoculation. Had the invention originated in this part of the world, the Tartars could hardly have been ſo ignorant of the practice, as, according to D'Entrecolles, they actually were in the year 1724. Nor is it probable that the method ſpread from weſt to eaſt ; for as the ſame author has obſerved, inoculation is more ancient in the eaſtern parts of China than it is in the weſtern provinces of that empire. Dr. Woodville remarks that inoculation was certainly firſt introduced into Conſtantinople from the Morea ; but as the event did not take place till towards the end of the 17th century, we may conclude, that, had the art been practiſed for many ages, at ſo ſhort a diſtance from that metropolis, it would have been known there much ſooner. Beſides, in various countries, very remote from the Caſpian ſea, it is proved to have been an immemorial uſage.

Inoculation was introduced into London as a foreign invention, and, from its ſucceſs upon the younger branches of the royal family in 1722, became the ſubject of public converſation, when, to the great ſurpriſe of the learned, ſeveral communications proved that it was already a practice known in South Wales, where it had exiſted under the denomination of buying the ſmall-pox as far back as tradition could be traced. The manner of inoculating, or buying the ſmall-pox, here alluded to, was ſubject to variety. Some perſons either rubbed the matter, taken from the puſtules, when ripe, on ſeveral parts of the ſkin of the arms, &c. or pricked ſuch parts with pins, or other pointed things, firſt infected with the ſame matter. Some ſcraped the ſkin with a knife, until the blood began to flow, before they applied the variolous pus. Others produced the diſtemper by holding a certain number of dried puſtules, for a conſiderable time, in the palm of the hand. (See the Letters of Dr. Williams, Mr. Owen, and Mr. Wright, in the Philoſophical Tranſactions for 1722, and Dr Jurin's account of the ſucceſs of inoculation in 1723.) The inhabitants of the Highlands of Scotland have alſo for many ages performed a kind of inoculation by tying worſted threads, moiſtened with variolous matter, round the wriſts of their children. (Monro on Inoculation in Scotland.) The ſame cuſtom likewiſe prevailed in many other parts of Europe, Aſia, and Africa ; and, what is highly curious, the practice was, in ſeveral of theſe diſtant countries, termed *buying the ſmall-pox*, juſt as it was in South Wales ; for it was ſuperſtitiouſly imagined that inoculation would not produce the proper effect, unleſs the perſon from whom the variolous matter was taken received a piece of money, or ſome other preſent, in exchange. The practice of buying the ſmall-pox has been found to have prevailed from time immemorial, not only in South Wales, but alſo at Naples, Pavia, in Auvergne and Perigord, and among the peaſantry in many parts of Germany, Denmark, and Sweden. See Second Mem. ſur l'Inoculation, par M. de la Condamine ; Murray's Hiſtoria Inſitionis Variolarum in Suecia ; Schultz's Account of Inoculation, &c.

In Barbary and the Levant the variolous matter was alſo purchaſed, and inſerted in a ſmall inciſion made in the fleſhy part of the hand between the thumb and the fore-finger. (See Shaw's Travels into Barbary and the Levant.) In Tripoli, Tunis, and Algiers, an inciſion was made on the back of the hand, between the thumb and fore-finger, and a little of the variolous matter put into the wound. According to Dr. P. Ruſſel, inoculation is ſo ancient in theſe laſt kingdoms that nobody remembers its firſt riſe ; and it has been practiſed not only by the inhabitants of the towns, but alſo by the wild Arabs. (See Phil. Tranſ. vol. lvi. p. 140.) It appears, moreover, from this gentleman's account, that buying the variolous matter and inoculating have been ancient cuſtoms at Bagdad, Moſul, and Baſſora, in Armenia, at Damaſcus, and all along the coaſt of Syria and Paleſtine. The Arabs aſſured Dr. Ruſſel that the puncture might be made indifferently in any fleſhy part ; but he moſtly found the mark between the thumb and fore-finger. Some of the Georgians had been inoculated in the ſame part, though moſt of them in the fore-arm. Some of the Armenians had been inoculated in both thighs ; but the greater part, like the Arabs, bore the mark upon the hand.

D'Entrecolles, by obtaining acceſs to ſeveral medical books at Pekin, diſcovered one in which an account was given of the introduction of inoculation into China. The author of the book here alluded to, lived in the latter part of the dynaſty of Ming. Hence it has been concluded that inoculation has not yet been practiſed in China 200 years. But in Hindooſtan the cuſtom can be traced much farther back. The methods of practiſing this art by the Chineſe and Hindoos are alſo ſo widely different, that they cannot have been derived from the ſame origin. The Chineſe take from two to four dried variolous puſtules, or ſcales (according to their ſize), between which they place a ſmall portion of muſk ; the whole is then wrapped up in cotton, and introduced into the patient's noſtril. The ſcales before uſed are kept in a cloſe jar for ſeveral years, and when the Chineſe are obliged to employ recent puſtules, they think it neceſſary to correct the acrimony of the matter, by expoſing it to the ſteam of an infuſion of the roots of ſcorzonera and liquorice. They ſometimes reduce the dried ſcales into powder, and form them into a paſte for the purpoſe of inoculation.

Dr. Woodville very properly obſerves, that the application of variolous matter, wrapped in cotton, within the noſtrils, muſt be an exceedingly precarious mode of communicating the ſmall-pox, and may perhaps afford a reaſon why inoculation in China is leſs ſucceſsful than in other countries ; for if the matter acts in the way of inoculation, a troubleſome inflammation of the Schneiderian membrane muſt enſue ; and, ſhould not this take place, the variolous effluvia, by being inhaled into the lungs, will produce the natural ſmall-pox.

In Hindooſtan inoculation is performed by a particular tribe of Bramins. They do not refuſe to inoculate on any part ; but, in males, they prefer the outſide of the arm, midway between the wriſt and the elbow, and, in females, the ſhoulder. The operator firſt rubs the part with a dry cloth for eight or ten minutes, and then ſlightly pricks it at many points. He next takes a ſmall pledget of cotton, charged with the variolous matter, moiſtens it with two or three drops of the Ganges water, applies it to the punctured part, fixes it there with a bandage, and orders it to be kept on for ſix hours. The bandage is then to be taken off, the pledget being left to fall off of itſelf. The matter in the cotton is always taken from puſtules of the preceding year, freſh matter, and ſuch as is the product of the natural ſmall-pox, being conſidered improper. See Holwell's Account of the Manner of inoculating in the Eaſt Indies.

It was immediately from Conſtantinople that the Engliſh firſt derived a full knowledge of the advantages of inoculation. The beneficial conſequences of the practice among the Turks, were detailed by Dr. Emanuel Timoni, communicated by Dr. Woodward to the Royal Society, and publiſhed in the Tranſactions of that body for the year 1714. The Byzantine mode was to take ſome freſh variolous matter in a glaſs veſſel, and drop it on punctures or ſcratches made with a needle or lancet in any fleſhy part, but eſpecially in the arm and fore-arm. The matter, which was dropped on the punctured place, was well blended with the drops of blood iſſuing from the wounds, by means of a blunt ſtile or ear-picker. The part was then kept covered with a walnut ſhell for a few hours, in order to prevent the matter from being rubbed away.

Another account of the Byzantine mode of inoculation was afterwards publiſhed by Dr. Pylarini in the ſame volume of the Tranſactions of the Royal Society for 1716. But the year before this gentleman's obſervations appeared, ſurgeon Kennedy had printed an account of the new method of inoculating at Conſtantinople, in his "Eſſay on External Remedies," and he ſeems to be the firſt Britiſh author on the ſubject of inoculation. Soon afterwards, lady Mary Wortley Montague, the wife of the Engliſh Ambaſſador at Conſtantinople, in her letters, confirmed the accounts of the remarkable manner in which the ſeverity and mortality of the ſmall-pox were diminiſhed among the Turks by means of inoculation; and, in one of her epiſtles from Adrianople, ſhe expreſſed her intention to try the experiment upon her own little ſon. See vol. ii. let. 31.

The mode of performing the operation at Conſtantinople gradually became more and more ſimple. We learn from Pylarini, that, in 1701, inciſions were made in the forehead, cheeks, chin, and alſo in the extremities, for the purpoſe of inoculation. Timoni likewiſe, twelve years afterwards, mentions, that the operator is to make ſeveral little wounds in one or more places of the ſkin, and theſe ſucceed beſt in the fleſhy parts of the arm. In the year 1717, the inſertion of variolous matter, at a ſimple puncture in each arm, ſeems to have been the prevailing method of inoculation, as will appear by the following relation: Mr. Maitland, ſurgeon to the honourable Wortley Montague in his diplomatic character at the Ottoman court, informs us, that the ambaſſador's lady, being convinced of the advantages of inoculation, determined that her only ſon, then ſix years of age, ſhould undergo the operation. For this purpoſe, ſhe deſired Mr. Maitland to procure the variolous matter from a proper ſubject, which being done, an old Greek woman, many years in the conſtant habit of inoculating, was employed to inſert it. "But (ſays Mr. Maitland) the good woman went to work ſo awkwardly, and, by the ſhaking of her hand, put the child to ſo much torture with her blunt and ruſty needle, that I pitied his cries, and therefore inoculated the *other arm* with my own inſtrument, and with ſo little pain to him, that he did not in the leaſt complain of it." (Maitland's Account of Inoculating the Small-pox, p. 7.) The conſequent diſeaſe was very mild, and, if the mode of buying the ſmall-pox be excepted, this inoculation, which was done at Pera, near Conſtantinople, in March 1717, was the firſt ever practiſed upon any Engliſh ſubject.

The inoculation of the ſmall-pox was firſt regularly adopted in England in the month of April 1721. The practice, in all probability, would not have been ſo ſoon purſued by the faculty, had it not been for the enlightened and philoſophic mind of lady Mary Wortley Montague. After this celebrated lady had witneſſed the good effects of inoculation upon her ſon at Pera, ſhe determined alſo to try it upon her daughter, then an infant three months old; but for certain domeſtic reaſons, the operation was at that time deferred, ſo that this child was fortunately reſerved to be the firſt example of inoculation in England, which was done by Mr. Maitland, in April 1721. According to Dr. Woodville, writers have univerſally erred, in dating this event in April 1722, and making it ſubſequent to the inoculation of the malefactors at Newgate. He notices that Mr. Maitland's pamphlet, in which all the circumſtances are ſtated, was publiſhed in February 1722, as appears by the advertiſement prefixed to the work. Therefore Mr. Maitland, in ſaying April *laſt*, could mean no other than that in the year 1721. Beſides, Mr. Maitland expreſsly mentions, that this was the firſt example of inoculation in England.

After the ſucceſsful reſult of this caſe, Mr. Maitland performed the ſecond inoculation ever done in this country, in the month of May 1721, upon the ſon of Dr. Keith, and with the beſt effects. Notwithſtanding theſe confirmations at home of the favourable accounts of the practice which had been already received from Conſtantinople, and notwithſtanding the firm and powerful patronage which the Byzantine inoculation met with in lady Mary Wortley Montague, it is a fact, that ſuch was the ſuſpicious caution with which the method was received, that ſeveral months elapſed before a third trial of it was made in London. Indeed, the very next experiment that was undertaken ſtrikingly evinces the dangerous light in which inoculation was ſtill regarded; for it was determined that ſeveral culprits in Newgate, who had forfeited their lives to the laws of their country, ſhould, on ſubmitting to be inoculated, receive full pardon by the royal prerogative. Six condemned criminals were inoculated by Mr Maitland, on the ninth day of Auguſt 1721, in the preſence of ſeveral eminent phyſicians and ſurgeons. Theſe malefactors all obtained a remiſſion of their ſentence on very eaſy terms. None of them had the diſeaſe ſeverely, and one, who had already had the ſmall-pox, was of courſe not affected a ſecond time. A ſeventh criminal, a young woman, was next pardoned, on condition of having the Chineſe method of inoculating tried upon her, at the wiſh of Dr. Mead. Conſequently, ſome cotton, moiſtened with variolous matter, was introduced in her noſtrils; the diſtemper followed in a mild form: but the patient ſuffered violent pains in her head, from the commencement of the eruption to the maturation of the puſtules.

After theſe public proofs of the ſafety and advantage of inoculation, objections and doubts were ſtill adduced againſt the method. Some conſidered the caſes too few, while others, in conſequence of the ſmall number and mildneſs of the puſtules, thought it doubtful whether the genuine ſmall-pox had been at all communicated. Hence, in the courſe of the following ſix months, Mr. Maitland inoculated only eight ſubjects, who all recovered, though two, it muſt be confeſſed, had the ſmall-pox ſo ſeverely, as to be for ſome time in danger. See Maitland's Account of Inoculating the Small-pox, 1722.

Maitland's publication was immediately afterwards followed by a letter from Dr. Nettleton, who, in December

1721, and the two ſubſequent months, had inoculated with ſucceſs upwards of forty perſons at Halifax, in Yorkſhire. This relation influenced the public very conſiderably in favour of the new mode of communicating the ſmall-pox.

Early in the ſpring of the year 1722, inoculation began to be adopted in various parts of England; and by order of her royal highneſs the princeſs of Wales, it was practiſed firſt upon ſix, and afterwards upon five charity children, belonging to the pariſh of St. James's. The ſucceſs of theſe trials induced her royal highneſs to have the princeſſes Amelia and Carolina inoculated on the nineteenth of April 1722, by ſerjeant ſurgeon Amyand. Both theſe younger branches of the royal family paſſed through the ſmall-pox, in a very favourable manner; and inoculation, in conſequence of this illuſtrious example, was now making a rapid progreſs: when unfortunately the practice received a great check, by the death of the earl of Sunderland's ſon, and by that of lord Bathurſt's ſervant, after being inoculated. A Miſs Rigby alſo died, about eight weeks after her inoculation, making the third death. Therefore, out of 182 inoculations, in 1721 and 1722, three died; or nearly one in ſixty.

About the time when the firſt death happened in London, accounts were received in town, ſtating that the practice had been tried to a much greater extent in New England. It appears that, after an abſence of nineteen years, the ſmall-pox had broken out with a great mortality at Boſton, in April 1721. This induced the Rev. Mr. Mather to publiſh the account of inoculation, as related in the Philoſophical Tranſactions by Timoni and Pylarini. This publication, which was diſtributed to all the medical practitioners at that place, was the means of inciting Dr. Boylſton to commence the practice of inoculation upon his own child, and two negro ſervants, at the latter end of June 1721. In the courſe of ſix months, he inoculated in and about Boſton 244 perſons. Of this number ſix died.

The reports which came from New England, were employed with great exaggeration by the opponents of inoculation, who ſeized with avidity every circumſtance that might have the leaſt tendency to retard the progreſs of the improvement.

During 1723, the practice of inoculation became much more general in England, the number of inoculated this year far exceeding the numbers in the two preceding years taken together. It amounted to 292, which, added to 182, makes the whole number of inoculations in the years 1721, 1722, and 1723, to be 474, of which number, according to Dr. Jurin, nine died.

It deſerves notice, that ſeveral of theſe nine caſes were not generally admitted as deaths altogether in conſequence of inoculation. But even allowing that they were ſo, the chance of recovering from the inoculated ſmall-pox muſt appear infinitely greater than from the caſual. For it was proved, that at this time, out of 14,559 perſons who had been affected with the natural ſmall-pox, 2351 died; nearly one in ſix, or five out of thirty-one.

In 1724, there were only forty perſons inoculated. Their royal highneſſes prince Frederick and prince William, however, were in this ſmall liſt. Dr. Jurin accounts for the ſeeming decline of inoculation this year, by the fact that people will not eaſily ſubmit to a practice in which they apprehend riſk, unleſs impelled by the dread of a greater danger. Now it appears that in 1724, the natural ſmall-pox was much leſs fatal than in 1722 and 1723, and it is to this cauſe we are to refer the above ſmall number of inoculations. That the practice had not fallen into diſrepute is manifeſt; for Dr. Jurin informs us that in 1725 the natural ſmall-pox was very mortal, and of courſe, people being frightened, reſorted to inoculation again in a larger number. Of the above-mentioned forty, one is recorded to have died.

In 1725 and 1726, 256 perſons were inoculated, of which number four died.

In the years 1727 and 1728, the practice of inoculation did in reality begin to decline; for, though the ſmall-pox was very prevalent and fatal, only 124 inoculations took place in theſe two years, and three of the caſes proved fatal.

We find that up to 1729, 897 perſons had been inoculated in England, of whom ſeventeen are reported to have died. But on the other hand, the records ſhew, that of 18,229 perſons, who had been affected with the natural ſmall-pox, during the firſt eight years of inoculation, 3008 died under the diſeaſe; or about one in ſix; whereas, the deaths by inoculation, admitting the utmoſt number contended for, does not exceed one in fifty. The reaſon why more died of inoculation at this early period of the practice than has been the caſe of late years, is juſtly aſcribable to the better manner lately adopted of treating inoculated patients. Beſides, formerly it was common to inoculate adults, in whom the diſeaſe is more diſpoſed to aſſume a ſevere form than in children.

Inoculation was not regularly practiſed in Scotland till the year 1726, when Mr. Maitland performed this operation upon ten perſons; but as one of theſe caſes was unſucceſsful, the practice was diſcontinued in that country for twenty years afterwards, and was not revived again without conſiderable difficulty. At Dumfries, indeed, where the caſual ſmall-pox had committed great ravages, inoculation was had recourſe to in 1733; but in moſt other parts of North Britain the method was not introduced till 1753.

In Ireland, inoculation was firſt performed at Dublin in 1723. Twenty-five perſons were inoculated in that and the three following years. Of this ſmall number, three caſes terminated fatally.

Inoculation at Hanover was firſt performed in 1724, by Mr. Maitland, upon his royal highneſs prince Frederick, and afterwards upon eight children of the Baron de Schulenberg. The example and ſucceſs of theſe caſes had the effect of eſtabliſhing the practice in that country.

After 1729, inoculation was ſeriouſly on the decline in England; but it made conſiderable progreſs in the tranſatlantic world. In South Carolina, about the year 1738, not leſs than 800, or 1000 perſons were inoculated, of whom only eight died. The account of this ſucceſs contributed materially to revive the practice in Great Britain. In Philadelphia, likewiſe, inoculation proved ſoon afterwards ſtill more favourable; and in St. Chriſtopher's 300 ſlaves were inoculated, without the loſs of one.

Such facts in favour of the practice, and the great fatality of the natural ſmall-pox in Britain, ſoon led people to adopt inoculation more extenſively than ever, and from the year 1738, this beneficial method may be regarded as having been completely and generally eſtabliſhed, though partial oppoſition prevailed long afterwards.

In the year 1746, the inſtitution called the Inoculation Hoſpital had its riſe, though it was not at firſt ſo conſiderable an eſtabliſhment as at preſent. Here the ſucceſs of inoculation did not diſappoint the hopes and zeal of its patrons; for out of 593 caſes of perſons ſucceſſively inoculated, from the year 1751, only one proved unſucceſsful.

In 1754, it was determined to inoculate the three royal children, who had not yet had the ſmall-pox. In the mean time, his preſent majeſty took the diſeaſe caſually, ſo that only the prince Edward, and the princeſs Auguſta, were inoculated. Theſe great examples, and the public approbation of the practice declared by the College of Phyſicians, gained numerous advocates to the cauſe, which never afterwards loſt ground, till the ſtill ſafer and milder mode of inoculation with vaccine lymph was brought into notice by the immortal Jenner.

In France, Dr. Boyer is the firſt writer who has noticed inoculation, which he did in 1717. In 1723, the ſucceſsful trials of inoculation in England were publiſhed at Paris by Dr. de la Coſte, and the conſequence was a declaration by the phyſicians of that city, "that for the benefit of the public, it was lawful to make trials of inoculation." The practice was on the point of having a beginning in the hoſpitals, under the ſanction of the duke of Orleans, the regent, when, unfortunately for the experiment, this nobleman died, and ſoon afterwards Dr. Hecquet publiſhed his "Raiſons de doute contre l'Inoculation." The ſentiments contained in this publication, and in a theſis written at Paris in 1723, the reports of the ill ſucceſs of inoculation at Boſton, and the great mortality of the natural ſmall-pox in London, in 1723, falſely aſcribed to the new practice, ſoon brought the method into diſrepute in France, and the deſign of trying it there was laid aſide.

The French paid little attention to the ſubject again till 1752, when Dr. Buttini, of Montpelier, publiſhed at Paris his "Traité de la Petite Verole communiquée par l'Inoculation." Two years afterwards, M. de la Condamine read his excellent memoir upon the advantages of inoculation, before a public aſſembly of the Royal Academy of Sciences at Paris. But, according to Dr. Woodville, the practice was not introduced into France till the 1ſt of April 1755, when, at the deſire of M. Turgot, a child, four years old, was inoculated at Paris. On the 14th of May, M. Chaſtellux, aged 21, voluntarily ſubmitted to the operation. About this time, Dr. Hoſty, who had been attending the ſmall-pox and inoculation hoſpitals in London, at the requeſt of the French miniſter, publiſhed at Paris the following report :—"That out of 463 caſes of perſons laſt inoculated in the hoſpital, only one had been unſucceſsful; whereas, in the Small-pox hoſpital, it appeared by the regiſters, that nearly one in four had died of the natural ſmall-pox."—"That Mr. Ranby, principal ſurgeon to his majeſty, had inoculated 1600 perſons; and that Mr. Bell, pupil to Mr. Morand, had inoculated 903, without the loſs of one."—"That in order to form a juſt comparative view of the fatality of inoculation and of the natural ſmall-pox, it is only requiſite to viſit the two hoſpitals in London, the difference of their reports being ſo remarkable, that it muſt convince the moſt incredulous of the advantages of inoculation." Laſtly, "with reſpect to the inoculation of other diſeaſes along with the ſmall-pox, that no inſtance of the kind has ever been produced; and that perſons have been inoculated with variolous matter, taken from a patient affected with the venereal diſtemper, yet have thereby received the infection of the ſmall-pox only."

This ſtatement had immenſe effect in promoting the introduction of inoculation into France; and in the year 1756, the family of the duke of Orleans, and great numbers of the firſt rank, were inoculated by Drs. Tronchin, Hoſty, and others. In 1758, the practice had diffuſed itſelf over various parts of France. The inoculated were not, however, very numerous, and one or two unſucceſsful caſes, joined with falſe reports, that ſome perſons had taken the natural ſmall-pox after undergoing inoculation, once more caſt diſcredit upon the plan, and excited a violent controverſy. The great fatality of the ſmall-pox at Paris in 1763, being imputed to inoculation, the practice was forbidden by parliament. At length the faculty of phyſic, and that of theology, were called upon to decide, whether inoculation ought to be tolerated or proſcribed. This meaſure ſerved to increaſe the diſputes; nor was it till a very late period that inoculation was extenſively practiſed in France.

In Holland, inoculation was begun at Amſterdam in 1748 by Dr. Tronchin, who, on finding one of his ſons ſeized with the natural ſmall-pox, immediately inoculated the other. This phyſician, after his return from Geneva, in 1754, inoculated a great many perſons in Holland. Dr. Schwenke, at the Hague, likewiſe promoted the practice; and ſo did a ſociety of phyſicians and ſurgeons at Rotterdam, who were aſſociated for the purpoſe in 1757. The method was not, however, very generally adopted by the Dutch, till after 1764, about which time Morand and others had practiſed it at Amſterdam with ſtriking ſucceſs.

Inoculation was firſt introduced into Denmark in September 1754, when the counteſs of Bernſdorff underwent the proceſs. In 1758, two inoculation houſes were eſtabliſhed at Copenhagen; and, in 1760, the prince royal was inoculated with ſucceſs.

In Sweden, the firſt trial of inoculation was made by Haartman in 1754. The rapid progreſs of the method in Sweden was owing to the encouragement afforded by the Swediſh court. Dr. D. Schultz was deputed to enquire into the ſucceſs of the plan at the inoculation hoſpital in London, and the accounts which he gave upon his return to Stockholm in 1755, led to the eſtabliſhment of inoculation houſes in different parts of Sweden. In 1757, the benefits of inoculation were commemorated by a medal.

Inoculation was firſt introduced at Geneva in 1751, whence it paſſed into Switzerland in 1753. In the latter country, it was firſt performed at Lauſanne by a lady on her own child.

Inoculation commenced in Italy during the great mortality occaſioned in Tuſcany and Rome by the ſmall-pox in 1754. Dr. Peverini was the firſt inoculator, putting out of conſideration the cuſtom which had long prevailed in the interior of the country, of women ſometimes artificially communicating the ſmall-pox to their children. In 1755, M. de la Condamine was at Rome, where, by his writings and perſonal influence, he ſucceeded in reconciling many to the practice. Before 1765, inoculation was practiſed with ſucceſs at Venice, Padua, Verona, Breſcia, Mantua, Bologna, Milan, Parma, &c. In ſhort, Naples was the only important place where the method had not been introduced.

Inoculation was begun at Hanover almoſt as ſoon as in England. The oppoſition of De Haen, however, kept back the improvement in moſt other parts of Germany. The Pruſſians and Auſtrians were the laſt to adopt it. At Vienna, inoculation did not make any progreſs till 1765. The younger branches of the imperial family were inoculated in 1768, and ſhortly afterwards the emperor eſtabliſhed an inoculation hoſpital in the ſuburbs of Vienna.

Owing to ſome unfortunate events of the firſt inoculations at Berlin, the practice was ſoon diſcountenanced in Pruſſia, nor was it revived till 1774, when Dr. Baylies was invited from Dreſden to ſuperintend the method.

Although ſome perſons had been inoculated in Livonia by Dr. Schulenius at an earlier period, the practice was unknown at St. Peterſburgh till 1768, when it was eſtabliſhed there under baron Dimſdale. This event muſt have been to the Ruſſians an immenſe bleſſing, ſince in their country, the natural ſmall-pox uſed to rage with ſuch ſeverity, that it is ſaid to have annually deſtroyed two millions of ſubjects. On the 28th of July, 1768, baron Dimſdale inoculated the empreſs and the grand duke, both of whom ſpeedily recovered.

The practice made rapid progreſs; an inoculation hoſpital was eſtabliſhed; and at length Dimſdale returned to England loaded with wealth and honours.

In Spain, inoculation was not extenſively adopted before 1771, though it had been introduced by a ſurgeon forty-two years before at Jadrique, a ſmall town in that kingdom, and had not been diſcontinued in that particular place. Dr. Don Miguel Gorman viſited London for the purpoſe of learning the Suttonian method of inoculation, and returned to Madrid in 1772, where he practiſed the art upon ſeveral of the nobility to the great ſatisfaction of the court.

Of the Objections which were urged againſt Inoculation.—Having related the riſe and firſt progreſs of inoculation in ſeveral parts of the world, it ſeems proper, before reciting the particular methods purſued by the Suttons and baron Dimſdale, to notice the various objections and arguments which were adduced for the purpoſe of ſuppreſſing the practice of inoculation altogether. The clamour againſt the method, indeed, was for many years exceſſively violent; both phyſical and moral reaſons were brought forward againſt the ſyſtem, and men of different profeſſions entered into the controverſy.

1. To the objection that inoculation did not produce the genuine ſmall-pox, and conſequently could not ſecure any one from having the diſeaſe afterwards, the celebrated Dr. Mead made the following judicious reply. "Now I own I cannot underſtand how contagion, that is the very ſeed of the diſeaſe, ſhould produce not its own proper diſtemper, but another of a different kind. Neither, certainly, does it matter by which way the infection is received, provided it brings forth manifeſt marks of the diſeaſe. And as to thoſe, who, after having been inoculated with ſucceſs, are, notwithſtanding this, ſaid to have ſuffered the ſmall-pox, I muſt proteſt that, after the moſt diligent enquiry, I have not been able to find out one convincing proof of this kind. But to ſpeak plainly, if ſuch a thing happened once, why do we not ſee it come to paſs oftener? Or, what can a ſingle example, ſuppoſing it to be true and certain, avail, when innumerable have produced nothing like it?"

2. One formidable objection was, the ſuppoſed danger that inoculation might be the means of communicating other terrible and fatal diſeaſes, when the matter was taken from unhealthy ſubjects. The variolous matter being a poiſon *ſui generis*, it cannot by inoculation communicate any other diſtemper. The venereal diſeaſe is known to be as communicable as any, yet ſeveral perſons have been inoculated from patients labouring under conſiderable degrees of the venereal diſeaſe, and no ill conſequences were ever yet known to follow. Mr. Burgeſs informs us that he knew of one inſtance where the matter was inadvertently taken by a ſurgeon from a young woman, who fell ill of the ſmall-pox, after being admitted into St. Thomas's hoſpital to be ſalivated. Three patients were inoculated from this matter, and had the ſmall-pox in the moſt favourable manner. Nothing particular happened about the wounds, and the patients all grew up healthy ſubjects. See Burgeſs's "Account of the Preparation and Management neceſſary to Inoculation, 1754." Dr. Kirkpatrick alſo mentions in his "Analyſis of Inoculation," that he was aſſured by a reſpectable ſurgeon, that a young lady was inoculated by an apothecary from a gentleman's ſervant, who had a venereal bubo together with the ſmall-pox. The lady, notwithſtanding, did very well, and never had the ſlighteſt ſymptom of venereal infection. The aſſertion, then, that other diſeaſes may be communicated by inoculation remains quite unproved. That other diſeaſes may follow the ſmall-pox no man of common ſenſe will deny; for it is no ſecurity againſt them. Nay, the debility which it ſometimes induces, may even promote the acceſſion of ſcrofula, conſumption, &c.; but ſince inoculation tends ſo materially to diminiſh the ſeverity of the ſmall-pox, it muſt alſo have a great effect in leſſening and preventing any circumſtances, which are to be regarded as conſequences of ſuch ſeverity.

3. Perhaps the diſeaſe may never attack in the natural way. This objection, one would think, muſt give way to the bare ſtatement, that, previous to the practice of inoculation, the caſual ſmall-pox annually deſtroyed about two millions of lives in the Ruſſian empire alone, and committed equal devaſtation in ſeveral other parts of the world. It has been obſerved by Dr. Jurin, in an ingenious paper inſerted in the Philoſophical Tranſactions, that it is difficult to aſcertain the exact number who die without having the ſmall-pox; but that of all the children that are born, there will, ſome time or another, die of the ſmall-pox one in fourteen; and that of perſons of all ages taken ill of the ſame diſtemper, two in eleven will fall victims to it.

From a table of burials it appears that in Edinburgh and St. Cuthbert's pariſh, during ten years, about one-tenth of the dead was killed by the ſmall-pox.

It may likewiſe be noticed, that no individual is originally unſuſceptible of the ſmall-pox, and though a proportion of mankind might poſſibly eſcape the contagion, ſtill the number of victims to the diſorder caſually taken would be very conſiderable. During the controverſies concerning the advantages and diſadvantages of inoculation, enquiries were made from houſe to houſe, in ſeveral towns, in order to aſcertain the number of people, who had had the ſmall-pox in one twelvemonth, when it appeared that nearly one died in every five who had taken the diſeaſe; and that of eighty-two perſons who were inoculated in theſe places in the ſame year, not one died.

Dr. Nettleton, Dr. Whitaker, and ſome others, made an attempt to find out how many perſons had had the ſmall-pox, and how many had died of it in the year 1722. The reſult was as follows:

	Sick of the Small-pox.	Died.
In ſeveral towns in Yorkſhire	3405	636
Chicheſter - -	994	168
Haverfordweſt - -	227	52
Total -	4626	856

This table will ſerve to depict the general event of the caſual ſmall-pox. The mortality was conſiderable; but it was even much greater at ſome periods, and in particular parts of the world. On the other hand, inoculation has ſometimes been purſued with ſuch remarkable ſucceſs, that out of a thouſand perſons inoculated one after the other, ſcarcely one has periſhed.

We ſhall not ſwell this article with a detail of the numerous phyſical reaſons urged againſt inoculation, the preſent ſtate of knowledge renders ſuch a taſk unneceſſary; and all the objections alluded to, have been ſo often and completely proved to be frivolous and unfounded, that of late years the practice has encountered no oppoſition, if we put out of preſent conſideration the praiſeworthy endeavours to ſubſtitute every where the vaccine for the variolous inoculation.

4. The moral and religious objections which were adduced againſt the practice of inoculation, gave riſe to as much d pute as the medical differences of opinion, and c operated ſtill more perniciouſly in prejudicing th

people againſt the art. The plan of bringing diſeaſes upon ourſelves, was repreſented as a Circaſſian impiety, altogether irreconcileable to a Chriſtian conſcience. Thoſe who adopted the practice were branded with the appellations of poiſoners and murderers, and were ſaid to be inſtigated by atheiſm, quackery, and avarice. One anonymous writer implored the interference of parliament. He obſerves, " while this helliſh principle has ſo much hold upon mankind, 'tis highly neceſſary that there ſhould be no doors left open for the practice, at leaſt none that can be ſhut; that there ſhould be no room for the covering of ſuch horrid things from the reach of the law. Phyſicians they have already too much latitude in practice, to make havoc of mankind for the ſatisfaction of their judgment in phyſic, and increaſe of their experience; but every quack now may be a hireling to the devil, and, like that banditti in Italy, be ready to do the drudgery of removing heirs, and other obſtructing incumbents of many kinds, and to do this under the maſk of a cure, inoculating death inſtead of a diſeaſe, and making uſe of an art never before practiſed, in a manner not foreſeen, and by the laws not yet ſufficiently guarded againſt." See a pamphlet entitled " The new Practice of Inoculation conſidered, and an humble Application to the approaching Parliament for the Regulation of that dangerous Experiment, 1722."

A ſermon was preached on Sunday, July 8th, 1722, againſt inoculation, at St. Andrew's church, Holborn, by the Rev. Mr. Maſſey. His text was " So went Satan forth from the preſence of the Lord, and ſmote Job with ſore boils from the ſole of his foot unto his crown," chap. ii. v. 78. In this diſcourſe, the Devil was depicted as having firſt put inoculation in practice upon Job. Inoculation was ſtigmatized as a diabolical operation, and an anti-providential project, that inſults our religion, and baniſhes providence out of the world.

It is almoſt unneceſſary for us to ſay, that Job's being afflicted with the ſmall-pox was nothing more than an unwarrantable aſſertion, and a whimſical conceit of the Rev. Divine. The following epigram on the ſubject appeared in the Monthly Miſcellany for March 1774.

> We're told, by one of the black robe,
> The Devil inoculated Job;
> Suppoſe 'tis true, what he does tell,
> Pray neighbours, *did not Job do well?*

Dr. Wagſtaffe had aſſerted, that it never came into men's heads to take the work out of nature's hands, and raiſe diſtempers by art in the human body. (See " Letter ſhewing the Danger and Uncertainty of inoculating the Small-pox.") To this Mr. Maitland replied in his Vindication, " that the practice of phyſic is founded upon the principle of curing *natural* by raiſing *artificial diſeaſes*. What is bleeding, but an artificial hemorrhagy; purging, but raiſing an artificial diarrhœa? Are not bliſters, iſſues, and ſetons, artificial impoſthumations?"

The virulence and ſarcaſm by which the oppoſers of inoculation were actuated, are well exhibited in the rejoinder, made by another writer, to the foregoing very ſenſible obſervation. " Very good, ſir, but go on,—what is correction at the cart's tail, but the noble art of muſcular phlebotomy? What is burning in the hand, but the art of applying a cauſtic? What is hanging but an artificial quinzy, which makes the patient feel for the ground, and chokes him? What is breaking on the wheel, but the art of making diſlocations and fractures, and differs from the wounds and amputations of ſurgeons only by the manner and intention? —A Short and Plain Account of Inoculation, &c. by I. Maſſey.

Dr. Maddox, biſhop of Worceſter, was an able and zealous friend to the cauſe of inoculation, and preached an excellent ſermon in ſupport of the practice. He obſerved, that it was needleſs to enter into a diſquiſition, which is the moſt proper method of deſignedly raiſing the ſmall-pox in the human frame, by carrying the perſon that is to receive it to the contagious ſteams, or effluvia; or bringing to him the infected matter. Religious difficulties (if any ſtill remain, concerning a practice that has preſerved ſo many lives, and prevented the heavieſt grief in ſo many families,) are exactly the ſame, in either method of voluntary communication.

For it is no more invading the prerogative of heaven to occaſion one eaſy and voluntary conveyance of the infection than another, by a ſlight and hardly ſenſible raſure upon the arm, than communicating the ſame diſtemper, by inviſible particles, to that tender organ the lungs, which are ſo frequently affected by the venom of this diſeaſe, when contracted by the breath, or receiving into the body infected particles in what is called the natural way.

Were this preventive method (continues the learned prelate) univerſally ſucceſsful, and never once to fail in any inſtance whatſoever, it is ſcarcely to be preſumed that any objection would be raiſed againſt a ſalutary expedient, to preſerve from deſtruction ſo great a part of the human ſpecies as daily fall by this mortal enemy, when it attacks men as it were in the dark, ignorant of, and unprepared for the aſſault.

This method of inoculation would then be no more liable to cenſure than the making a voluntary wound, by inciſion, to form a neceſſary drain; or adminiſtering any operative medicine, which, upon repeated trials, had proved an unfailing ſecurity againſt any other dangerous and prevailing peſtilence or contagion.

But, in order to excite and ſecure a dependence upon his divine providence, the great Governor of the world has appointed that no human affairs, not even our neceſſary ſuſtenance, ſhould be attended with ſuch abſolute certainty: a very wiſe appointment, that vain man might not fancy himſelf an independent being; but, among all the changes and chances of this mortal life, ſhould ſtill look up unto, becauſe he can only be defended by, God's moſt gracious and ready help.

Experience alone muſt determine the good or bad conſequences of this artificial infection, as it ought to do in all other medical attempts, which, in many inſtances, are, in reality, little more than curing or alleviating one diſtemper, by exciting or introducing another. And, in this view, the method now under conſideration, of leſſening the hazard of a very mortal diſeaſe, ſhould be conſidered in the ſame light as every other antidote, or preventive attempt in phyſic or ſurgery, againſt any probable, almoſt certain malady, internal or external.

The philanthropic prelate forebore to derive any ſtrength to the argument, from the great number of noble, venerable, and worthy perſons, of every rank and profeſſion, who were in his time the public advocates of this compaſſionate deſign: he wiſhed to ſtand upon its own proper evidence and foundation.

He remarked, that a ſafe paſſage through this diſtemper, like the emancipating ſlaves, is a deliverance to vaſt numbers of people kept, as it were, in bondage; who, before they have undergone this abhorred diſeaſe, are excluded from many offices in life, and prevented from purſuing their neceſſary buſineſs; and it gives tranquillity and cheerfulneſs to to perſons of better condition, who, under apprehenſion of this loathſome and infectious diſorder, were all their former days ſubject to great anxiety and conſtant fear.

The biſhop commented with great ability upon the advantage that inoculation affords of communicating the ſmall-pox at the moſt favourable time of life, *viz.* infancy, when the diſeaſe is moſt inclined to put on a mild form. He mentioned, authentically, that, out of 1500 perſons inoculated by Mr. ſerjeant Ranby, Mr. ſerjeant Hawkins, and Mr. Middleton, only three died.

He ſtated to his congregation, that, from the annual account within the bills of mortality, (in which many places in and near the city were omitted,) it appeared that, in twenty years, *viz.* from the year 1731 to the year 1750, incluſive, no leſs than 39,115 perſons died of this fatal diſtemper; which, including the places not inſerted in the weekly bills, muſt have been conſiderably more than 2000 every year, that fell in the two adjoining cities and parts adjacent. And, he noticed, that if only one in ſeven is ſuppoſed to die by the diſtemper taken in the natural way, then the whole number of perſons who, in this period of twenty years, were thus infected, muſt have amounted to 280,000, of which number no leſs than 40,000 periſhed. But if one in every 200 ſhould be ſuppoſed to die under inoculation, which is really more than fall by that artificial infection, inſtead of 40,000, only 1400 would have died in one diſtrict in twenty years, had inoculation been univerſally adopted. Thus the difference in that ſhort period, in one ſpot, would have been no leſs than 38,600 lives preſerved, beſides the numerous poſterity that might have been derived from them.

The learned divine inſiſted, that humanity, regard to our country, the dictates of reaſon, and the precepts of religion, are all in favour of the ſyſtem of inoculation.

During the oppoſition to the introduction of inoculation, many affected to be actuated againſt it by religious ſcruples, and the practice was alleged to be unlawful.

In anſwer to this, the ſcriptures aſk, Is it lawful to ſave life, or to deſtroy it? Luke, vi. 9. We ſhould alſo remember, that, as the fall of man brought the danger of diſeaſes into the world, ſo to evade, oppoſe, or deſtroy it, is not only his right, but duty, if in his power. When danger ſurrounds us, no conduct is more proper than to inquire into, and purſue the means of eſcape. To neglect our ſafety is to ſink below brutes, which are taught by inſtinct to ſhun the evil to which they are expoſed. Inoculation is certainly in many inſtances a means of ſaving life, and of moderating the ſeverity of affliction. And, in a moral point of view, wilfully neglecting the means of preſerving life muſt appear almoſt as bad as the guilt of murder.

The bringing of a diſtemper on ourſelves was likewiſe repreſented by bigotted individuals as uſurping the ſacred prerogative of God.

As to the firſt part of this objection, if by diſtempers are meant ſickneſs and pain, the ſame thing is practiſed daily in other inſtances, in concurrence with the ſcripture dictate, *viz.* of two evils chooſe the leaſt. Inoculation is not done from a mere wanton deſire of imparting any diſeaſe, but is performed in order that the patient may go through an unavoidable diſtemper with the leaſt difficulty, and the greateſt chance of recovery. The natural ſmall-pox being highly perilous, it muſt be a great deſideratum to avoid it, and inoculation enables us to do ſo, by deſtroying that diſpoſition in the body, without which the diſeaſe cannot take place.

Reſpecting the offence given to God, a reliance on providence does not imply that we are not to prevent or oppoſe the evils which we foreſee, and which we have it in our power to guard againſt by prudent precautions. Would theſe objectors, in other inſtances, refuſe the means of leſſening the malignancy and danger of diſeaſe, than which the practice of inoculation is no more? Let the aſſertors of the rights of God ſay, whether, when God permits the diſcovery of preſerving ourſelves, he forbids our uſing it? If our Maker offers us a remedy, it is offending him to reject it.

It was moreover objected, that the decrees of God have fixed the commiſſion of every diſeaſe, and that our precaution cannot prevent what He has determined.

To this it was anſwered, that, however true it is, our days are determined, &c. yet it is God's revealed will, and not his ſecret purpoſes, which we are to regard as the rule of duty. God has required of us to have a tender regard of our lives; and they who diſobey him therein are guilty of a degree of ſelf-murder, and will never be acquitted of that guilt by the ſecret determination of Heaven concerning them. Beſides, God, who has ordained the end, has alſo determined the means leading to it. St. Paul, in his dangerous voyage, had a ſpecial revelation to aſſure him, that all who were with him ſhould eſcape; and yet, when the ſeamen were getting out of the ſhip, he declares, that if they did not ſtay in it they could not be ſaved. Acts, xxvii. 31. God purpoſed to preſerve them in the way whereby they were afterwards delivered.

It was likewiſe contended that we ought not to do evil, that good may come.

On the other hand, it was acknowledged, that if inoculation is, in its own nature, a moral evil, it certainly ſhould be rejected, however great its advantages may ſeem to be. The proſpect of relief from any calamity in life ſhould not tempt us to offend God. But they who make the foregoing objection proceed upon a miſtake. Their principle is true with regard to moral evil, but is not ſo when applied to phyſical. It is certainly lawful to pull down one houſe to ſave a great number from being burnt. This is a phyſical evil, which can hardly take place without ſome degree of moral evil; and many other inſtances may be pointed out, where, for a greater good, a leſſer ill is ſubmitted to.

It was further objected, that the patient might die, and then his laſt moments would be diſtreſſed, and the future reflections of his friends grievous.

This objection led many to decline the practice of inoculation, even while they allowed the theory of it to be reaſonable. They entertained hopes of eſcaping the diſtemper in the natural way, and they had fears of dying in this, and thus they were prevented from undergoing the diſorder. But they ſhould have conſidered what grounds they had for either their hopes or fears, and what was to be advanced to balance the account, in an examination of the different degrees of probability attendant on what they hoped for, and what they were afraid of, in the neglect or adoption of inoculation. Dying is an awful thing; but if inoculation was a *probable and lawful* means of preſerving life in a time of danger, it was a duty to comply with it; and what reflection could be more peaceful than that of dying in the way of duty?

It was further objected by the religious oppoſers of the new practice, that fear was a dangerous paſſion in the ſmall-pox, and that inoculation increaſed the cauſes of fear, by leſſening our faith and truſt in God.

When the ſmall-pox was left to nature, ſuch were its ravages, that, not to fear, would have been to ſink beneath humanity: its conſequences were too grievous to be viewed with indifference. Experience manifeſted the advantages and general ſafety of receiving the diſeaſe by inoculation, and ſo far the practice was a remedy to that juſt alarm which enhanced the danger, when the diſtemper was left to itſelf. As to faith in God, none was deſirable, except that which was agreeable to the ſcripture, and which could never have the effect of creating a diſregard to calamities and danger. Inoculation was well proved to be a means of ſafety, and it would have been as rational to conclude that our lives could be preſerved without eating and drinking, as that we ſhould be delivered from danger without a prudent care for our own ſafety. We are to depend on the care of providence only in the way of duty. To boaſt of courage and truſt in God, while we omit the means of eſcaping danger which ſurrounds us, is not faith but preſumption.

Thus, when inoculation became a probable means by which life might be ſaved, the neglect of it, ſo far from being truſt, was preſumption.

We ſhall now take our leave of theſe theological diſputes and ſcruples, which have now been long removed by the influence of right reaſon and ſound ſenſe. When it was once well aſcertained and univerſally believed that inoculation was really a means of preſerving life, the idea of its being criminal to adopt the practice could not have much duration. A very able diſcuſſion of moſt of the foregoing objections was publiſhed in a pamphlet, entitled "Inoculation impartially conſidered, and proved to be conſiſtent with Reaſon and Revelation," by the Rev. David Some, edited by Dr. Doddridge, 1750.

Of Inoculation, as practiſed by the Suttons, Baron Dimſdale, &c.—The introduction of the Suttonian practice was regarded quite as a new era in the hiſtory of inoculation, from the novelty of the method, and its unparalleled ſucceſs.

Mr. Robert Sutton, the firſt of this name, who acquired celebrity as an inoculator, reſided at Debenham in Suffolk, where he practiſed ſurgery and pharmacy. From the year 1757 to 1767, he inoculated 2514 perſons.

Two of his ſons, Robert and Daniel, followed the medical profeſſion, and after aſſiſting him during the three firſt years of his practice of inoculation, Robert eſtabliſhed himſelf as an inoculator at Bury St. Edmund's, while Daniel became aſſiſtant to Mr. Bumſtead, a ſurgeon at Oxford. Daniel, on his return to Debenham, in the year 1763, ſuggeſted to his father a new plan of inoculation, in which he propoſed to ſhorten the time of preparation to a few days, and not to confine the inoculated patients to the houſe, but to oblige them to be in the open air as much as poſſible during the whole progreſs of the diſtemper.

The father condemned this ſcheme as raſh and dangerous. Its advantages, however, ſoon becoming manifeſt to patients, they evinced a deſire of being ſolely under the management of Mr. D. Sutton. The conſequence was, that the father and ſon ſeparated about the end of the year 1763, when the latter opened an inoculating-houſe near Ingateſtone, in Eſſex. Here, by public advertiſements, he made known his plan of inoculating in an improved way peculiar to himſelf. The encouragement which he met with may be eſtimated from his receiving, during the firſt year, 2000 guineas, and above 6000 the ſecond. His fame ſpread to the moſt diſtant parts of the kingdom; and the numbers that reſorted to him for inoculation, conſtantly filled the village of Ingateſtone, ſo that accommodations could hardly be procured for the purpoſe. His practice in Kent being alſo very extenſive, he was obliged to employ ſeveral medical aſſiſtants. In 1767, Mr. D. Sutton removed to London, in hopes of reaping ſtill more emolument; but his receipt fell far ſhort of his expectation.

According to Mr. Houlton's ſtatement, the number of perſons inoculated by Mr. Daniel Sutton in the year

1764 was 1629
1765 — 4347
1766 — 7816

13,792

"To the above number," ſays he, "ſhould be added 6000 that have been inoculated by Mr. Sutton's aſſiſtants; ſo that he may be ſaid to have inoculated, within theſe three years, 20,000 perſons."

Of this number, not one was allowed to have fairly died of inoculation. The venal pen of the preceding writer certainly exaggerated every thing, and great boaſt was alſo falſely made of the Suttons having a ſpecific medicine for preventing too many puſtules. However, no doubt was entertained that the Suttonian practice was incomparably more ſucceſsful than any other.

Medical practitioners, ſtruck with the advantages of the new treatment, ſet about the inveſtigation of the cauſes. Sir George Baker publiſhed the following account of the manner in which Mr. D. Sutton practiſed inoculation: "All perſons are obliged to go through a ſtrict preparatory regimen for a fortnight before the operation is performed. During this courſe, every kind of animal food, milk only excepted, and all fermented liquors and ſpices are forbidden. Fruit of all ſorts is allowed, except only on thoſe days when a purging medicine is taken. In this fortnight of preparation, a doſe of a powder is ordered to be taken at bed-time, three ſeveral times; and on the following morning a doſe of purging ſalt. To children, only three doſes of the powder are given, without any purging ſalt. The compoſition of this powder is induſtriouſly kept a ſecret. But, that it conſiſts partly of a mercurial preparation, is demonſtrated by its having made the gums of ſeveral people ſore, and even ſalivated others. The months of May, June, July, and Auguſt, are preferred as the moſt ſeaſonable for inoculation. But healthy people are inoculated at any ſeaſon of the year indifferently. The autumn is held to be the worſt ſeaſon; and an aguiſh habit the leaſt proper for this operation. No objection is made to any one on account of what is vulgarly called a ſcorbutic habit of body, or bad blood. The perſon who is to be inoculated, on his arrival at the houſe uſed for this purpoſe, is carried into a public room, where, very probably, he may meet a large company aſſembled under the ſeveral ſtages of the ſmall-pox. The operator then opens a puſtule of one of the company, chuſing one where the matter is in a crude ſtate; and then juſt raiſes up the cuticle on the outer part of the arm, where it is thickeſt, with his moiſt lancet. This done, he only preſſes down the raiſed cuticle with his finger, and applies neither plaſter nor bandage. What is extremely remarkable, he frequently inoculates people with the moiſture taken from the arm before the eruption of the ſmall-pox, nay, within four days after the operation has been performed. And," ſays ſir G. Baker, "I am informed, at preſent he gives the preference to this method. He has attempted to inoculate by means of the blood; but without ſucceſs. If the operator happeneth not to be at home when the new patient arriveth, this is looked upon as a matter of no importance. And ſo far is he from any apprehenſion of accumulating infection, that it is very common for perſons, juſt inoculated, to lie in the ſame bed with a patient under any ſtage of the diſeaſe, as it may happen; nay, ſometimes in a room where four or five people are ſick. On the night following the operation, the patient takes a pill. This medicine is repeated every other night, until the fever comes on. All this time, moderate exerciſe in the air is ſtrongly recommended. In twenty-four hours after the inoculation, the operator can often diſtinguiſh whether or no the patient be infected. He every day examines the inciſion; and from hence ſeems to prognoſticate, with ſome degree of certainty, concerning the degree of the future diſeaſe. In three days after the operation (provided that it has ſucceeded), there appears on the inciſion a ſpot like a flea-bite, not as yet above the ſkin. This ſpot, by degrees, riſes to a red pimple; and then becomes a bladder full of clear lymph. This advanceth to maturation like the variolous puſtules, but is the laſt which falleth off. In proportion as the diſcolouration round the place of the inciſion is greater, the leſs quantity of eruption is expected. And, therefore, whenever only a ſmall diſcoloured circle is obſerved, purging medicines, more than ordinary, and more frequently repeated, are held to be neceſſary.

"The preparatory diet is ſtill continued. If the fever remains ſome hours without any tendency to perſpiration, ſome acid drops are adminiſtered, the effect of which is to bring on a profuſe ſweat; but in ſome caſes where the fever is very high, a powder or pill, ſtill more powerful, is given. In general, during the burning heat of the fever, the inoculator gives cold water. But the perſpiration beginning, he orders warm balm-tea or thin water-gruel. As ſoon as the ſweat abates, the eruption having made its firſt appearance, he obliges every body to get up, to walk about the houſe, or into the garden. From this time, to the turn of the diſeaſe, he gives milk gruel, *ad libitum*.

"On the day following the firſt appearance of the opaque ſpot on the puſtules, to grown people he gives an ounce of Glauber's purging ſalt. To children he gives a doſe of it proportioned to their age. Then, if the eruption be ſmall, he allows them to eat a little boiled mutton, and toaſt and butter, and to drink ſmall beer. But in caſe of a large eruption, he gives them, on the third day after their having taken the firſt doſe, another doſe of the ſame ſalt, and confines them to the diet ordered during the preparation."

Sir George, after repreſenting this as the practice of Mr. D. Sutton, aſcribes its ſuperior ſucceſs to the free uſe of cold air. Dr. Glaſs, of Exeter, in a publication which appeared ſhortly after that of the preceding gentleman, imputed the advantages of the Suttonian method to the patient being ſweated; while another author, Mr. Chandler, differed from both the former writers, and referred the chief benefit of the plan to the infecting humour being taken in a crude ſtate, "before it has been ultimately variolated by the ſucceeding fever." Baron Dimſdale likewiſe thought, that lthough the whole proceſs might have ſome ſhare in the production of the ſucceſs, yet he believed the chief good was owing to the method of inoculating with recent fluid matter, and the management of the patients at the time of he eruption.

In November, 1766, baron Dimſdale publiſhed his well known work, entitled "The preſent Method of inoculating for the Small-pox." The inſtructions contained in this book have deſervedly continued ever ſince, almoſt without exception, to regulate the practice of inoculation.

The baron, when the age is left to his choice, avoids inoculating children under two years of age. The ſubjects conſidered by him improper for the operation, are ſuch as abour under any acute or critical diſeaſes, or their effects; nd alſo ſuch as have evident marks of corroſive acrimonious humours, or manifeſt debility.

As for the moſt eligible ſeaſon of the year, he thought, hat perſons generally had more puſtules in the ſpring than ny other time; and epidemic diſeaſes (eſpecially fluxes, intermittents, and ulcerated ſore throats) being moſt frequent in the autumn, the baron did not look upon this as in general the moſt favourable ſeaſon. But he was of opinion, that we might ſafely inoculate at all ſeaſons, provided care were taken to ſcreen the patients as much as poſſible from heat in ſummer, and to prevent them from keeping themſelves too warm, and too much ſhut up from the weather in winter. He thought it prudent, however, to avoid inoculation while any peculiar epidemic diſeaſes were prevalent. He recommended a preparatory regimen, ſo as to reduce the patient, if in high health, to a low and more ſecure ſtate; to ſtrengthen the conſtitution if too low, to correct what appears vitiated; and to clear the ſtomach and bowels as much as may be from all crudities and their effects. Young or middle aged perſons, enjoying a good ſtate of health, were ſtrictly confined to a milk and vegetable diet for nine days previous to the operation, during which period they were ordered to take the following powder three times at bed-time, and a doſe of Glauber's ſalt each ſucceeding morning. The powder was compoſed of eight grains of calomel, the ſame quantity of compound powder of crabs' claws, and $\frac{1}{6}$th of a grain of emetic tartar. For women or children the doſe was leſſened, according to their age and ſtrength. For thoſe who were of a tender delicate conſtitution, or valetudinarians, he preſcribed a milder medicine, and rather of the alterative than the purgative kind; indulging ſome with light animal food, and in caſe of lowneſs, with a glaſs or two of wine. The baron preferred the following method of inoculating. The patient to be infected being in the ſame houſe, and if no objection is made to it, in the ſame room with one who has the diſeaſe, a little variolous matter is taken from the place of inſertion, if the ſubject is under inoculation, or a puſtule, if in the natural way, on the point of a lancet, ſo that both ſides of the point are moiſtened. With this lancet an inciſion is made in that part of the arm where iſſues are uſually placed, deep enough to paſs through the ſcarf-ſkin, and juſt to touch the ſkin itſelf, and in length as ſhort as poſſible, not more than one-eighth of an inch. The little wound being then ſtretched open between the finger and thumb of the operator, the inciſion is moiſtened with the matter by gently touching it with the flat ſide of the infected lancet. The baron generally performed the operation in both arms, and ſometimes in two places in one arm, a little diſtance from each other. Neither plaſter nor bandage is to be applied to the inoculated part. The baron preferred uſing ſuch matter as was taken during the eruptive fever, it being then in his opinion endued with moſt activity. When the diſeaſe was to be communicated from an inoculated perſon, he took the matter, not from the ſecondary puſtules, but from the place of inoculation. The ſecond day after the operation, if the inoculated part is viewed with a lens, he ſays, there generally appears a kind of orange-coloured ſtain about the inciſion, and the ſurrounding ſkin ſeems to contract. At this time the baron uſed to preſcribe the following medicine to be taken at bed-time: calomel and compound powder of crabs' claws, of each three grains, emetic tartar $\frac{1}{10}$th of a grain. On the fourth or fifth day a hardneſs is perceptible to the finger. The part itches and appears ſlightly inflamed. He remarks, that a little clear fluid may be ſeen under a kind of veſication, the part reſembling a ſuperficial burn. In general, about the ſixth day ſome pain and ſtiffneſs are felt in the arm-pit. This was regarded as a very deſirable ſymptom, as foreboding the near approach of the eruptive ſymptoms, and the favourable progreſs of the diſeaſe. Sometimes on the ſeventh, more often on the eighth day, the ſymptoms of the eruptive fever appear; ſuch as ſlight remitting pains in the head and back, ſucceeded by tranſient ſhiverings and alternate heats, which continue in a greater or leſſer degree till the eruption is perfected.

The inflammation in the arm at this time ſpreads faſt, and upon viewing the inciſion with a good glaſs, it appears for the moſt part ſurrounded with an infinite number of ſmall puſtules, which increaſe in ſize and extent as the diſeaſe advances. On the tenth or eleventh day a circular or oval effloreſcence is uſually diſcovered ſurrounding the inciſion, and extending ſometimes nearly half round the arm, but more frequently to about the ſize of a ſhilling, and, being under the cuticle, is ſmooth and not painful. This effloreſcence was alſo regarded as favourable; it accompanies the eruption, every diſagreeable ſymptom ceaſes, and the pain and ſtiffneſs in the axilla go off.

When the eruptive ſymptoms came on with more ſeverity, baron Dimſdale uſed to direct a repetition of the laſt-mentioned powder, and on the following morning three or four ſtools were procured by a laxative draught.

The baron notices that ſometimes the ſtate of the inciſion is ſuch for ſeveral days, that the effects of the inoculation can barely be perceived, the colour about the wound remaining pale inſtead of changing to red; the edges of the inciſion ſpread but little, they remain flat, and are attended neither with itching nor uneaſineſs of any kind. Nay, ſometimes on the fifth, and even on the ſixth day, the alteration is ſo little, as to make it doubtful whether the infection has taken place. Dimſdale ſets down ſuch appearances as unfavourable, and implying a late and more untoward diſeaſe. To prevent this, he uſed to direct the powder or pill to be taken each night, and in caſe it failed to operate by ſtool, or there was the leaſt diſpoſition to coſtiveneſs, an ounce of Glauber's ſauce, or a laxative draught, was given in the morning, once or twice, as the caſe might require. The baron believed that theſe meaſures forwarded the inflammation, which he always wiſhed to ſee, as he had conſtantly obſerved, that an early progreſs on the arm, and an early commencement of the eruptive complaints, portended that the diſtemper would be mild and favourable; and on the contrary, that when both were late, the ſymptoms proved more irregular and untoward. The patient, inſtead of being confined to his bed or room, when the ſymptoms of the eruptive fever came on, was directed, as ſoon as the purging medicine had operated, to keep abroad in the open air, be it ever ſo cold, as much as he could bear, and to drink cold water, if thirſty, always taking care not to ſtand ſtill while abroad, but to walk about with moderation.

In certain caſes, notwithſtanding baron Dimſdale found the eruptive ſymptoms extremely violent, and the patients almoſt incapable of motion, and apprehenſive of cold as the greateſt evil, yet he perſuaded them to riſe out of bed and go out of doors, often ſupported by aſſiſtants, and he allowed them to drink as much cold water as they choſe. No ſiniſter accident was the conſequence, but, on the contrary, the patients' ſpirits were revived, and every ſymptom ſeemed benefited by the method.

When any uncommon languor happened, a baſin of thin broth, or a glaſs of wine, was allowed in the day, or ſome white-wine whey at bed-time. Indeed, ſuch things were allowed at any time to tender, aged, or weakly perſons. After the eruption was completed, if occaſion required, they were indulged in a little well-boiled meat of the lighteſt kind, as chicken, veal, or mutton.

The practice of baron Dimſdale was certainly, in a great meaſure, an imitation of the method purſued by Mr. D. Sutton.

We ſhall conclude this article with a few neceſſary inſtructions and references.

1. The age of the perſon to be inoculated for the ſmall-pox ſhould be as little advanced as poſſible; but (if it can be avoided) not leſs than four months.

2. The matter, when convenient, ſhould be taken from a young ſubject who has the ſmall-pox in a favourable way, and freſh matter ſhould have the preference to ſuch as is old. It deſerves particular attention, however, that it is chiefly for the ſake of avoiding unprofeſſional blame that we chooſe matter from patients labouring under the diſeaſe mildly, ſince experience rather proves, that the lenity or malignity of the ſmall-pox depends very little on whether the matter is taken from one patient who has the diſtemper favourably, or from another who has it ſeverely. Nor can we wonder at this fact, ſince the contagion can only be of one ſort. Therefore, were a patient much expoſed to the caſual ſmall-pox, and no matter could be procured from any ſubject that had the diſtemper mildly, the ſurgeon ſhould recommend inoculation with ſuch matter as it would be in his power to obtain.

3. In inoculating, the operator is to make the ſlighteſt puncture, or ſcratch, imaginable in the arm over the place where the inſertion of the deltoid muſcle terminates. That part of the lancet which is beſmeared with the matter, is to be repeatedly rubbed over the wound, and leſt the matter be wiped away, it is beſt not to pull down the ſhirt-ſleeve till the part is quite dry. Some operators prefer introducing the lancet, armed with the matter, obliquely beneath the cuticle. When this mode is followed, it is proper at the time of withdrawing the lancet to preſs the wound with the finger, ſo that the parts in contact with the matter may wipe it off the lancet with more certainty.

The works on the inoculation for the ſmall-pox are too numerous to be even mentioned: we would, however, particularly refer to Friend's Hiſtory of Medicine. D'Entrecolle's Lettres Edifiantes et Curieuſes. Avicennæ Opera. Mémoires ſur l'Inoculation par M. de la Condamine. Philoſophical Tranſactions for 1722. Monro on Inoculation in Scotland. Inquirendum, *Melius*. See Melius, &c.

INQUISITIO *Poſt Mortem*. See *Inqueſt of* Office.

INQUISITION, in the *Civil* and *Canon Law*, a manner of proceeding for the diſcovery of ſome crime by the ſole office of the judge, in the way of ſearch or examination.

Inquisition is alſo uſed, in *Common Law*, for a like proceſs in the king's behalf, for diſcovery of lands, profits, and the like. In which ſenſe it is alſo confounded with *Office*; which ſee.

Inquisition, or the *Holy Office*, denotes an eccleſiaſtical juriſdiction eſtabliſhed in Spain, Portugal, Italy, &c. for the trial and examination of ſuch perſons as are ſuſpected to entertain any religious opinions contrary to thoſe profeſſed in the church of Rome.

It is called inquiſition, becauſe the judges by their office take cognizance of crimes on common report, without any legal evidence, except what they themſelves are able to explore.

Some people fancy they ſee the original of the inquiſition, in a conſtitution made by pope Lucius, at the council of Verona, in 1184, where he orders the biſhops to get information, either by themſelves, or by their commiſſaries, of all ſuch perſons as were ſuſpected of hereſy; and diſtinguiſhes the ſeveral degrees of ſuſpected, convicted, penitent, relapſed, &c. However this be, it is generally allowed, that pope Innocent III. laid the firſt foundation of the Holy Office; and that the Vaudois, and Albigenſes were the firſt objects of it. That pontiff, in the beginning of the thirteenth century, ſent Rainier, a Ciſtercian monk, and Pierre de Caſtelnau, archdeacon of Maguelonne, to the country of Thouloufe, or Narbonne Gaul, in order to blow up a ſpirit of zeal and perſecution againſt the prelates and princes. Theſe miſſionaries were ſoon followed by others, among whom was the famous Spaniard, Dominic, founder of the order of Preachers, who returning from Rome in the year 1206, fell in with theſe delegates, embarked in their cauſe, and laboured, both by his exhortations and conduct, in the extirpation of hereſy. Theſe ſpiritual champions were to give an account to the pope of the number of heretics in thoſe parts, and of the behaviour of the princes and perſons in authority to them; and thence they acquired the name of inquiſitors: but theſe original inquiſitors had not any court, or any authority, they were only a kind of ſpiritual ſpies, who were to make report of their diſcoveries to the pope, and to excite the Catholic princes and people to extirpate heretics.

It has been generally ſaid, that the tribunal of the inquiſition was the invention of St. Dominic, and firſt erected by him in the city of Thoulouſe; that, conſequently, he was the firſt inquiſitor; and that, although the year of its inſtitution is uncertain, it was undoubtedly confirmed, in a ſolemn manner, by Innocent III. in the council of the Lateran, in the year 1215. See Limborch's Hiſt. of the Inquiſition, by Chandler, book i. chap. 10.

This account is conteſted by Moſheim, who maintains, that St. Dominic was not appointed by the Roman pontiff to proceed judicially againſt heretics, and ſuch as were ſuſpected of hereſy, to pronounce ſentence according to their reſpective caſes, and to deliver over to the ſecular arm ſuch as perſiſted obſtinately in their errors, and therefore, in this ſenſe, was no inquiſitor; though, according to the original meaning of the term, he was inveſted with the commiſſion and authority of the Roman pontiff to extirpate hereſy, and oppoſe its abettors, but without any judicial power: nay, it is farther urged, that the court of inquiſition was not erected during the life of St. Dominic. The horrid war, which was excited by Innocent III. againſt the Albigenſes in Narbonne Gaul, and which was carried on by the croſs-bearers with the utmoſt cruelty from the year 1209 to 1229, when a treaty of peace took place between Raymond VIII. earl of Thoulouſe, and Lewis VIII. king of France, which gave a mortal blow to the cauſe of hereſy, prepared the way for the full eſtabliſhment of the inquiſition.

Inquiſitors of the firſt kind had, in the courſe of this time, been placed in almoſt every city, whoſe inhabitants had the misfortune to be ſuſpected of hereſy, notwithſtanding the reluctance which the people manifeſted to this new inſtitution, and the violence with which they frequently expelled and ſometimes maſſacred theſe bloody officers of the popiſh hierarchy. At length, the council held at Thoulouſe, in the year 1229, by Romanus, cardinal of St. Angelo, and pope's legate, went ſtill farther, and erected in every city a council of inquiſitors, conſiſting of one prieſt, and three laymen. This inſtitution was, however, ſuperſeded in the year 1233, by Gregory IX. who entruſted the Dominicans, or Preaching Friars, with the important commiſſion of diſcovering and bringing to judgment the heretics that were lurking in France; and in a formal epiſtle diſcharged the biſhops of that painful office. Immediately after this, the biſhop of Tournay, who was the pope's legate in France, began to execute this new reſolution, by appointing Pierre Cellan and Guillaume Arnaud, inquiſitors of heretical pravity at Thoulouſe; and afterwards proceeded in every city where the Dominicans had a convent, to conſtitute officers of the ſame kind choſen from among the monks of that order. From this period we are to date the commencement of the dreadful tribunal of the inquiſition, which in this and the following ages ſubdued ſuch a prodigious multitude of heretics, part of whom were converted to the church by terror, and the reſt committed to the flames without mercy. For the Dominicans erected firſt at Thoulouſe, and afterwards at Carcaſſone, and other places, a tremendous court, before which were ſummoned not only heretics, and perſons ſuſpected of hereſy; but likewiſe all who were accuſed of magic, ſorcery, Judaiſm, witchcraft, and other crimes of that kind. This tribunal, in proceſs of time, was erected in the other countries of Europe, though not every where with the ſame ſucceſs. The method of proceeding in this court of inquiſition was at firſt ſimple, and almoſt in every reſpect ſimilar to that which was obſerved in the ordinary courts of juſtice. But the Dominicans modelled it after that of the tribunal, called in the Roman church the tribunal of peace; and hence aroſe that ſtrange ſyſtem of inquiſitorial law, which in many reſpects is ſo contrary to the common feelings of humanity, and the plaineſt dictates of equity and juſtice. And that nothing might be wanting to render the ſpiritual court formidable and tremendous, the Roman pontiffs perſuaded the European princes, particularly the emperor Frederic II. and Lewis IX. king of France, not only to enact the moſt barbarous laws againſt heretics, and to commit to the flames thoſe who were pronounced ſuch by the inquiſitors, but alſo to maintain the inquiſitors in their office, and grant them their protection in the moſt open and ſolemn manner. The edicts iſſued to this purpoſe by Frederic II. are well known; edicts every way proper to excite horror, and which rendered the moſt illuſtrious piety and virtue incapable of ſaving from the moſt cruel death ſuch as had the misfortune to be diſagreeable to the inquiſitors. The laws of Frederic, in relation to the inquiſitors, may be ſeen in Limborch's Hiſtory of the Inquiſition, book i. chap. 12.

The edict of St. Lewis, in favour of theſe ghoſtly judges, iſſued out in the year 1229, is generally known under the title of *Cupientes.*

After the death of Frederic, who had long before repented the power he had given the churchmen, as having ſeen ſome of the fruits of it, pope Innocent IV. erected a perpetual tribunal of inquiſitors, and deprived the biſhops and ſecular judges of the little power the emperor Frederic had left them. And this juriſdiction, which depended immediately upon himſelf, he took care to introduce into moſt of the ſtates of Europe. In 1251 it was eſtabliſhed in Italy; in 1255 Alexander IV. appointed inquiſitors in France, at the requeſt of St. Lewis. But the inquiſitors were ſo fiery hot, and made ſuch horrible butchery among the reputed heretics, that they raiſed an univerſal deteſtation even in ſome Catholic countries themſelves. Hence it was that their reign proved very ſhort both in France and Germany; though they were occaſionally exerting themſelves; and their power was eſtabliſhed in many parts of France and Germany about the time of the Reformation by Luther; but afterwards gradually declined. Nor was even Spain entirely ſubject to them till the time of Ferdinand and Iſabella, when their power was increaſed, under pretence of clearing the country of Judaiſm and Mahometaniſm.

The inquiſition was firſt introduced into Spain in the year 1478; but the firſt inquiſitor-general, and the ſupreme council of the inquiſition, were not fixed till the year 1483. This tribunal is ariſen to ſuch a height in Spain that the king of Caſtile before his coronation ſubjects himſelf and all his dominions, by a ſpecial oath, to the moſt holy tribunal of the inquiſition. It is under the direction of an inquiſitor-general, appointed by the king, and confirmed by the pope; and this inquiſition has power to name particular inquiſitors in every place where there is any tribunal of the inquiſition.

The inquiſition was eſtabliſhed in Portugal, at the preſſing ſolicitation of king John III. about the year 1536: and both the Spaniards and Portugueſe have eſtabliſhed it in their territories in the weſtern continent.

The power of the inquiſition was very much limited in ſome countries, particularly at Venice, where it was introduced about the year 1289, and where it was received under ſuch modifications, as proved a great check on its authority; the office conſiſting of ſecular and eccleſiaſtical perſons, though the latter had been long endeavouring to bring it into their own hands, but could never prevail with the Venetian ſenate to agree to it. Indeed at Venice it ſeemed rather a political than a religious contrivance; and ſerved rather for the ſecurity of the ſtate, than that of the church. There are appeals from the ſubaltern inquiſitions in Italy, to the congregation of the holy office reſiding at Rome.

The congregation was firſt formed by Paul III. in 1542, but finally eſtabliſhed by Sixtus V. in 1588. The members of it, called ſupreme inquiſitors, aſſemble thrice in the week, and every Thurſday in the preſence of the pope, who preſides in it.

The officers or miniſters of the inquiſition are the inquiſitors, who derive their power from the pope, either by word of mouth, or by his apoſtolic letters, and can be removed only by him, or by authority conferred by him on thoſe cardinals who are the inquiſitors-general; vicars-general, who manage the affairs of the inquiſition during the abſence of the inquiſitors; aſſeſſors and counſellors, who give their advice in points of theology and law; the promoter fiſcal, whoſe office it is to examine the depoſitions of the witneſſes, to give information of criminals to the inquiſitors, and to demand their apprehenſion and impriſonment, and, finally, when apprehended and admoniſhed, to accuſe them; notaries or regiſters, who write down the injunctions, accuſations, and all the pleadings of the cauſes; the judge and receiver of the confiſcated effects; the executor and officials, who apprehend and keep in cuſtody criminals; the attendants or familiars; the croſs-bearers; and the viſitors, who viſit all the provinces of the inquiſitors, and report to the inquiſitor-general and council whatever was proper to be amended. The civil magiſtrate is entirely excluded from the cognizance of hereſy; but the inquiſitors require their aſſiſtance for the puniſhment of heretics, in conſequence of the ſentence which they pronounce: and they are ſeverely threatened with the moſt grievous puniſhments, if they neglect their duty. The puniſhments inflicted by the inquiſition on heretics are eccleſiaſtical and civil: the eccleſiaſtical or canonical are excommunication, deprivation of eccleſiaſtical burial, dignities, benefices, and offices. The civil are confiſcation of goods, which is inflicted on all who are convicted of hereſy, or confeſs, whether they repent or perſiſt in their hereſy, becauſe they are declared to incur the puniſhment, *ipſo jure*, as ſoon as they fall into hereſy; diſinheriting the children, inſomuch that though they are Catholics, they can never inherit the eſtates of their fathers who died in hereſy; infamy, which excludes from all public offices, from bearing witneſs, making wills, &c. loſs of all dominion, natural or civil, as power of parents over children, maſters over ſervants, magiſtrates and princes over ſubjects, &c. and the deprivation of all property in every thing they have; impriſonment; bann, which is a kind of ſentence of excommunication, by which any perſon is caſt out of the commonwealth, ſo that he cannot enjoy the public protection, or diſcharge any public offices, or receive any benefit of law; diffidation, which declares heretics to be enemies of their own country and of the empire, ſo that any perſon, by his own private authority, may ſeize, plunder, and kill him, as an enemy and robber, even though he be a clergyman; nor is it lawful for any one to undertake their defence when apprehended; and thoſe advocates who favour and plead for them, are pronounced infamous, and ſuſpended from their office; and finally death, which is that of being burnt alive, in ſome caſes heightened by being gagged with an iron inſtrument, ſo that in the midſt of their torments they can utter only an inarticulate ſound.

It is the conſtant practice of the inquiſition to affect, in all their procedures, to inſpire as much terror and amazement as poſſible; every thing is done with the profoundeſt ſilence and ſecrecy, and with the greateſt rigour and pretended impartiality. When a perſon is ſeized, all the world abandons him; not the neareſt friend dares to ſpeak a word in his defence; that alone would be enough to render them ſuſpected of hereſy, and would bring them within the claws of the inquiſition; nay, the neareſt relations are bribed and conſtrained to accuſe one another. The criminals are ſeized, examined, tried, tortured, and, unleſs they recant, are even condemned and executed, without ever ſeeing or knowing their accuſers; whence the revengeful have a fair occaſion of wreaking their malice on their enemies. By the forms of the inquiſition, a perſon defamed only for hereſy is obliged to make a canonical purgation, *i. e.* to purge himſelf with ſeven, more or leſs, compurgators; ſo that if he fails in one, two, or three, he is accounted guilty: beſides, every one, though excluded by other courts, is admitted as a witneſs, a mortal enemy only excepted. The names of the witneſſes are not ſhewn to the priſoner; nor is any circumſtance diſcovered, by which he can obtain the knowledge of them. If two unexceptionable witneſſes teſtify of different facts; yea, ſometimes if there be only one, or a mere report, it is thought ſufficient for ordering the torture; the evidence of two unexceptionable witneſſes, who agree, is ſufficient for the conviction and condemnation of any perſon. Thoſe that are informed againſt are conſtrained to become their own accuſers; and various arts are uſed to extort a confeſſion from them. The advocate allowed them is under the direction of the inquiſition, and employed chiefly in order to betray them: moreover, when the crimes cannot be proved againſt them, they are only abſolved from proſecution, but their crimes and names are recorded againſt them. The uſe of torture for diſcovering ſecret crimes lying concealed in the mind, is a flagrant inſtance of injuſtice; and perſons are put to the torture upon half full proof of the crime, *i. e.* faultering, defamation, one witneſs of his own knowledge, or when the tokens are vehement, or violent. Theſe tortures are uſed under a pretence of diſcovering the truth, and they are varied and continued with the moſt wanton cruelty. After theſe, and many other ſhocking proceſſes, when the inquiſition has done with the criminals, and condemned them to death, they are turned over to the ſecular arm, with much prayer, and pious intreaty, that their lives may not be touched.

Time is no manner of ſecurity in point of hereſy; nor, does the grave itſelf ſhelter the accuſed from the purſuits of the inquiſition; even the deceaſed have their trials, and they proceed in all their form and ſolemnity againſt the dead carcaſes. The executions are always deferred till the number of the condemned is very great, that the multitude of ſufferers may ſtrike the deeper horror, and make the ſcene more terrible and ſhocking. See Act *of Faith*.

The inquiſition is very ſevere in the Indies. It is true, there muſt be the oaths of ſeven witneſſes to condemn a man; but the depoſition of ſlaves or children are taken. The perſon is tortured till he condemns himſelf; for his accuſers are never brought to confront him. Perſons are accuſed for the ſlendereſt expreſſion againſt the church; or even for a diſreſpectful word of the inquiſition.

The ſtandard of the inquiſition in Spain is a piece of red damaſk, on which is painted a croſs, with an olive-branch on one ſide, and a ſword on the other; with theſe words of the pſalm, *Exurge, Domine, & judica cauſam meam.*

The ſtandard of the inquiſition in Portugal hath their ſuppoſed founder Dominic's picture on one ſide, and on the other ſide the croſs, between an olive-tree and a ſword, with this motto, *Juſticia & miſericordia.*

See on the ſubject of this article Limborch's Hiſt. of the Inquiſition, by Chandler, paſſim. Moſheim's Eccl. Hiſt. vol. iii. p. 113, &c. 8vo.

INQUISITORS, in *Law*, are ſheriffs, coroners *ſuper viſum corporis*, or the like, who have authority to enquire into certain caſes, *ex officio*.

IN QUO, *Medium in quo*. See Medium.

INROLLMENT, the regiſtering, recording, or entering of any lawful act, or inſtrument, in the records of chancery; as a recognizance acknowledged, or a ſtatute, or a fine levied.

Inrollments are alſo made in the rolls of the exchequer, king's bench; and common pleas; in the huſtings at Guildhall, London; and by the clerk of the peace in any county. See Register.

Inrollments, *Clerk of the*. See Clerk.

INSAG, in *Ornithology*, a name given by the people of the Philippine iſlands to one of the ſeveral ſpecies of parrots, common in their woods. The inſag is a very beautiful bird; its body is of a very bright green, and its head of a fine florid red.

INSANITY. See Mental *Derangement*, Mania, and Melancholy.

INSANUM Parliamentum. See Parliamentum.

INSCHI, or Inschi *kna*, in the *Materia Medica*, a name given by ſome authors to the common ginger.

INSCONCED, in the *Military Art*, denotes that part of an army that have fortified themſelves with a *ſconce*, or ſmall fort, in order to defend ſome paſs, &c. See Sconce.

INSCRIBED, in *Geometry*. A figure is ſaid to be inſcribed in another, when all the angles of the figure inſcribed touch either the angles, ſides, or planes of the other.

Inscribed *Hyperbola*, is ſuch an one as lies entirely within the angle of its aſymptotes; as the conical hyperbola doth. See Hyperbola and Circumscribing.

INSCRIPTION, a title, or writing affixed to any thing, to give ſome farther knowledge thereof; or to tranſmit ſome important truth to poſterity.

Antiquaries are very curious in examining ancient inſcriptions found on ſtones, and other monuments of antiquity. Sanchoniathon, contemporary, as it is ſaid, with Gideon, drew moſt of the memoirs whereof his hiſtory is compoſed from inſcriptions which he found in temples, and on columns, both among the heathens and the Hebrews.

It appears, indeed, that the ancients engraved upon pillars the principles of ſciences, as well as the hiſtory of the world. Thoſe mentioned by Herodotus ſhew, that this was the firſt way of inſtructing people, and of tranſmitting hiſtories, and ſciences, to poſterity. This is confirmed by Plato in his Hippias, wherein he ſays, that Piſiſtratus engraved, on ſtone pillars, precepts uſeful for huſbandmen. Pliny aſſures us, that the firſt public monuments were made of plates of lead; and that the treaties of confederacy concluded between the Romans and the Jews were written upon plates of braſs; that, ſays he, the Jews might have ſomething to put them in mind of the peace and confederacy concluded with the Romans. The Greeks and Romans were much addicted to inſcriptions, and were extremely fond of being mentioned in them: and hence it is that we find ſo many in thoſe countries of ancient learning, that large volumes have been compoſed; as the collection of Gruter, &c.

Since Gruter's collection, Th. Reineſius has compiled another huge volume of inſcriptions. M. Fabretty publiſhed another volume at Rome in 1669, wherein he has corrected abundance of errors which had eſcaped Gruter, Reineſius, and other antiquaries, &c. and added a great number of inſcriptions omitted by them. Since all theſe, Grævius has publiſhed a complete collection of inſcriptions, in three volumes folio.

INSCRIPTION, *Academy of*. See ACADEMY.

INSCRIPTIONS, *Notes, or Abbreviations, uſed in.* See CHARACTER.

INSCRUTABLE, UNSEARCHABLE, in *Theology*, is uſually underſtood of the ſecrets of Providence, and the judgments of God, which cannot be found out, or into which human reaſon cannot penetrate.

INSE, in *Geography*, a town of Pruſſia; 22 miles W. of Tilſit.

INSECTS. See ENTOMOLOGY.

INSECTS, *Anatomy of.* Many parts of this ſubject have been already conſidered in the article ENTOMOLOGY, to which we refer the reader: our preſent object is to ſupply what has not been inſerted there.

Organs of Motion.—A ſtriking difference is obſerved in the poſition of the hard parts, which conſtitute the eſſential organs of motion, between this claſs and the mammalia, birds, &c. In the latter, the bones are placed in the centre of the limbs, and are ſurrounded by the muſcles, which are covered externally by the ſkin; while in the former, the reſiſting matters, which are analogous to bones and perform their functions, are hollow, placed externally, ſupply the place of ſkin, and contain the moving powers in their cavities.

The ſtructure and appearances of the external coverings vary conſiderably in the different orders of this claſs. In the crab, lobſter, &c. a hard calcareous cruſt covers the whole body and limbs, ſerving for ſkin and ſkeleton. In the perfect inſects the ſurface of the body is covered by horny ſubſtances of various degrees of hardneſs and reſiſtance. The larvæ have coverings of a ſofter kind, and approaching more nearly, as far as external characters go, to the ſkin of mammalia and of the neighbouring claſſes. Yet this is analogous in its functions to the calcareous and horny cruſts; for it receives the inſertion of the muſcles, and therefore conſtitutes the chief agent of locomotion.

The ſenſible characters of the calcareous cruſt of the crab and lobſter (their *ſhell* as it is commonly called) reſemble thoſe of the ſhells of teſtaceous animals, and in ſome degree thoſe of bone: but the chemical conſtitution is in ſome reſpects different. The very valuable reſearches of Mr. Hatchett have made us acquainted with the chief circumſtances of the compoſition of theſe matters. After having detailed his experiments on ſhells and on the coverings of the echini, he proceeds: "It was now requiſite to aſcertain if phoſphate of lime is a component part of the ſubſtance which covers the cruſtaceous marine or aquatic animals, ſuch as the crab, lobſter, prawn, and cray-fiſh. Pieces of this ſubſtance, taken from various parts of thoſe animals, were at different times immerſed in acetous and diluted nitric acid; thoſe which had been placed in the diluted nitric acid produced a moderate efferveſcence, and in a ſhort time were found to be ſoft and elaſtic, of a yellowiſh-white colour, and like a cartilage, which retained the original figure. The ſame effects were produced by acetous acid, but in a leſs degree; in the latter caſe alſo the colouring matter remained, and was ſoluble in alcohol. All the ſolutions, both acetous and nitric, afforded carbonate and phoſphate of lime, though the former in a larger proportion. There is reaſon to conclude, therefore, that phoſphate of lime, mingled with the carbonate, is a chemical characteriſtic, which diſtinguiſhes the cruſtaceous from the teſtaceous ſubſtances; and that the principal difference in the qualities of each, when complete, is cauſed by the proportion of the hardening ſubſtances, relative to the gluten, by which they are cemented; or by the abundance and conſiſtency of the gelatinous, membranaceous, or cartilaginous ſubſtance, in and on which the carbonate of lime, or the mixture of the carbonate and phoſphate, has been ſecreted and depoſited. And as the preſence of phoſphate of lime, mingled with carbonate, appears to be a chemical character of cruſtaceous marine animals, there is every reaſon to conclude that Linnæus did right not to place the echini among the teſtaceous ones. The preſence of phoſphate of lime, in the ſubſtance which covers the cruſtaceous marine animals, appears to denote an approximation to the nature of bone, which, not only by the experiments of Mr. Gahn, but by the united teſtimony of all chemiſts, has been proved principally to conſiſt, as far as the oſſifying ſubſtance is concerned, of phoſphate of lime." Philoſ. Tranſ. 1799. In a recapitulation of theſe reſearches, in the Tranſactions for 1800, he ſays, "it was proved, that the cruſt which covers certain marine animals, ſuch as crabs, lobſters, cray-fiſh, and prawns, conſiſts of a ſtrong cartilage, hardened by a mixture of carbonate and phoſphate of lime; and that thus theſe cruſtaceous bodies occupy a middle place between ſhell and bone, though they incline principally to the nature of ſhell." Similar reſults to theſe were obtained by Merat-Guillot, who has deſcribed his inveſtigation in the Annales de Chimie, t. 34. From 100 parts of lobſter cruſt, he obtained 60 of carbonate of lime, 14 of phoſphate, and 26 of animal matter. In 100 parts of cray-fiſh cruſt there were 60 of carbonate, 12 of phoſphate, and 26 of animal matter. So far as the horny coverings of inſects have been examined, they correſpond in chemical properties to horn, hoof, ſcales of ſerpents, feathers, &c. and do not owe their firmneſs to calcareous matter, which ſeems not to be an eſſential part in their formation. See HORN.

An intereſting enquiry ariſes here, concerning the mode of formation of theſe coverings; but our data are hardly ſufficient to reſolve it ſatisfactorily. "Some obſervations," ſays Cuvier, "ſeem to prove that there are teſtaceous animals, which loſe their ſhells entirely at certain periods, and are ſupplied with new ones. But this reproduction might be effected by developement like that of the antler: and if it be alſo a developement, which produces the interior layers of thoſe ſhells, which do not drop off, it may be compared to that which forms the inner lamina of the horns of cows, ſheep, and other ruminating mammalia, and alſo to the production of the epidermis in all animals: that is to ſay, it is a deſiccation, a kind of death of a membrane, which appeared to have ſome ſort of organization, as long as it was protected from the contact of the external air, or had not acquired completely its characteriſtic ſolidity. All the hard parts which hold the place of bones in invertebral animals ſeem to be developed in this manner. In the crab and lobſter, for example, that which ſerves at the ſame time for integuments and ſkeleton, grows no more when it has once attained its perfect hardneſs; yet the ſoft parts ſtill continue the progreſs of their developement. When they are too much confined by the hard covering, that ſeparates and is detached: but another is found under it, which was in a ſtate of formation while the former was detaching itſelf, or, as we may ſay, dying. This new covering is at firſt ſoft, ſenſible, and even vaſcular; but a quantity of calcareous matter, previouſly collected in the ſtomach, is very ſoon conveyed to it, hardens it, obſtructs the pores and veſſels, and renders it, in ſhort, perfectly ſimilar to that of which it has ſupplied the place. Inſects do not acquire their perfect hardneſs until they have taken their laſt form, and have no further change of ſkin to undergo; but all the ſkins which they had caſt off before, although ſofter, were dead, and already replaced by others, developed before they were diſcharged. Thus all the hard external organs of white-blooded animals, whatever their conſiſtence and chemical nature may be, ſhould rather be compared, in their mode of growth, to the epidermis, to hollow nails, and horns, than to true bones." Leçons d'Anatomie comparée, t. 1, p. 118.

Epidermis.—Cruſtacea and inſects, whether in their larva or perfect ſtate, have a true epidermis; but, as this integument, when it has once become dry and hard, is no longer ſuſceptible of that extenſion which is neceſſary to accommodate the growth of the animal, it is ſeparated at certain periods, which are definite in each ſpecies, but influenced conſiderably by the atmoſpherical temperature: the animal quits its ſkin, paſſing out from it as from a ſheath. This proceſs is called moulting: the inſect, in many caſes, is ſeveral days preparing for it, and ſometimes periſhes. Moſt of the larvæ of the papilio and bombyx kinds change their covering ſeven times before they paſs into the ſtate of chryſalis. The bombyx caja has ten ſucceſſive coverings.

This moſt ſingular proceſs is not analogous to the mere ſeparation of the cuticle in the human ſubject; for the parts which are detached in inſects, in many caſes afford attachment to the muſcles of the animal. Thus, in the cruſtacea the whole ſkeleton is ſhed, and this takes place annually. "Theſe frequent moultings," ſays Lyonet, "of the caterpillar of the phalæna coſſus are the more ſingular, inaſmuch as the caterpillar does not ſimply change its ſkin, but caſts its whole external covering, in which we obſerve the head, jaws, corneæ, all the ſcaly parts compoſing the lips, the cirri, the ſpinning hole, the antennæ, and even the ſcales encloſed within the head, and affording attachment to ſeveral muſcles; alſo the ſtigmata, the nails, ſcales, and hooks of the feet, the hairs, the anus, in ſhort all the viſible external ſurface of the animal. In diſpoſing itſelf for this operation, it paſſes ſome days without taking any nouriſhment; the muſcles, and other interior organs of the head, are detached from the old cranium, and withdrawn into the neck; they form a new covering, ſimilar to that which they have left, but larger, and at firſt ſoft. When the new ſkin, and all the other parts, which contribute to the covering of the caterpillar, are formed, the old one is opened, and the animal withdraws from it by an operation ſo much the more difficult in conſequence of the weakneſs cauſed by the ſoft ſtate of the new organs, which will not allow it to act with vigour, nor to take any nouriſhment for ſome days.

"The caterpillar, thus newly clothed, exhibits different proportions from thoſe which it had before moulting; the head, legs, and all the horny parts are ſenſibly larger in compariſon to the reſt of the body; theſe therefore do not increaſe afterwards. The body and ſoft parts of the animal only grow, until they become again too large for their covering, and a new moulting is neceſſary." Lyonet, Traité Anatomique de la Chenille, p. 7.

Rete Mucoſum.—The place of this organ is held in the cruſtacea, by the calcareous ſhell, which immediately ſucceeds the epidermis; its colour is commonly a dull green, ſometimes red, blue, white, or black. Alcohol, acids, and particularly the application of heat, often produce remarkable changes in theſe colours, as we may obſerve in the lobſters brought to our tables. In larvæ a layer of mucous ſubſtance is ſeen between the epidermis and the muſcles; and the colours of this vary infinitely in the different ſpecies. It is particularly remarkable for its brilliancy in caterpillars, and the larvæ of ſome hymenoptera; it gives to their bodies the pureſt and moſt lively tints, of which the ſhades and ſymmetry are admirable. Red, purple, violet, blue, green, yellow, ſcarlet, black, &c. are diſtributed in the moſt regular and ſtriking manner. Probably the brilliant colours of the perfect inſects are owing to the mucous body dried and blended with the horny covering. For whilſt the lepidoptera are in their chryſalis ſtate, the ſmall coloured ſcales which will afterwards adorn their wings, appear like the mucoſity which is under the ſkin of the caterpillars. The colours of the ſpiders are alſo owing to this mucous matter, which is found under their ſkin, and has the appearance of ſmall glandular points marked by different ſhades of colour. But in the coleoptera, and in ſeveral other orders, the colours ſeem to reſide in the horny tiſſue, as thoſe of the teſtacea do in their calcareous ſhells.

Nothing can be ſeen in this claſs, which can be compared to the cutis; there is a pellicle under the ſhell of the cruſtacea, but it is fine, tranſparent, and has very little conſiſtence. The layer which is ſeparated from larvæ in their moultings, is of the ſame nature and thickneſs as that which is under it and ſucceeds. The coverings of the contracted chryſaliſes, ſuch as thoſe of the lepidoptera and diptera, cannot be regarded as a true ſkin; it is rather a horny epidermis. Laſtly, in their perfect ſtate, inſects have nothing in their coverings which can be compared to cutis. The hairs of inſects ſeem to be productions of their epidermis; for they are diſcharged with that in moulting, and are ſupplied by new and longer ones. The ſcales of the wings and body in the lepidoptera and ſome other orders, are ſmall horny plates, differently coloured, implanted in the ſkin, and placed one over the other, like tiles in the roof of a building. The plumes of ſome inſects are prolongations or ſhreds of the wings, furniſhed with long hairs on their ſides.

Joints.—The cruſtacea and the proper inſects agree in the kind of their articulations; the particular nature of which ariſes from their hard parts being placed externally to the muſcles. The former being made like ſheaths, and having their cavities filled by the muſcles, cannot be articulated by ſimple and plane ſurfaces; their joints therefore exhibit no ſpecimens of arthrodia and enarthroſis. All their moveable articulations may be reduced to three kinds. Where the parts require a ſolid point of ſupport, the ginglymus is employed; the horny coverings of the limbs, being tubular, muſt reſt on each other in two points of their circumference at leaſt, and this arrangement neceſſarily determines the ginglymoid form. Where a ſolid point of ſupport is not required, the parts are merely ſuſpended by ligaments, or are articulated by a kind of ſetting in. In the latter conſtruction one part enters and is received into the hollow of another. Thus the thighs of inſects are ſet in the thorax, and the rings of the abdomen are ſet into each other. Since the part which receives, and that which is received, are ſegments of a ſpheroid, the latter may perform a twiſting motion: it may be puſhed more or leſs completely into the cavity, either equally in its whole circumference, or to a greater degree on one or the other ſide; but flexion properly ſo called cannot be performed. The parts which are connected by ginglymus, and which are chiefly the different portions of their legs, have deep notches on that ſide where the flexion is moſt extenſive; the interval is filled with a pliant membrane, and there is no other ligament. The articular tubercles and excavations are ſo arranged that they cannot be luxated without fracture.

Muſcles.—The muſcular ſyſtem of the cruſtacea is confined to the motions of the legs, tail, and falſe feet; there are no muſcles for moving the head on the thorax, ſince the two parts are conſolidated into one piece in this order. The antennæ, the jaws, and the palpi, have particular muſcles, but we ſhall not conſider them at preſent. The tail is a very principal part of the body in moſt cruſtacea. It conſiſts of a very ſtrong and moveable member, which they employ with great effect both in jumping and ſwimming. It is compoſed in ſeveral monoculi of long threads, which in the polyphemus (moluſca crab) are ſolid and moveable at their baſes only. In the crabs it is ſhort, flattened, and curved under the body in a depreſſion placed between the legs. The cancer bernhardus (hermit crab) has a ſoft tail without ſcales, which it introduces into empty ſhells or hollow ſtones.

The tail deſerves a particular deſcription in the lobſter, where it is formed of ſix chief ſegments, and terminated by five plates. The former are not all of exactly the ſame figure; they are convex above, and cover one another like tiles; below they are narrower, and united by a looſe membrane which allows them conſiderable mobility. In the latter ſituation, at the angle of union between their dorſal and lower portions, they have a kind of firm fins, bordered with ciliated proceſſes, and formed of ſeveral articulations. Theſe are called falſe or ſwimming legs (pedes natatorii). Theſe admit of being moved from before backwards, and a little from without inwards, by means of ſmall muſcles contained in their interior, but not differing ſufficiently from thoſe of the true legs to merit a particular deſcription.

The five plates, which terminate the tail, conſiſt of two pairs and a ſingle one; the latter is placed in the middle, and articulated directly to the laſt ſegment. The opening of the anus is found under it. In ſome ſpecies it is divided in its middle, ſo as to admit a ſlight motion. Each of the lateral pairs is ſupported by a common piece articulated to the laſt ſegment of the tail. The internal plate of each pair is ſimple, and ciliated, like the middle one, only at its extremity; but the external is in a manner articulated, or rather formed of two pieces; the firſt of theſe covers by its extremity, which is denticulated, the ſmaller which ſucceeds, and of which the edge is ſet with very cloſe cilia. The muſcles which move this tail are ſo ſingular, as to merit a diſtinct deſcription.

The muſcles of the tail, in the lobſter, form two maſſes, ſeparated from each other by the inteſtinal canal. In the dorſal maſs, which is the thinneſt, and leaſt complicated, three kinds of fibres may be obſerved. The firſt conſtitute a muſcle attached to the dorſal portion of the thorax towards its poſterior fourth part. It is then directed obliquely backwards and outwards towards the ſides of the firſt ſegment of the tail, in which it is inſerted. The portion of one ſide acting ſeparately, will carry the tail towards the right or left; when both act together, they will extend the tail, and maintain it in the extended ſtate. The ſecond and third ſeries of muſcular fibres are extended through the whole length of the tail in two parallel and contiguous lines. They ariſe from the upper and lateral portions of that ſeptum of the thorax, on which the branchiæ are applied, by ſeveral digitations. When it has arrived at the firſt ring of the tail, a ſmall interſection is obſerved on the ſurface, and we obſerve that a ſmall bundle of fibres turns off to be inſerted into this firſt annular ſegment; and a ſimilar inſertion takes place in each of the ſucceeding rings. This diſpoſition gives to the internal band the appearance of a twiſted cord. The external portion of the dorſal maſs is formed of diſtinct longitudinal fibres. Theſe three orders of muſcles have much analogy to the ſtraight dorſal muſcles of caterpillars, as we ſhall ſee in the ſequel.

The ventral maſs of the muſcles of the tail is much thicker and more complicated than thoſe of the back. In order to give a clear notion of its compoſition, we ſhall deſcribe it as obſerved in three aſpects. In the firſt place, from the back; the muſcles which we have deſcribed, as well as the inteſtinal canal, having been removed; ſecondly, from below, the ſcales which cover the under ſurface of the tail, and the nerves having been taken away; and thirdly, on the inſide, a longitudinal ſection having been carried through the muſcle in its middle line, in order to expoſe the internal ſtructure.

The ventral muſcle of the tail, on its dorſal aſpect, ariſes in the interior of the thorax, above the intricate bony texture, containing the muſcles of the legs. It is then divided into a right and left portion; each of which is formed of three broad digitations. Over the firſt ſegment of the abdomen, its longitudinal fibres dip under others, which turn round and embrace them. The reſt of the muſcle, in the whole length of the tail, is thus formed of two ſeries of convex fibres curved in parallel directions, placed laterally with regard to each other, and ſeparated from right to left by a channel in which the inteſtinal canal is lodged.

On the under ſurface three very diſtinct orders of fibres may be ſeen. The firſt is produced from the inferior ſurface of the digitations which ariſe from the bony frame-work of the thorax. The ſecond conſiſts of oblique fibres, which are a continuation of the former, extending from the middle line, in which the nervous cord is placed, to the ſides of the rings at the angle of union between their dorſal and ventral portions. Each of theſe angles, from the firſt to the ſixth, has two ſtrong bundles. The third ſeries is made up of tranſverſe bundles deſcribing arcs, of which the convexity is downwards. Theſe muſcular flattened hoops correſpond to the interſections of the rings, and ſeem to form derivative pullies for the oblique fibres juſt mentioned.

Laſtly, the ventral muſcle of the tail, divided longitudinally in its middle, reſembles a rope with the ſtrands rather obliquely diſpoſed. The fibres belonging to the tranſverſe bundles are diſtinct and narrower.

From this ſingular complication it reſults, that the muſcle, when inſulated from all its adheſions, conſtitutes a very cloſe twiſt, the threads of which, inſtead of acting in the longitudinal direction, move obliquely in the canal which they occupy between the neighbouring fibres.

The legs of the cruſtacea vary in number and ſize. Their figures are very different in the monoculi; ſometimes they hold the place of palpi, jaws, fins, branchiæ, &c. They differ conſiderably in form in the crabs, particularly the firſt pair. We ſhall deſcribe the legs of the crab and lobſter as an example of theſe organs. They are uſually five in number on each ſide, and each has ſix articulations. The firſt pair is conſiderably the largeſt, and forms what we call the claws.

The hip, or haunch, is attached to the cheſt, and moves only from before backwards. It ſupports one diviſion of the branchiæ, as well as the ſecond piece of the member, which correſponds to the thigh. The latter is flattened, ſhort, nearly ſquare, ſmooth, and a little curved. The plane of its articulation is parallel to the length of the piece; and as the two muſcles which move it are inſerted into the two moſt remote points, the thigh is ſituated horizontally. It has a hinge-like motion on the hip, combined of the two directions from before backwards and from within outwards. Its motion on the leg, which is very limited, takes place only from below upwards, and produces the approximation of the limb to the cheſt. The third portion correſponding to the leg is alſo rather flattened, particularly at its femoral extremity. It is ſlightly curved in the direction of the thigh, ſo as to correſpond to the convexity of the thorax. Towards the tarſal end it becomes larger and rougher: its motion on the thigh is very limited. The fourth articulation is intermediate between the pincer and the leg, on which it moves in a very diſtinct angle. The pincer compoſes the fifth, and by far the largeſt piece. It is terminated on the outſide by a pointed and ſerrated projection; and it receives on the oppoſite ſide a moveable pointed piece or pollex, capable of being oppoſed to it, which, with the other, conſtitutes the pincer. The motion of this on the fourth piece is from without inwards. The two following pairs of legs reſemble the former on a ſmaller ſcale, with this difference, that the two pieces, compoſing the pincer, are of equal ſize. The two laſt pairs of legs differ from the three others in not being terminated by a pincer, but by a ſingle nail. In every other reſpect they reſemble the two preceding pairs.

Muſcles of the Legs.—Each articulation has an extenſor and a flexor muſcle. The extenſor of the hip is ſituated in the interior of the thorax, on the horny piece which ſupports the branchiæ, rather in front of the hip, which it draws forwards. The flexor ariſes from the ſame part farther back, and produces the contrary motion to the preceding.

The extenſor of the thigh is ſtronger than the flexor; it is attached to the inner and front part of the hip, and to the ſuperior eminence of the thigh. It depreſſes rather than bends. The flexor, or rather the elevator of the thigh, is ſhorter than the former: it occupies the poſterior internal ſurface of the thigh, and is inſerted into the inferior eminence.

The extenſor of the leg is placed in the hollow of the thigh, of which it occupies the whole breadth; it is inſerted into the external border of the leg. The flexor is leſs powerful, lies under the extenſor, and is fixed to the inner edge.

The extenſor of the firſt piece of the tarſus is attached to the whole upper edge of the leg, and is inſerted into the higheſt eminence of the fourth piece. Its flexor ariſes from the lower edge of the leg, and is inſerted into the lower eminence.

The extenſor and flexor of the pincer occupy and divide the interior of the fourth piece: their functions are determined by their ſituation. The extenſor of the moveable piece or pollex is a very ſmall muſcle, occupying the upper part of the pincer: its flexor occupies all the reſt of this part, is a very bulky muſcle, and has a flattened oblong bony tendon in its middle. From this muſcle ariſes the great power of the animal in ſeizing and holding objects.

Organs of Motion in the Larvæ of Inſects.—As inſects undergo conſiderable changes of form at certain epochs of their life, they exhibit remarkable differences in their organs of motion. Hence it becomes neceſſary to deſcribe them in their various ſtates. All the winged inſects, which undergo a complete metamorphoſis, differ very conſiderably in their firſt ſtate from that which they have in the ſequel; and the moſt ſtriking of theſe differences regard the moving powers. At this time they are called larvæ or caterpillars; and they preſerve this form for a longer or ſhorter time after quitting the egg. They are covered with a flaccid and ſoft ſkin, divided into ſegments or rings ſuſceptible of motion on each other, by means of ſmall muſcular bands ſituated in the interior of the body. Frequently their motions are performed ſimply by crawling on theſe rings, after the manner of reptiles; or, by reſting ſucceſſively each of the ſegments of the body on the plane which ſupports it. Such is the caſe with the larvæ of the diptera, and of moſt of the hymenoptera. Sometimes the ſurface of theſe rings is furniſhed with ſpines, ſtiff briſtles or hooks, in order to give them a firmer hold on bodies: this may be obſerved in ſome flies, œſtri, tipulæ, &c.

On the under ſurface of the body in ſome orders, there are ſix feet near the head, each of which is formed of three articulations: the laſt is horny and terminated in a hook. By oppoſing theſe to each other the inſect can hold any object, hook itſelf to it, and then draw the reſt of the body towards this fixed point. This formation is ſeen in the coleoptera, and many of the neuroptera. The ſix feet are very ſhort, and hardly ſuſceptible of any uſeful application in ſome other coleoptera, *viz.* ſuch as live in the interior of wood, as the cerambices, rhagia (Fab.), &c. The latter move in the hollows which they excavate by means of their jaws, by which they attach themſelves, and with the aſſiſtance of plates or tubercles, with which their ſkin is furniſhed on the back and belly: their mode of proceeding may be compared to that of ſweepers in chimnies.

Laſtly, the lepidoptera, and ſome hymenoptera have, beſides the ſix horny articulated feet, a variable number of falſe feet, not articulated, terminated by hooks diſpoſed in circles and half circles, and attached to the ſkin on retractile appendices or tubercles: they move by fixing themſelves to bodies by means of theſe organs.

The larvæ of ſuch inſects as undergo an incomplete metamorphoſis, as the hemiptera, and of ſuch as paſs through none at all, as the aptera, except the flea, do not differ from the perfect inſect in the feet.

After this general ſtatement of the external organs of motions in the larvæ, we ſhall particularly deſcribe the muſcles of ſome. We ſhall firſt mention thoſe of the proper caterpillars; then thoſe of a ſcarabæus, which lives under ground; of a hydrophilus, which inhabits the water; and of a cerambyx, which is found in the hollows of wood.

1. *Muſcles of Caterpillars.*—The deepeſt ſtratum of muſcles in the caterpillar is formed of four principal rows; two correſponding to the back, and two to the belly: their direction is longitudinal. Those of the back are ſeparated from each

other by the longitudinal veſſel, and from thoſe of the belly by the tracheæ. They begin at the union of the firſt and ſecond rings, by two faſciculi ſlightly ſeparated from each other, which are inſerted into a kind of tendinous line produced by the union of the ſecond with the third ring. The ſame ſtructure exiſts in the ſubſequent rings. On the third, the fibres of the two faſciculi, although ſtill diſtinct, are much more conſiderable: on the fourth the internal faſciculus alone has its fibres ſeparate. The muſcle is continued, without any apparent interſection, over all the other rings. It diminiſhes in thickneſs towards the oppoſite end of the body, and forms again ſeveral faſciculi; at firſt three, then four, and, laſtly, five or ſix. The body is ſhortened when theſe muſcles act in conjunction with thoſe of the belly: it is curved upwards when they act alone.

The longitudinal muſcles of the belly are ſeparated from each other by the medullary cord, and from thoſe of the back by the tracheæ. Their direction is preciſely the ſame with that of the dorſal muſcle. They commence at the union of the two firſt rings by ſeveral faſciculi, which are united into one maſs over the third ring. Their fibres are ſeparated again behind, higher or lower according to the ſpecies, and form four or five muſcular cords, which terminate towards the laſt pair of falſe feet. Theſe aſſiſt the dorſal muſcles in ſhortening the body when both ſets contract together; but they antagoniſe them, when they act ſeparately, for they then incurvate the body downwards.

Between the long muſcles of the back and the ſkin ſhorter ones are found, having an oblique direction. Some are extended from without inwards, towards the dorſal line, between the annular interſections. Others occupy the ſame interval, but have an oppoſite direction, paſſing from within outwards, ſo as to deſcribe with the former the figure of the letter V. Theſe two orders of oblique muſcles have not every where the ſame quantity of fibres. In the firſt rings they are narrow and long: thoſe of the fourth, fifth, and ſixth are much ſhorter: further back they become much longer and more numerous in ſome ſpecies, while in others they ſtill continue broad and ſhort. Theſe muſcles act ſeparately on each ring, which they ſhorten by their ſimultaneous contractions; but, as they do not extend over the whole length of the ring, the parts correſponding to the folds, over which the oblique muſcles do not paſs, are elongated, when, by the action of the latter, the diameter of the ring is diminiſhed: thus progreſſion is facilitated.

Under the long muſcles of the belly is found another ſtratum, of which the fibres are oblique. Theſe very much reſemble the oblique muſcles of the back; and may be diſtinguiſhed, according to their directions, into two orders. Thoſe of one ſet are found nearer to the middle ventral line, in which the knotted nervous cord is found; and aſcend from within outwards, in the intervals of the rings. The others are not ſo oblique, with the exception of the three ſuperior pairs. Theſe muſcles, therefore, form, with the preceding, an angle, ſimilar to this kind of *A*.

The oblique muſcles which run from within outwardly, or the moſt internal, have many fibres. They uſually conſiſt of three or four diſtinct faſciculi. Thoſe which extend from without inwardly, or the moſt external, have fewer fibres, and never more than two faſciculi.

The action of theſe muſcles appears to be ſimilar to that of the oblique muſcles of the back; but it is probable that they alſo extend immediately the ſkin of the feet on which they are ſituated.

Beſides the longitudinal and oblique muſcles of the back and the belly, caterpillars have ſome which are lateral; that is to ſay, muſcles ſituated below and above the ſtigmata or apertures, which ought to be deſcribed ſeparately. Theſe muſcles are of three kinds, the *ſtraight*, the *tranſverſe*, and the *oblique*.

The ſtraight lateral muſcles are ſituated between the annular ſegments, above the ſtigmata. They are all placed longitudinally one over the other. Their points of attachment are covered by the tranſverſe muſcles. They ſeem intended to bend the body towards the ſides when they act ſeparately; but when they contract, in concert with the long muſcles of the back and abdomen, they ſhorten the body, and thereby aſſiſt its progreſſion.

The tranſverſe lateral muſcles are of two kinds: ſome, which are longer than the others, ariſe from the intervals unoccupied by the attachments of the ſtraight lateral muſcles, and are inſerted at the termination of the oblique external muſcles of the abdomen. Their fibres are diſpoſed ſomewhat in the form of a fan. The others have the faſciculi formed of parallel fibres; they are ſhorter, and are extended in each of the rings between the ſtraight, lateral, and oblique muſcles of the abdomen. Theſe muſcles diminiſh the diameter of each ring, and conſequently lengthen it in each of its folds. This mode of action is neceſſary for progreſſion.

The oblique lateral muſcles are ſituated on each ſide of the ſtraight. They proceed in an oblique direction from below upward, under the inſertion of the ſtraight lateral muſcles, which they aſſiſt when they act together.

Such are the muſcles of the body in general; but the true and falſe feet, and the head, have particular muſcles, which muſt be deſcribed ſeparately.

The muſcles of the true or ſcaly feet are ſituated within the three articulations of which theſe feet are formed. They may be diſtinguiſhed into thoſe which move the articulations, and thoſe which act on the *unguis*, or claw, that terminates them.

The muſcles of the firſt joint conſiſt of five or ſix faſciculi, which ariſe from the ſuperior margin of this articulation, and are inſerted into the ſuperior margin of the next. The muſcles of the ſecond joint are nearly equal in number, and are inſerted into the ſuperior margin of the third.

The muſcles of the unguis terminate by two tendons: but they are formed of ſeveral faſciculi, ſome of which ariſe from the ſecond and third joints in two very diſtinct layers; others from a line which correſponds with the convexity of the unguis; and laſtly, others from the line which anſwers to its concavity. Theſe tendons are inſerted into two tubercles at the ſuperior extremity of the unguis, on the concave ſide, towards its point. They ſerve to bend the unguis, which probably recovers its poſition by the elaſticity of its articulation.

There are two muſcles to each of the membranous or falſe feet. Their direction, with reſpect to the body, is almoſt tranſverſe. They extend from the centre of the feet, into which they are inſerted towards the back, and beyond the ſtigmata, whence they ariſe by lateral bands more or leſs oblique. Their uſe is to draw the centre of the foot inwardly, and to retract the hooks with which the limb is armed. It is probable that the contractions of the oblique muſcles of the abdomen produce the oppoſite effect.

With reſpect to the muſcles of the head, we ſhall at preſent deſcribe only thoſe which produce its entire motion. We ſhall notice the others in treating of the different functions to which they are ſubſervient. The muſcles which act on the head, bend it upward, downward, and towards the ſides. Thoſe which bend it upward are very numerous. They ariſe from the ſecond and firſt ring, and are inſerted into different points of the occiput; ſome near the middle line, others more laterally. They form, in general, two faſciculi. The moſt internal is the leaſt bulky. The lateral flexors are very oblique. They ariſe from the inferior or abdominal part of the body, and extend to the lateral parts of the occiput. The inferior flexors, which bend it downward, appear to be the continuation of the ſtraight muſcles of the belly. They conſiſt of eight or nine faſciculi.

2. *Muſcles of the Larva of a Scarabæus.*—The larvæ of the ſcarabæus have the body arched, and convex ſuperiorly, and concave on the ſide next the feet. The back and the belly are ſeparated by a membranous border, which has folds, and is ſituated under the ſtigmata. Theſe larvæ have only ſix articulated feet, none of which are membranous. On opening theſe larvæ longitudinally, either on the back or the belly, we obſerve three layers of deep-ſeated muſcles—the lateral, the dorſal, and the ventral.

The dorſal layer is formed of two tolerably diſtinct ſeries of fibres. One ſeries is external, and occupies the intervals of the ten firſt rings; that is to ſay, thoſe which are furniſhed with the ſtigmata. The muſcles which compoſe this ſeries are narrow, and preſerve a longitudinal direction. The ſecond ſeries is produced by fibres, which are ſomewhat oblique, and extended in the ſame ſpace, but more towards the middle line. Theſe muſcles are broader and ſtronger towards the head, and more narrow and leſs fibrous towards the tail. They terminate between the tenth and eleventh ring by a very narrow fleſhy band. Theſe muſcles ſeem intended to ſhorten the dorſal portion of each of the rings: this action diminiſhes the convexity of that part, and thereby ſerves to aſſiſt progreſſion.

Near the middle line, between the ninth and tenth ring, there are two ſmall muſcles a little oblique; but between the twelfth and the laſt ring we obſerve only one ſeries of ſmall ſhort muſcles, which occupy all the convexity deſcribed by the curvature. The action of theſe muſcles is obviouſly the ſame as that of the preceding, to which they are acceſſories.

When the firſt layer of dorſal muſcles is removed, we find fibres preciſely ſimilar underneath, but running in the oppoſite direction. Finally we obſerve, in the dorſal layer, lines of very ſhort muſcular fibres above the inferior plane of the ninth and tenth ring. The uſe of theſe little muſcles is probably the ſame as that of all the preceding, though their action is leſs apparent.

The ventral layer very much reſembles that of the back. Theſe muſcles, like the dorſal, form planes of oppoſite directions; the moſt deep-ſeated proceeding from the internal ſide, while thoſe which are neareſt the ſkin aſcend from the external ſide. This produces a ſmall but very regular rhomboidal figure in the middle of each ring on the line biſecting the belly. The action of theſe muſcles is the oppoſite of that of the dorſal layer.

On the laſt ſegment, and towards the part that anſwers to the anus, we obſerve a bundle of tranſverſe fibres, which, by their contraction, doubtleſs ſerve the purpoſe of a ſphincter.

The lateral layer of muſcles is compoſed of three kinds of fibres, which are very diſtinct with reſpect to their courſe. They repreſent a lace paſſed through the meſhes of a net. All theſe muſcles are ſituated behind the ſtigmata, and inſerted into the folds which ſeparate the belly from the back on both ſides.

Thoſe of the firſt order are completely tranſverſe. They extend over the union of each ring with the ſucceeding in the ſpace included between the ventral and dorſal muſcles. It is obvious that they muſt diminiſh, by their contractions, the diameter of the body, and conſequently extend it longitudinally. Theſe muſcles are in general very narrow.

The ſecond ſet is formed by oblique fibres which aſcend from without inwardly towards the middle ventral line, from the union of one inferior ring to the union of the preceding. Theſe muſcles are broad and very ſtrong, they ſerve to form the folds of ſeparation between the back and the belly.

The muſcles of the third order are leſs oblique than the preceding, to which they appear to be acceſſories. Each of the muſcles which compoſe this diviſion ariſes from the middle of a ring, and is inſerted under the head, where the preceding muſcles are inſerted, that is to ſay, on the ventral ſide.

It ſhould be remarked, that the two laſt rings have no lateral muſcles.

The muſcles of the head are very ſtrong, the flexors are attached to the ventral muſcles above the union of the ſecond ring with the third. They are formed of three principal faſciculi, which approach each other, and are inſerted into the poſterior and inferior part of the head, at the baſe of that ſcaly piece called, by Latreille, *ganache.* The extenſors or levators of the head conſiſt alſo of three faſciculi, but they are longer and ſtronger than the former. They have their origin in the ſide, and penetrate under the tranſverſe and oblique muſcles; one is attached to the ſixth ring; another to the fifth, and another to the fourth. They are inſerted into the poſterior lateral parts of the head.

3. *Muſcles of the Larva of a Hydrophilus.*—The larvæ of the hydrophili are elongated. Their body is ſomewhat flat, and all its rings are diſtinct. They not only walk very quick, but they even ſwim with great velocity, in conſequence of different inclinations ſuddenly and ſucceſſively given to the body.

Theſe larvæ, when opened longitudinally, likewiſe exhibit four different kinds or diviſions of muſcles: thoſe of the belly, thoſe of the back, and thoſe of both ſides.

The ventral muſcles very much reſemble thoſe of caterpillars: they are formed of two diſtinct layers. The deepeſt, or that which firſt appears on the belly when examined through an opening on the back, is compoſed of longitudinal fibres with interſections which correſpond to each ring; the ſecond layer, or that which is next the ſkin, is entirely covered by the preceding; it is compoſed of oblique fibres, which croſs each other in the form of an X, and which are extended longitudinally in each ring.

The dorſal muſcles are long, extending from the head to the tail, and forming on each ſide two rows of fibres, which appear twiſted over each other like ropes. They are broadeſt towards the head. Their fibres are inſerted partly into the inferior border of an anterior ring, and partly into the ſuperior border of the next ring.

Theſe long muſcles cover ſome which are oblique, and croſs each other in the form of an X. They extend from the middle part of one ring to the anterior edge of that which ſucceeds it.

The deep-ſeated lateral muſcles, which are numerous, have a tranſverſe direction. Each ring has three or four, and their courſe is ſuch, that they reſemble the letters N or M lying on one ſide, thus Σ Z.

Beneath the tranverſe lateral there are ſome longitudinal muſcles that have a ſmall degree of obliquity: they form a pretty large ſurface, which is uninterrupted throughout its whole length, and confounded with the oblique muſcles of the belly. Their fibres determine the chief motions of the body, in the ſame manner as the long muſcles of the back and belly.

The muſcles of the feet are the ſame as in the perfect inſect.

The head has no particular muſcles. The long muſcles of the back, being inſerted into the occiput, become extenſors. The firſt tranſverſe lateral pair are inſerted beneath the head, and produce the lateral flexion. The long oblique muſcles, which terminate at the inferior part of the head, become real flexors.

4. *Muſcles of the Larva of a Cerambyx.*—In the larvæ of the cerambices we find the ſame muſcles as in thoſe of the ſcarabæi; but as the ſhape of the body differs conſiderably in theſe two kinds of larvæ, there reſults ſome variation in the form and extent of the muſcular organs.

A great part of the head of the larva of the cerambices can be drawn within the ſkin whenever the animal pleaſes. Very ſtrong muſcles, ſimilar to thoſe we have deſcribed in the ſcarabæus, are appropriated to this function. As the head, which is very large, enters into the body, the extremity which receives it is ſomewhat thicker than the ſame part of the ſcarabæi, and the muſcles which move the rings are more extenſive than theirs.

The flat fleſhy tubercles which we find continued along the back and belly, are a kind of feet, which this larva uſes in progreſſion. They move by the alternate contractions of the correſpondent muſcles: this larva, therefore, moves with equal facility on the back and on the belly.

Of the Organs of Motion in Perfect Inſects.—The great variety of motions which inſects are capable of performing, entitles them to hold the firſt rank among the animals that have no vertebræ. We diſcover, in theſe minute beings, all the requiſites neceſſary to produce thoſe voluntary actions, the execution of which aſtoniſhes us in vertebral animals of far greater magnitude. They even unite ſeveral functions which are very ſeldom found combined in the other claſſes; for inſects walk, run, leap, ſwim, and fly with as much facility as the mammalia, birds, and fiſhes exerciſe one or more of theſe faculties.

Inſects are probably indebted for this advantage to the numerous articulations of which their bodies are formed. We muſt therefore pay attention to their different articulations, before we proceed to examine the actions they permit or produce.

1. *Of the Head.*—For a deſcription of the manner in which the head is articulated to the thorax, ſee Entomology, under the diviſion *Caput*, or *Head*.

The muſcles which move the head are ſituated within the thorax. We ſhall deſcribe here only thoſe moſt generally met with. The levators or extenſors of the head are commonly ſituated in the ſuperior part of the corſelet, and the depreſſors inferiorly.

Immediately beneath the middle dorſal part of the corſelet, we find a pair of muſcles which ariſe from the anterior portion of the ſcutellum, when that part exiſts; or from the ſuperior part of the pectus. Theſe muſcles are inſerted into the poſterior and ſuperior part of the head, on the edge of the occipital hole: they draw the head back, and lift it up when it is depreſſed.

On the lateral parts of this firſt pair we find another which is more ſlender: the inſertion of this pair likewiſe takes place at the occipital hole, but more outwardly. They ariſe obliquely from the lateral parts of the corſelet. Theſe muſcles turn the head to one ſide when they act ſeparately; they raiſe it, and bring the mouth into the middle line when they contract together. It will be eaſily conceived that inſects which have the head articulated like a knee, theſe rotatory muſcles are much ſtronger and more conſpicuous.

The flexors of the head are alſo four in number, two on each ſide. The firſt pair ariſes in the internal inferior part of the pectus, from a ſmall horny proceſs, which, in the coleoptera is of a ſquare form, and has the four angles terminated by ſolid branches. Theſe muſcles extend directly to the inferior part of the occipital hole. From their poſition they doubtleſs move the head directly backward. The ſecond pair, which are much ſhorter, ariſe from the inferior lateral part of the corſelet, and proceed to the ſide of the preceding, with which they concur in their effect when they act together; but when one of the two contracts ſeparately it bends the head to the ſide.

2. For the deſcription of the *thorax* or corſelet, of the *pectus* or breaſt, and of the *abdomen* or belly, ſee Entomology, under the reſpective diviſions.

3. *Of the Members.*—For an account of the number and ſtructure of the feet, ſee Entomology under the diviſion *Members*.

The motion of each joint is performed in a ſingle place. It is provided with two muſcles only, which are enveloped in the preceding joint. They are an extenſor and a flexor.

In the coleoptera the coxæ move by a kind of rotation on their longitudinal axis, which is ſituated tranſverſely, and forms, with the middle line of the body, an angle more or leſs approaching 90°. As the femur is attached to the internal extremity of the coxa, the diſtance between the thighs is greateſt in thoſe inſects in which the femur is moſt bent with reſpect to the coxa, to which it is articulated. It is obvious, therefore, that the poſition of the plane in which this flexion is made, depends upon the ſituation of the coxa; when it is turned forward, the plane is vertical; when turned backward the plane is always more oblique; and in the inſects that ſwim, it is even horizontal. It appears, then, that the almoſt imperceptible motion of the coxa determines the moſt remarkable movements of the feet.

The muſcles of each pair of coxæ and femora are ſituated in the ſuperior of the corſelet or of the pectus. To obtain a proper view of them, it is neceſſary to cut the body of the inſect in a vertical direction. Over the laſt pair in the pectus there is a ſcaly ſubſtance, in the form of a Y. The ſtalk of this part affords an origin to a muſcle which turns the coxa backward, and is inſerted into its poſterior edge. The muſcle which turns it forward ariſes from the back, and is inſerted by a thin tendon, into its anterior edge.

The muſcle which extends one femur, while it is approximated towards the other, is very conſiderable. It ariſes from the whole branch of the piece in the form of a Y, and is inſerted into the internal edge of the head of the femur. Its antagoniſt is ſituated within the body of the coxa.

The muſcles which extend the two pairs of anterior femora, ariſe from the correſponding dorſal parts, and not from particular internal ſubſtances: the flexors, however, are always ſituated within the body of the coxæ.

The muſcles which turn the coxæ ariſe alſo from the parietes of the corſelet; *viz.* the muſcle which moves it backward, from the dorſal part, and that which moves it forward, from the lateral part. In the water beetles, which, as we have obſerved, have the poſterior coxa conſolidated and immoveable, theſe muſcles ſeem to extend to the femur, which is therefore furniſhed with four, two extenſors and two flexors.

The other orders of inſects have nearly the ſame conformation as the coleoptera.

The muſcles of the tibia are ſituated within the femur. The extenſor, which is ſhort and ſlender, is attached to its external edge (the femur being ſuppoſed extended in the longitudinal direction of the body): the flexor is much ſtronger and longer. It is ſituated on the inner ſide, and in the whole of the ſuperior part.

There are likewiſe two muſcles to each joint of the tarſus: one, which is ſmall, and placed on the ſuperior or dorſal ſurface, acts as an extenſor. The other, which is more conſpicuous, and ſituated on the inferior ſide, acts as a flexor.

For the deſcription of the wings, ſee Entomology.

The muſcles that move the wings are not yet well aſcertained. They appear to be two kinds. Some, which are ſmall and ſhort, are fitted to extend or fold the wings, at the ſame time that they move them to or from the body: the others, which are ſomewhat longer, are calculated to produce the motions of elevation and depreſſion which the wings perform.

The elytra of the coleoptera, orthoptera, and hemiptera, do not appear to aſſiſt in the action of flying, at leaſt they are not moved in the ſame manner by the muſcles of the pectus.

Organs of Senſation.—On comparing together all the nervous ſyſtems, we find only one common part, which is a ſingle tubercle, ſituated at the anterior extremity of the ſyſtem, and always producing two lateral tranſverſe faſciculi or crura, which unite it to the reſt of the ſyſtem. This part appears always to correſpond to that named cerebellum in man. The cerebellum of animals that have red blood and vertebræ, is always preceded by ſeveral pairs of tubercles, forming uſually a larger maſs than the cerebellum itſelf, and united to the reſt of the ſyſtem by two longitudinal faſciculi or crura, which are interwoven in croſſing with thoſe of the cerebellum. This union takes place in ſuch a manner that both are confounded in the common maſs which forms the root of the medulla oblongata, and medulla ſpinalis, and leaves no ſpace between them. Theſe tubercles make what we call the cerebrum.

In the white-blooded animals, or thoſe that have no vertebræ, there are alſo tubercles correſponding to the cerebellum, but they are much ſmaller, removed from each other, and connected with the cerebellum only by ſeparate nervous filaments. The crura of the cerebellum leave a large interval between them, which receives the œſophagus as in a collar.

The two faſciculi, forming the medulla ſpinalis, are intimately united in vertebral animals, and no trace of their ſeparation remains, except a longitudinal furrow before and behind. But, in the animals which have no vertebræ, when this production exiſts, it is formed below the œſophagus by the union of the two crura of the cerebellum. Theſe two faſciculi commonly remain diſtinct throughout the greater part of their length, and are only united at different ſpaces by knots from which the nerves proceed. This production, however, frequently does not exiſt. In ſome animals with white blood, which have no elongation of the medullary ſubſtance, as in the molluſca, the nervous trunks, which are derived from the crura of the cerebellum, enlarge and form ganglia, or two or three nerves unite with each other to produce a common ganglion; and in general it is only from their ganglia that the nerves which are diſtributed throughout the body take their origin.

In thoſe white-blooded animals that have a knotted and double medullary production, that is to ſay, in the inſects, cruſtacea, and certain worms, the nerves all ariſe from the knots or ganglia of the medulla, or from ſome of the anterior ganglia of the cerebellum.

In the red-blooded animals the nerves of the ſpine ariſe from the medulla ſpinalis in two bundles of medullary filaments, which unite after the poſterior bundle has formed a ganglion. They afterwards ſeparate into two trunks, the anterior of which communicates with the great ſympathetic nerve by one or two filaments, and a ganglion is always formed at the place where they unite.

The great ſympathetic nerve, which is conſtantly found in all red-blooded animals, exiſts in none of thoſe with white blood; unleſs we ſhould regard as that nerve, the two nervous cords which unite all the ganglia, and which are commonly called medulla ſpinalis in the cruſtacea, inſects and worms. Were this opinion adopted, a medulla ſpinalis would be no longer attributed to thoſe animals, and the abſence of that production would then be the common character of all the white-blooded claſſes.

Inſtead of having the parts, which repreſent the brain and medulla ſpinalis encloſed in bony cavities, the lower orders of animals have them incloſed in the common cavities, with the other viſcera.

Brain and Nerves of the Cruſtacea.—The cruſtacea, which, in their organs of motion, very much reſemble the other inſects, though thoſe of circulation and reſpiration are exceedingly different, have alſo a ſimilar nervous ſyſtem, at leaſt in the eſſential parts.

In ſuch of the genus cancer as have long tails, the middle part of the ſyſtem is a knotted cord, which extends from one extremity of the body to the other. The ſhort-tailed kind, commonly called *crabs*, have a medullary circle in the middle of the abdomen, whence the nerves of the body proceed like radii.

In theſe animals the brain is placed at the anterior extremity of the ſnout, and conſequently at a conſiderable diſtance from the mouth, which opens under the corſelet. On this account the cords which make the collar of the œſophagus are more elongated than in other animals.

A. *Brain of the common Cray-Fiſh*, (*Aſtacus Fluviatilis*, Fab.)—The brain of this animal forms a maſs which is broader than long, and diſtinctly divided on the ſuperior ſurface into four round lobes. Each of the middle lobes produces an optic nerve from its fore part. This nerve proceeds directly into the moveable tubercle which ſuſtains the eye, and is there dilated and divided into a multitude of filaments, which form a pencil, and unite to all the ſmall tubercles of the eye.

Four other nerves ariſe from the inferior ſurface of the brain; theſe proceed to the four antennæ, and detach ſome filaments to the neighbouring parts. The cords which form the collar, ariſe from the poſterior part of the brain. About the middle of its length, each detaches a large nerve, which extends to the mandibles and their muſcles. Theſe cords unite under the ſtomach in an oblong ganglion, which furniſhes nerves to the different pairs of jaws. On leaving this part, the two cords remain near each other throughout the whole length of the corſelet, where they form five ſucceſſive ganglia, placed between the articulations of the five pairs of feet: each foot receives a nerve from its correſponding ganglion, which penetrates to the extremity of the foot: the nerve of the forceps is the largeſt. The medullary cords extend into the tail, where they are ſo intimately united that it is not poſſible to diſtinguiſh them. They form ſix ganglia, the five firſt of which produce each two pairs of nerves; the laſt produces four, which are diſtributed as radii to the ſcaly fins that terminate the tail.

The hermit crab, (*Pagurus*, Fabr. *Bernhardus*, Linn.)

the tail of which is not covered by articulated ſcales, appears to have much fewer ganglia than the cray-fiſh. We have obſerved only five.

In the *ſquilla*, Fabr. there are ten ganglia, without reckoning the brain: that at the union of the two cords which form the collar, tranſmits nerves to the two forceps, and to the three pair of feet which immediately ſucceed them, and which in theſe animals are ranged almoſt on the ſame tranſverſe line; this ganglion is therefore the longeſt of all. Each of the three following pairs has a particular ganglion. There are afterwards ſix ganglia in the length of the tail, which diſtribute their filaments to the thick muſcles of that part. The brain produces immediately four trunks on each ſide, *viz.* the optic, thoſe of the two antennæ, and the cord which forms the collar. As the antennæ are placed more poſteriorly than the brain, their nerves are directed backward.

B. *In the Common Crab* (*Cancer Mænas*, Linn.)—The brain of the crab reſembles that of the cray-fiſh in its form and ſituation: it alſo furniſhes analogous nerves, but they are directed more towards the ſides, in conſequence of the poſition of the eyes and the antennæ. The medullary cords which form the collar, detach each a nerve to the mandibles, but the cords are prolonged much farther backward than in the cray-fiſh before they unite. They join only in the middle of the thorax, at which place there is produced a medullary maſs of an oval ring-like figure, which is eight times the ſize of the brain. The nerves which proceed to the different parts ariſe from the circumference of this ring. It furniſhes ſix nerves on each ſide to the jaws and the five feet, and there is a ſingle nerve which ariſes from the poſterior part, and proceeds to the tail. This medullary ring may be ſaid to repreſent the uſual knotted cord, but if it has any ganglia they are not viſible.

C. *In the Oniſcus Aſellus.*—The two cords which compoſe the middle part of the nervous ſyſtem in this animal, do not perfectly join. We can diſtinguiſh them throughout the whole of their length. There are nine ganglia, excluſive of the brain; but the two firſt and the two laſt are ſo cloſe together, that the number may be reduced to ſeven.

D. *In Monoculi.*—We know not the nervous ſyſtem of the molucca crab (*limulus gigas*, Fab. *Monoculus polyphemus*, Linn.) In the monoculus apus of Linnæus, however, the indiſtinct nature of that ſyſtem, joined to ſome other peculiarities of organization, would almoſt induce us to claſs the animal with the inarticulated worms. The brain is a ſmall globule, nearly tranſparent, ſituated under the interval of the eyes. The medullary cord is double, and has an enlargement at each of the numerous articulations of the body; but the whole is ſo thin and tranſparent, that the real nature of the cord can ſcarcely be aſcertained.

Brain and Nerves of the Larvæ of Inſects.

A. *Coleoptera.*

1. *Larva of the Scarabæus Naſicornis.*—We ſhall give a particular deſcription of the nerves of this larva, becauſe their diſtribution is eſſentially different from that which takes place in the other coleoptera.

The brain is ſituated under the great ſcale which covers the head immediately above the origin of the œſophagus: it conſiſts of two approximated lobes, which are very diſtinct at the front and back part. Four nerves ariſe from the anterior part, two on each ſide, which are loſt in the cirri and parietes of the mouth.

From the lateral and ſomewhat poſterior parts of the brain, there ariſes a pair of nerves, which, embracing the œſophagus, proceeds inferiorly to form the nervous cord we ſhall preſently deſcribe.

Another pair departs from the inferior ſurface of the brain, or that part which reſts upon the œſophagus: theſe are firſt directed forward; they afterwards turn inward, and proceed above the middle and ſuperior part of the œſophagus, in order to approach each other. When they come in contact, they unite and form a ſmall ganglion, which produces a ſingle nerve; this nerve, continuing to proceed poſteriorly, paſſes below the brain, and accompanies the œſophagus to the ſtomach. It there enlarges again into a ganglion, which furniſhes ſome ſmall nerves that are ſent to the ſtomach, and one more conſiderable, which is continued along the inteſtinal canal, and ſends off, at regular diſtances, lateral filaments, which are loſt in the coats of this tube. This nerve is analogous to that which Lyonet has deſcribed under the name of *recurrent*, in the caterpillar of the *coſſus*.

The medulla ſpinalis, which, as we have ſhewn, is formed by the poſterior pair of nerves of the brain, is very thick at its origin: it forms a large fuſiform ganglion about 0,005 metre long, and half a millimeter broad. Four or five contractions appear on its anterior part, but they are ſo ſlight that they ſeem only tranſverſe furrows. The poſterior part of this ganglion is ſmooth.

From the lateral parts of this large ganglion, which extends very little beyond the third ring of the body, a great number of diverging nervous filaments are produced. Thoſe which are neareſt the head aſcend a little; thoſe which ſucceed them proceed almoſt tranſverſely; and the laſt are directed more and more poſteriorly: the length of each is in proportion to its diſtance from the anterior part of the ganglion. The two moſt poſterior filaments are therefore the longeſt.

2. *Larva of the Stag Beetle* (*Lucanus Cervus*).—The nerves of this larva differ greatly from thoſe of the preceding, although the perfect inſects are ſo nearly allied in genera.

The brain conſiſts of two contiguous and almoſt ſpherical lobes; theſe produce four nerves anteriorly for the antennæ and the parietes of the mouth: two inferiorly, which firſt proceed forward, then turn back, paſs again under the brain, and form a nerve known under the name of *recurrent*. Laſtly, two poſteriorly, which form a collar round the œſophagus, and join underneath, to compoſe the nervous cord of the body. This cord is formed of eight ganglia, which extend to the ninth ring of the body. The diſtances between theſe ganglia are very unequal; they are joined by very ſlender and cloſely approximated nervous filaments. The firſt ganglion, from the head, is very large, and almoſt ſpherical; it is followed almoſt immediately by the ſecond, which is one-half leſs, and which is diſtinguiſhed from it only by a kind of contraction; the firſt produces four pairs of nerves on each ſide; one aſcends to the head, the other three diverge and are loſt in the muſcles of the abdomen, and in thoſe that move the head. The ſecond ganglion, beſides the two nerves that unite it to the third, produces two other nerves, which are alſo directed backward, and loſt in the muſcles of the fourth ring. The third ganglion, and thoſe that follow as far as the eighth, are ſimilar to the ſecond; with this difference, that they are much more diſtant from each other, and that they produce longer filaments, in proportion as they are ſituated more inferiorly. Laſtly, the eighth and ninth ganglia are ſo cloſe together, that they ſeem to form but one, with a ſlight contraction in the middle. This double ganglion produces three pairs of nerves,

nerves, which are much elongated, and extend to the parts near the anus.

3. *Larvæ of the Cerambyx, Hydrophilus, Carabus, and Staphylinus.*—The nerves of theſe larvæ being very ſimilar, it will be ſufficient to deſcribe them in one genus only. We ſhall take for our example the larva of the great diver (*Hydrophilus piceus*).

The brain in this animal is ſituated in the head, above the origin of the œſophagus; it is formed of two lobes which lie very cloſe together. From its anterior part it detaches ſome filaments to the palpi, the antennæ, and the parietes of the mouth. Its lateral parts produce two cords which ſurround the œſophagus, and which are the origin of the nervous cord ſituated inferiorly. It is probable that recurrent nerves alſo ariſe from this inferior part, but we have not yet been able to diſcover them. The chief nervous cord is compoſed of ten ganglia, each of which produce three pairs of nerves that are loſt in the muſcles of the abdomen, and without any diſtinct appearance of their being diſtributed to the inteſtines. This induces us to believe that there is a recurrent nerve. The firſt ganglion is very large; it is prolonged poſteriorly into two nervous filaments, conſiderably removed from each other; the ſecond is almoſt ſimilar, but the third is very near the fourth, which produces only a ſingle filament poſteriorly. All the others, as far as the tenth, preſent no peculiarity. The laſt is divided by a ſenſible contraction; from the firſt portion a ſingle filament ariſes on each ſide, and from the ſecond, three pairs of nerves are detached: thus four pairs of nerves ariſe from this ganglion. The fourth pair is directed to the rudiments of the parts of generation, which are very diſtinct in theſe larvæ in the laſt period of their growth.

4. *Larva of the Water Beetle* (*Dytiſcus Marginalis*).—The brain of this larva is ſpherical, and conſiſts of a ſingle lobe, ſituated in the head above the origin of the œſophagus; its anterior part produces ſome filaments for the mouth; and its lateral parts the two optic nerves; the latter are compoſed of two parts which are very diſtinct as to form. The firſt portion, or that which is next the brain, is of an oval figure, pointed at the extremity which joins the brain: the other extremity is rounded, and produces a ſlender nerve, which goes directly to the eye. It is nearly of the ſame thickneſs throughout the whole of its extent; but it is enlarged at its free extremity into a bulb, from which the nervous filaments of the eye ariſe.

The two cords which embrace the œſophagus are ſhort and thick; they ariſe from the inferior ſurface of the brain, and immediately unite below the œſophagus, in a large ſquare-ſhaped ganglion, which produces anteriorly the nerves of the mandibles, and poſteriorly two cords, which paſs from the head into the corſelet. There is a greater diſtance between this firſt ganglion of the nervous medulla and the ſecond, than between any of the others. It is more than double that which exiſts between the two next ganglia. The ſecond ganglion is round; it produces two pair of nerves laterally; the anterior for the muſcles which act upon the head, the poſterior for thoſe which move the anterior feet. There are two cords poſteriorly, which are directed into the breaſt. The third ganglion is ſimilar in every reſpect to the ſecond; it furniſhes nerves to the intermediate pair of feet. The fourth ganglion is alſo produced by the two cords which come from the preceding; it is ſituated on the union of the abdomen with the breaſt; it is more broad than long. Laterally it produces two pair of nerves, which run tranſverſely parallel, and are loſt in the muſcles. The other eight ganglia are placed cloſe behind each other, and the ſpace between them is ſo ſmall, that we can ſcarcely perceive the two nervous filaments which unite them; they alſo decreaſe in thickneſs, without diminiſhing in breadth, as they extend poſteriorly. They all furniſh laterally a pair of very long nerves, which float in the abdomen, and for the moſt part terminate in the muſcles that move the wings. One pair, however, proceeds to the rudiments of the parts of generation.

B. *Orthoptera and Hemiptera.*—The nerves of the larvæ of orthoptera and hemiptera preſent no ſenſible difference from thoſe we obſerve in the perfect inſects. It will be ſufficient, therefore, to deſcribe the nerves of the latter.

C. *Hymenoptera.*—In the larva of the ſaw-fly (*Tenthredo*, Linn.), which has a large head furniſhed with eyes, the brain is very broad and ſhort; it ſeems to form four bulbs of equal magnitude, and nearly ſpherical; the two external ſerve as the baſe of the optic nerves, which are ſlender, and which enlarge a little at their other extremity. The firſt ganglion is produced by two very ſmall nerves, which ariſe from the inferior ſurface of the brain, and which, after having embraced the œſophagus, unite under the firſt ring of the body; it furniſhes filaments to the muſcles of the feet, and terminates poſteriorly in two other nerves, which, at the diſtance of one line, produce a ſecond ganglion, and ſo on in ſucceſſion; the nervous cord is in this manner formed of eleven ganglia, without reckoning the brain; the farther the ganglia are removed from the head, the more they diminiſh in thickneſs; they are all nearly of a round form.

D. *Neuroptera.*—In the larva of the lion-ant (*Myrmeleon formicarius*), the nervous ſyſtem has ſome relation to that of the larva of the dipterous inſects which we ſhall afterwards deſcribe.

There is a brain ſituated in the head; it produces nerves analogous to thoſe we have already pointed out in the other larvæ. The nervous medulla conſiſts, in the firſt place, of two ganglia, which are compoſed of two lobes, ſituated cloſe together; theſe two firſt ganglia are ſeparate from the others, and contained in the part correſponding to the feet, or in the thorax. The remainder of the nervous medulla is encloſed in the abdomen; it conſiſts of eight ganglia, placed in an exceedingly cloſe ſeries, and each formed of two lobes; the firſt is nearly double the ſize of the other ſeven. This ſucceſſion of ganglia appears to the eye like the extremity of the tail of a rattle-ſnake; the laſt is round; the others are more broad than long. All theſe ganglia furniſh nerves to the muſcles. It is probable that this diſpoſition and approximation of the ganglia have a relation to the changes which take place in the inſect at the moment of its metamorphoſis, as its abdomen then occupies ſix times the ſpace it does in the larva ſtate.

In thoſe larvæ of neuroptera, which are nearly as long as the perfect inſect, we find that the ganglia are ſeparated in the uſual manner.

The larva of the ephemera has eleven ganglia, without including the brain, which furniſhes two large optic nerves. There are three ganglia in the thorax, and ſeven in the abdomen: the firſt ſix, reckoning all the ganglia, furniſh more nerves than the five laſt.

The larvæ of the dragon-flies have a ſmall two-lobed brain, which produces optic nerves, larger or ſmaller according to the ſpecies. The genus aëſhna has them the largeſt. The reſt of the nervous ſyſtem forms a ſeries of ganglia of different ſizes. In the aëſhna, the corſelet contains ſix, the two laſt of which are the largeſt of all. There are ſeven ſmall and equal ganglia in the abdomen.

E. *Lepidoptera.*—The nervous ſyſtem of caterpillars conſiſts of a ſeries of thirteen principal ganglia, which furniſh filaments to all other parts of the body. The firſt of theſe thirteen ganglia is ſituated in the cavity of the head ; it lies above the œſophagus, and ſupplies the place of the brain : it appears formed ſuperiorly by the union of two round tubercles, inferiorly it is concave, and correſponds to the convexity of the œſophagus. This ganglion communicates with the reſt of the nervous cord by two thick filaments, which embrace the œſophagus, and which are united below it to the anterior and lateral part of the next ganglion ; it beſides produces eight pairs of nerves.

The firſt partly unites with other filaments ; produces ſome for the œſophagus, and forms ſeveral remarkable ganglia below the upper lip. The largeſt and moſt poſterior, which Lyonet has named the *firſt* frontal ganglion, is prolonged poſteriorly into a thick recurrent nerve, which is continued the whole length of the body, near the back ; this recurrent nerve furniſhes filaments to the œſophagus and its muſcles ; it penetrates into the dorſal veſſel, and it afterwards re-appears, and glides along the œſophagus as far as the ſtomach. This nerve produces, at certain diſtances, very ſolid filaments, which keep the œſophagus attached to the ſkin of the back.

Beſides the recurrent nerve we have juſt noticed, ſeveral filaments are furniſhed by the poſterior frontal ganglion to the muſcles of the œſophagus, and two to the *ſecond* frontal ganglion ; the latter alſo detaches ſeveral filaments to the œſophagus, and, in particular, a very remarkable one, which, by a ſudden englargement, conſtitutes the *third* frontal ganglion. This ganglion likewiſe affords ſeveral filaments to the œſophagus.

The ſecond pair of the brain appears chiefly intended for the antennæ, though it furniſhes ſeveral filaments to the neighbouring parts. The third pair terminates particularly in the antennæ, and the muſcles which move them. The fourth pair is proper to the eye of each ſide ; it accompanies the air-tube which goes to that part, and is divided into ſix branches, that penetrate into the ſix eyes, which, by their union, form that of the caterpillar. The fifth is directed a little backward, where it divides into two branches ; one poſterior for the adductor muſcles of the jaw ; the other anterior, which is loſt in the membranes that cover the frontal ſcales. The ſixth and ſeventh pair unite to form a ganglion from which ſeveral filaments are detached, to the œſophagus and its muſcles. Finally, the laſt pair of the brain is entirely loſt on an air-tube.

But beſides theſe nerves produced by the firſt nervous ganglion, ſeveral others are detached from it, which we ſhall briefly notice. In the firſt place, we obſerve, that it furniſhes ſeveral filaments to the dorſal canal : it afterwards gives origin to a pretty long filament, which terminates on the air-veſſels, between the ſecond and third ganglion. Laſtly, it produces a nervous ring, which embraces the œſophagus inferiorly like a girth, and ſupplies it with ſeveral filaments. The ſecond ganglion is intimately united with the third, and is diſtinguiſhed from it only by a contraction. The nerves which proceed from the anterior part appear to be produced by the ſecond ganglion, and thoſe which ariſe from the poſterior part, ſeem to belong to the third.

Beſides the two filaments which form the collar round the œſophagus, and which unite the firſt to the ſecond ganglion, the latter has four pair of very diſtinct nerves. The moſt anterior pair is ſent forward to the mouth, but in its courſe it divides into two branches : one terminates in the tongue and the adjacent parts ; the other branch proceeds to the lateral parts, where it ſub-divides, to ſupply the mandible, the jaw, and upper lip, communicating, at the ſame time, with the firſt ganglion, and with the ſecond frontal. The ſecond pair proceeds to the jaw, but detaches a number of filaments to the muſcles of the neighbouring parts. The third pair is deſtined for the ſpinning apparatus ; in its courſe it gives filaments to the ſilk-veſſels and muſcles of the head. The fourth pair ariſes near the contraction, which indicates the union of the two ganglia, between the head and the firſt ring ; it is loſt in the fat, in the ſkin of the neck, and in the muſcles inſerted into the head.

The third ganglion, which, as we have obſerved, is united to the ſecond, produces only three pairs of nerves : the poſterior is merely the continuation of the nervous trunk of the other two pairs ; the anterior is entirely loſt in the muſcles and the ſkin ; the intermediate pair ſupplies that part alſo ; but it is diſtributed chiefly to the muſcles, which move the articulations of the leg.

We have already ſtated, that each ganglion communicates with that which precedes, and that which follows it by two filaments that are diſtinct from their origin, and are the bifurcation of a ſingle trunk. The middle of this bifurcation, from the third to the eleventh ganglion, produces a ſmall nerve, which Lyonet has named the *ſpinal frænum :* this ſingle nerve is ſituated in the middle line ; it preſently divides into two branches, which follow the diviſions of the air-tubes, and penetrate with ſome of them into the longitudinal veſſel.

The fourth and fifth ganglia produce the ſame number of nerves, the diſtribution of which is alſo nearly ſimilar ; their anterior pair proceeds to the muſcles, and to the ſkin of the rings to which it correſponds ; the intermediate pair furniſhes, more particularly, filaments to the muſcles of the leg.

The ſixth ganglion, which correſponds to the fourth ring of the body, alſo furniſhes two pair of nerves, which are loſt in the muſcles and the ſkin.

The nerves of the five following ganglia are diſtributed nearly in the ſame manner.

The twelfth ganglion, and the thirteenth, which is the termination of the nervous cord, are very cloſe to each other, though diſtinct. The diſtribution of the nerves, produced by the firſt, preſents nothing remarkable. Thoſe furniſhed by the ſecond are very long, being ſent to the laſt rings, in the ſkin and muſcles of which the firſt pair is partly loſt. The ſecond pair is only ſubdivided when it has reached the firſt ring ; it there produces a plexus, from which a number of filaments are detached to the great inteſtine. The trunk appears to end on the parietes of the rectum towards the anus.

F. *Diptera.*—The nerves of the larva of the ſtratyomis have ſome reſemblance to thoſe of the larva of the ſcarabæus naſicornis.

The brain is formed of two lobes, placed cloſe together, and almoſt ſpherical ; it is ſituated above the œſophagus, on a level with the ſecond ring of the body. A number of ſmall nervous filaments ariſe from its anterior part, and are diſtributed to the parietes of the mouth, to the mandibles, and to all the adjacent parts. Theſe nerves are very diſtinct, particularly thoſe which are removed from the middle line. The poſterior part of theſe two lobes ſends off two thick branches which embrace the œſophagus, and form the origin of the nervous medulla. This nervous cord is very ſhort, and its diameter is one-half leſs than that of the brain ; it conſiſts of eleven ganglia placed very near each other, each of which produces one pair of nerves.

Theſe nerves proceed directly backward. Swammerdam has erroneouſly repreſented this cord as twiſted, like the tail of a ſcorpion, and producing nerves on the left ſide only. It is true, that thoſe which ariſe from the right ſide are parallel to the cord, while thoſe of the left ſide remove farther from it. The ganglia, thus approximated, are eleven in number, and in a ſtraight direction; they produce long nerves, which are loſt in the muſcles.

The nerves of the cheeſe-worm (*Muſca putris*, Linn.) are diſtributed in a very curious manner. The brain is ſituated immediately above the origin of the œſophagus, behind the head; it is very large in proportion to the reſt of the body; it is rounded poſteriorly, and notched anteriorly, as if it were formed of two lobes.

A pair of nerves ariſe from the anterior part of the brain, proceed forward, and are diſtributed to the mouth, and even to the parietes of that cavity. It ſhould be remarked, that theſe nerves experience a very conſpicuous enlargement previouſly to their diſtribution.

Poſteriorly the brain preſents an aperture, which affords a paſſage for the œſophagus: the nervous part, ſituated on its ſides, may be regarded as the cords which produce the medulla, and all below the œſophagus as the medulla itſelf.

Two pairs of nerves ariſe from the origin of the nervous medulla; theſe are directed forward, and principally diſtributed to the viſcera, and to ſome of the muſcles of the anterior rings. The third pair of nerves which this medulla produces is the moſt remarkable; it comes from the part which nearly correſponds to the third ganglion; we ſay nearly, becauſe in this inſect the ganglia are ſo cloſe to one another, that the medulla ſeems to form only one piece on the ſurface of which we merely perceive twelve tranſverſe wrinkles, which indicate the number of ganglia. This third pair extends almoſt tranſverſely. At a certain diſtance from its ſeparation it ſwells into a ganglion, and then divides into ſeveral filaments; theſe are the ganglia which Swammerdam ſuppoſes are intended for the muſcles of the wings, when they ſhall exiſt in the perfect inſect.

Another pair of nerves, which go to the muſcles of the body, ariſe from each of the other contractions; but they require no particular remark.

Brain and Nerves of Perfect Inſects.

A. *Coleoptera.*

1. *In the Stag-beetle* (*Lucanus Cervus*).—We find in this inſect, as in its larva, a brain compoſed of two approximated ſpherical lobes, ſituated above the œſophagus; its anterior part produces two pair of nerves, which terminate in the palpi and other parts of the mouth. There is probably a recurrent nerve, but our reſearches have not yet diſcovered it.

There are two ganglia on the lateral parts of the brain, which are almoſt as large as each of the lobes. In their form they reſemble a pear, and reſt upon the brain by their baſe; they are prolonged tranſverſely into a large nerve on each, chiefly intended for the eye. Before the nerve arrives at that part, we obſerve it detach a ſlender filament, which enters into the great mandible; then, more externally, another filament which enters into the cavity of the antennæ; laſtly, the nerve itſelf, having reached the eye, ſwells again into a bulb, and produces a number of nerves, which we ſhall deſcribe when we treat of the organ of viſion.

Poſteriorly the brain produces two very long and ſlender nerves which accompany the œſophagus to the point where the head unites to the thorax, immediately above the articular condyle. The two nerves ſituated above the œſophagus, then, produce a ganglion of a long oval form, from which ſeveral nervous filaments are detached to the muſcles that move the mandibles, and thoſe that act on the head. This ganglion terminates poſteriorly in two parallel nerves, which proceed to the middle of the thorax, above the origin of the two pair of feet, and there form a ſecond ganglion of an hexagonal figure; this ganglion furniſhes filaments to the muſcles of the feet, and likewiſe terminates poſteriorly in two nerves, which extend above the union of the corſelet, with the pectus; they there unite and form a third ganglion, which is creſcent-ſhaped, with the convexity poſterior: two other nerves proceed from this convexity, which almoſt immediately produce another ganglion of the ſame form, but ſmaller. This ganglion gives origin to five nerves: two lateral, deſtined to the muſcles of the intermediate feet, into the coxæ of which we obſerve them enter: poſteriorly two, which are ſlender, and diſtributed to the muſcles of the hind feet and the wings. The fifth is ſituated in the middle line; it is alſo thicker, it ſwells almoſt immediately into an oval-ſhaped ganglion, which is divided poſteriorly into two exceedingly ſlender filaments. Theſe filaments, which paſs into the abdomen, form a kind of bridge in the breaſt, in which they occupy the middle line, and leave between them the muſcles of the feet and wings of either ſide.

2. *In the Scarabæus Naſicornis.*—With reſpect to the nerves, this inſect differs in the perfect ſtate from the deſcription we have given of its larva. The optic nerves, which are very diſtinct and large, proceed to the eye, into which we obſerve them enter by a multitude of filaments when we make a horizontal ſection of that organ.

The nervous cord preſents a very conſpicuous difference. In the larva there is only a ſingle ganglion; but the perfect inſect has ſeveral, which are very diſtinct. The firſt is ſituated above the condyle; it proceeds from the two poſterior filaments of the brain, and is diſtributed to the muſcles which move the head on the corſelet. Its poſterior part produces two filaments, which paſs into the breaſt, where they unite towards the middle part, and form a triangular ganglion; from the ſides of which three pairs of nerves ariſe, and are diſtributed to the muſcles. Its poſterior angle detaches two parallel nerves, which proceed into the breaſt, where they form a third and a fourth ganglion, ſituated very near each other, and apparently divided into two lobes by a longitudinal furrow. All the other nerves of the body depart from thoſe two ganglia by an irradiation, preciſely in the ſame manner as in the larva.

3. *In the Water Beetles* (*Dytiſcus*) *and the Ground Beetles* (*Carabus*).—The nervous ſyſtem is entirely ſimilar in theſe inſects. The brain is formed of two large hemiſpheres, ſeparated from each other by a longitudinal furrow. The anterior part produces the nerves of the mouth, and the lateral parts thoſe of the eyes and antennæ. The nerves of the eyes are ſhort, and differ greatly from thoſe of the ſtag beetles; they are of a pyramidal form: their baſe correſponds to the eye, and their apex to the brain. We have not obſerved any recurrent nerves.

The two filaments which produce the nervous cord depart from the brain, not poſteriorly, but inferiorly, on the ſide of the optic nerves: they are very ſhort, as they paſs immediately under the œſophagus. They furniſh ſome filaments to the muſcles and the œſophagus. The firſt ganglion they form lies under a kind of bridge, formed of horny ſubſtance, which is ſituated in the middle of the head, and which affords a point of attachment to the muſcles of the jaws; it is of an elongated and quadrangular figure, and occupies almoſt the whole ſpace that correſponds to the condyle above which it is placed. It is terminated poſteriorly by two filaments which proceed in a parallel direction, and form a ſecond ganglion in the middle part of the corſelet. This ganglion furniſhes nerves to the muſcles of the anterior feet. We obſerve them enter into the cavity of the coxæ. The third ganglion appears bilobed, or formed of two oval bulbs, the union of which is marked by a longitudinal furrow. This ganglion is ſituated longitudinally above the anterior inferior edge of the breaſt. It ſends filaments to the muſcles of the intermediate feet. The fourth ganglion is very near the preceding; it is of a roundiſh form, and is diſtributed to the muſcles of the poſterior feet and the wings. The ſpace between the fifth and ſixth ganglion is very ſmall: their form is round; and they furniſh filaments to the muſcles that move the abdomen on the breaſt. The remainder of the medullary cord is formed by a ſeries of five ganglia, ſituated ſo cloſe to one another, that they appear to the naked eye to form only one; but with a glaſs they may be obſerved very diſtinctly. We even perceive the two filaments produced by each to form the ſucceeding ganglion. The fifth preſents a tranſverſe furrow, which ſeems to indicate the union of two ganglia. The end of the medulla appears to float in the abdominal cavity, but above the inteſtines.

4. *In the Great Diver* (*Hydrophilus Piceus*, Linn.)—The brain of this inſect, which is ſituated in the head, and above the origin of the œſophagus, conſiſts of two ſpherical bulbs cloſely united. The lateral parts give origin to the optic nerves which proceed towards the eyes without changing their diameter, but which terminate there by a triangular bulb that produces a vaſt number of filaments externally.

The anterior part of the brain detaches ſome filaments intended for the parietes of the mouth. We alſo remark, at the ſame place, a ſmall ſpherical ganglion, which appears to belong to the recurrent nerve that accompanies the œſophagus.

Two filaments, which ſhould produce the medullary cord, ariſe inferiorly: they embrace the œſophagus at their ſeparation, unite immediately below it, and again, in the cavity of the head, to form a ſmall ganglion, which furniſhes nerves for the muſcles of the mandibles and the palpi. Two nervous cords are detached from the poſterior part of this firſt ganglion. Almoſt immediately after their origin, they paſs under a horny arch, which is produced by the internal ſurface of the ganache. We obſerve that they re-appear poſteriorly, and proceed into the corſelet. They form a ſecond ganglion exactly in the middle of the corſelet; its figure is quadrangular. The anterior and poſterior angles produce the nerves of the medulla, and the lateral thoſe intended for the muſcles of the anterior feet. The interval included between the ſecond and third ganglion of the medulla is very great. The third ganglion correſponds to the inſertion of the intermediate feet: it is large, and of a round form; it furniſhes nerves to the wings, and to the intermediate pair of feet. Poſteriorly it produces two cords, which, at the diſtance of about half a line, ſwell and form a fourth ganglion, almoſt as large as the preceding. This ganglion detaches, from its inferior part, a number of filaments for the muſcles of the poſterior feet, which are ſpecially appropriated to ſwimming. Two other very ſhort cords produced by the poſterior part of this ganglion ſwell into a fifth, which is one-half leſs than the former, and which furniſhes a ſingle cord poſteriorly. This cord paſſes into a kind of longitudinal groove, formed above the horny appendix, that furniſhes attachments to the muſcles of the coxæ. A ſixth ganglion is ſituated at the poſterior and wide part of this appendix: at a certain diſtance, and exactly above the union of the abdomen with the breaſt, a ſeventh appears. Theſe two ganglia produce only one pair of nerves, which are diſtributed to the muſcles.

There are only two ganglia in the abdomen; one correſponds to the middle part of the ſecond ring; the other, which is the laſt and ninth, is ſituated above the union of the ſecond ſegment with the third. The laſt ganglion but one is in every reſpect ſimilar to the two preceding; but the ninth is one-half larger, and produces poſteriorly four pair of nerves, which are diſtributed on both ſides to the parts of generation.

B. *Orthoptera.—In the Cockroach* (*Blatta Americana.*)—The brain of this inſect is compoſed of two lobes, ſeparated by a very diſtinct notch anteriorly. The optic nerves ariſe on the ſides, and its anterior part detaches ſome filaments to the parietes of the mouth, and to the inſtruments of manducation.

The nervous cords which form the medulla ariſe from its inferior ſurface. They proceed directly downward, and cloſely embrace the œſophagus. They afterwards proceed in a parallel direction, but very diſtinct from each other, towards the corſelet. When they reach its middle, they form a very large ganglion, which produces three pairs of nerves laterally, and one poſteriorly. The firſt lateral nerves aſcend obliquely towards the head, and furniſh filaments to the muſcles that move it on the thorax, and which act on the antennæ and the parts of the mouth. The others are diſtributed to the muſcles of the firſt pair of feet.

The poſterior nerves proceed in a parallel direction backward. At the middle of the pectus they produce a ſtill more conſiderable ganglion than the ſecond, which furniſhes laterally nerves to the intermediate and poſterior feet, as well as to the muſcles of the wings. It alſo ſends off two cords poſteriorly, which, by their union at the junction of the abdomen and the breaſt, form a fourth ganglion, ſituated on a projecting horny ſubſtance to which the muſcles of the coxæ are attached.

After this fourth ganglion there is only a ſingle nerve, which has, at certain ſpaces, ſmall enlargements. Five of theſe ſwellings may be counted. Each produces a pair of nerves for the muſcles of the rings of the abdomen: the firſt is the largeſt, and furniſhes beſides two nerves which ramify in the parts near the anus.

In the Great Green Graſshopper (*Gryllus Viridiſſimus*, Linn.)—The brain is ſituated in the head above the œſophagus: it conſiſts of two lobes, which have the form of pears, united at their baſe, and prolonged at the other extremity into an optic nerve for the eye of each ſide. The anterior part alſo produces two nerves of a pyramidal form, the baſe of which reſts upon the brain. Some filaments ariſe from the apex of the pyramid, which are loſt in the mandible, the jaw and its galea, as well as in the upper lip.

Between theſe two anterior nerves we obſerve a ſmall ganglion, which is produced by the union of the two filaments of the inferior ſurface of the brain. This is the recurrent nerve which follows the inteſtinal canal. Poſteriorly, and a little inferiorly, we obſerve the origin of the two cords which form the nervous medulla. They embrace the œſophagus, below which they are immediately directed, and form a ganglion. This firſt ganglion is protected and covered by a kind of horny bridge of a reddiſh colour. It furniſhes nerves to the muſcles of the mouth, and to thoſe of the head within which it is incloſed. Poſteriorly it produces two long nervous cords, which penetrate into the corſelet. Theſe two cords unite about the middle of the thorax before the appendix, which gives attachment to the muſcles of the coxæ and the anterior pair of feet. At this union they form a large a large bilobed ganglion, of an irregular quadrangular figure, the ſides of which produce ſeveral filaments for the muſcles of the anterior feet.

The poſterior part of this ſecond ganglion furniſhes two filaments, which penetrate into the breaſt. The ſolid appendices of the coxæ, which afford inſertions for the muſcles, paſs between theſe two filaments. They form a third ganglion, which correſponds to the middle ſpace included between the two intermediate feet. This ganglion ſends nerves to the muſcles of the wings and the feet.

The fourth ganglion is alſo contained in the breaſt. It is ſituated before and between the poſterior pair of feet. It is produced by two nervous cords from the preceding ganglion; and furniſhes two poſteriorly, which are ſo cloſe to each other, that they appear to the naked eye to make only one cord. This nerve is received and contained in a kind of groove formed above the triangular piece, which affords an attachment for the muſcles of the feet.

The other ganglia, which are all ſituated in the abdomen, are ſix in number. They are, the laſt excepted, of the ſame ſize and form, placed at equal diſtances, and produced by two ſimilar and cloſely approximated cords. Each furniſhes two pair of nerves for the muſcles of the abdominal rings.

The laſt ganglion of the medulla is one-half larger than the five preceding. It is ſituated below the parts of generation, to which it is diſtributed by four pair of filaments.

In the Mole-cricket (*Acheta Gryllo-talpa.*)—The brain of this inſect is alſo compoſed of two rounded lobes, which are particularly diſtinct at the poſterior part. We can clearly perceive the origin of the nerves of the palpi, of the antennæ, of the ſmooth eyes, and of the eyes properly ſo called. In general the nerves of the principal medulla are ſimilar to thoſe we have deſcribed in the cock-roach. The two firſt ganglia are produced by two nerves. The firſt, which is in the corſelet, ſupplies the muſcles of the head, breaſt, and anterior feet. The ſecond, which is larger, and in the breaſt, gives filaments to the muſcles of the wings, and of the intermediate and poſterior feet. It alſo ſends two nerves poſteriorly, which produce the abdominal ganglion. The cord then becomes ſingle and flat, like a ribband, and contains only four ganglia, occurring at differeat diſtances. Each produces two pairs of nerves, which are directed poſteriorly, and diſtributed to the muſcles. The firſt correſponds to the middle part of the firſt abdominal ring; the ſecond to the third, the third to the fifth, and the laſt to the ninth.

This laſt ganglion is the moſt remarkable of all. It is of an oval ſhape, and produces, from the whole of its circumference, nerves which are diſtributed to the neighbouring parts. Two, which are longer than the others, diverge as they proceed backward, and thus repreſent a bifurcation of the medullary cord. Theſe branches furniſh filaments to the parts of generation.

C. *Hemiptera.—In the oval Water Scorpion* (*Nepa Cinerea*, Linn.)—The nervous ſyſtem of this inſect conſiſts of three ganglia. The firſt, which ſupplies the place of the brain, is ſituated in the head. It is formed of two approximated lobes. Theſe lobes are pyriform, and touch each other at their baſe. Their ſummits are directed obliquely forward towards the eyes, in which they terminate, and thus anſwer to the optic nerves by their anterior extremities. The middle and anterior part of theſe lobes alſo produce ſome filaments for the parts of the mouth. Poſteriorly, the brain detaches two cords, which embrace the œſophagus as they paſs below it. They unite at the origin of the breaſt in a tetragonal ganglion: each of the angles of which produces or receives ſeveral nerves. The anterior receives the two cords which come from the brain; the poſterior, the two which are the continuation of the medullary cord. Each lateral angle produces a faſciculus, compoſed of four nerves, which are directed to the muſcles of the breaſt and anterior feet. We obſerve one of them enter into the cavity of the coxa.

The two nerves produced by the poſterior angle of the ſecond ganglion proceed in a parallel direction backward. Having arrived in the breaſt above the horny appendix, to which the muſcles of the coxæ of the intermediate and poſterior feet are attached, they ſwell into a large round ganglion, conſiderably more voluminous than the brain. A vaſt number of nerves are detached from the edges of this ganglion, like ſolar rays. The two moſt remarkable filaments are exceedingly long and ſlender. They extend from the breaſt nearly as far as the anus: we have obſerved them to terminate by three minute branches in the parts of generation of the male, furniſhing, at the ſame time, ſome filaments to the adjacent parts. All the other filaments, which proceed from this third and laſt ganglion, are deſtined to the muſcles. We can very plainly diſtinguiſh thoſe that belong to the middle and intermediate feet, as they are ſomewhat larger than the others.

D. *Lepidoptera.—In the Zig-zag Moth* (*Phalæna Diſpar*, Linn.)—The brain in this ſpecies is almoſt ſpherical. We, however, perceive a longitudinal furrow on the middle line. Its anterior part produces ſome exceedingly ſlender nerves. There are two large optic nerves on the ſides, which proceed into the concavity of the eye, where they terminate by a bulb, which produces a great number of filaments.

The œſophagus paſſes immediately behind the brain, through a ſmall triangular interval, the poſterior ſides of which are formed by the two cords of the medulla. Theſe cords afterwards unite, and proceed in the form of a ſingle trunk, on the middle part of which we perceive only a longitudinal furrow. Arrived in the corſelet, it forms a ganglion, the ſurface of which is reddiſh. This ganglion produces two nerves poſteriorly, which leave between them an interval that affords a paſſage for the horny appendices to which the muſcles of the coxæ are attached. The two cords again unite behind theſe appendices in the ſame cavity of the breaſt, and produce a much larger ganglion, the lateral parts of which furniſh nerves to the muſcles of the wings and feet. It is prolonged poſteriorly into a ſingle cord, which again enlarges when it arrives above the articulation of the breaſt with the abdomen into a third ganglion.

It ſhould be remarked, that this large ganglion, which has the form of a heart, is the only one, beſides the brain, of a completely white colour. All the others exhibit darker ſhades, and we obſerve in them, when viewed by a glaſs, reddiſh points more or leſs elongated and ſinuous, that reſemble the blood-veſſels of injected glands.

The third ganglion is prolonged into a ſingle cord, which produces a fourth ganglion above the firſt ring of the abdomen. The latter, as well as thoſe that ſucceed it, detach on each ſide a long ſlender nerve which paſſes under the muſcular fibres, preciſely in the ſame manner as the threads of the woof paſs through the warp in cloth. Their direction is completely tranſverſe. The fifth ganglion does not differ from the preceding. It is prolonged into a ſingle cord, upon which we can ſtill very diſtinctly perceive the longitudinal furrow. It is ſituated in the middle part of the third ring of the abdomen. The ſixth ganglion is, in every reſpect, ſimilar to the preceding; it is placed in the middle of the fourth ring. Finally, the ſeventh and laſt ganglion is much larger than thoſe that precede it in the abdomen. It is of an oval form, and ſituated upon the lunula that terminates the fifth abdominal ring poſteriorly. Beſides the nerves intended for the muſcles of the fifth ring, which are detached from this ganglion in two diſtinct parts, it produces four other pairs poſteriorly. Theſe nerves appear to be diſtributed to the parts of generation, and to the muſcles of the laſt abdominal rings, which, in the female, are elongated like a tail to aſſiſt in laying eggs.

E. *Neuroptera.*—The inſects with naked wings, that is to ſay, the hymenoptera, neuroptera, and diptera, which have frequently very large eyes, have alſo the optic nerves of a proportional ſize. This is particularly obſervable in the dragon flies. Their brain is formed of two very ſmall lobes; but their optic nerves are dilated into the form of two large plates, which have the figure of a kidney, and which is ſpread upon all the inner ſurface of the eye next the head. The remainder of their medullary cord is exceedingly ſlender, and furniſhed with twelve or thirteen ſmall ganglia, the laſt of which is, as uſual, connected with the parts of generation.

F. *Hymenoptera.*—The brain of the bee is ſmall, and divided into four lobes. It produces immediately the nerves which are diſtributed to the different parts of the mouth, and the two large optic nerves which are dilated and applied behind each eye as in the dragon flies. There are afterwards ſeven ganglia, three of which are in the corſelet, and four in the abdomen. The nerves of the laſt chiefly ſupply the parts of generation.

G. *Diptera.*—The apiform fly (*Muſca tenax*, Linn.) has a ſmall brain, formed of two lobes, which are ſituated very cloſe together, but diſtinguiſhed by a longitudinal furrow; the anterior part produces a large nerve, which is afterwards diſtributed to the antennæ and the proboſcis.

The optic nerves are very thick, cylindrical, and equal in diameter to the length of the brain, on the lateral parts of which they reſt; they terminate at their extremities in very large bulbs, which correſpond to the breadth of the eyes.

The firſt ganglion of the medulla is produced by two cords, which come from the poſterior part of the brain, and embrace the œſophagus as a collar; it is very ſlender, and ſituated in the breaſt; it furniſhes a pair of filaments to the muſcles of the anterior feet.

The ſecond and the following ganglia, in all three in number, are united to each other merely by a ſingle cord. The laſt ganglion is one-half larger than that which precedes it. Poſteriorly it produces eight or nine filaments, which are intended for the parts near the anus; the firſt of the three is ſituated in the breaſt, where it furniſhes nerves for the muſcles of the wings and the feet; the other two ganglia are in the abdomen; the laſt but one is placed above the union of the third ring with the fourth; and the laſt on the interior and inferior edge of the fifth ring.

In the hornet-fly (*Aſilus crabroniformis*) we alſo obſerve a ſingle cord uniting the abdominal ganglia, which are ſix in number.

The brain is ſimilar to that of the ſyrphus; but the bulbs, formed by the optic nerves, are ſtill broader, in proportion to the extent of the eyes they have to inveſt.

H. *Gnathaptera.*—In the great ſcolopendra (*Scolopendra morſitans*) the brain has a very ſingular form: it is, as uſual, compoſed of two lobes, which are almoſt ſpherical; it produces laterally the optic nerves, which are very ſhort, and may be obſerved to divide long before they reach the eye. The filaments are four in number; but two nerves ariſe anteriorly, which are ſo very thick, that they appear a part of the brain, to which they are equal in diameter. Theſe nerves are particularly intended for the antennæ, into which we obſerve them enter, and in which they may be followed on account of their magnitude.

The two cords which embrace the œſophagus proceed directly downward, and form a large ganglion at the union of the firſt ring with the head. The firſt ganglion produces two nerves poſteriorly, and ſeveral towards the ſides. A ganglion, preciſely of the ſame ſhape, is placed above each of the articulations: thus there are, in all, twenty-four very diſtinct ganglia; the laſt of all is ſmalleſt, neareſt the preceding, and ſeems to float in the abdomen; each detaches three pairs of nerves; one which aſcends towards the head, a ſecond which runs tranſverſely; both theſe are diſtributed to the muſcles of the abdomen: the third deſcends, and then proceeds backwards and upwards; it furniſhes filaments to the lateral muſcles, and to thoſe of the back.

Organs of Senſe.—We have very little to obſerve on this ſubject, in addition to what will be found in the article ENTOMOLOGY, under the diviſions, *Organs of Taſte, Palpi, Olfactory Organs, Eyes, Stemmata, Organs of Hearing.*

Few ſubjects in comparative anatomy and phyſiology have given riſe to more various and contradictory opinions, than the organs of ſenſe in ſome claſſes of animals. Much miſunderſtanding on this point has clearly ariſen from the inconſiderate application to animals, of inferences drawn from the human ſubject. Thus, it has been ſuppoſed that thoſe which poſſeſs a tongue, muſt have it for the purpoſe of taſting; and that the ſenſe of ſmell muſt be wanting, where we are unable to aſcertain the exiſtence of a noſe. Obſervation and reflection will ſoon convince us, that the tongue, in many caſes (in the ant-eaters among mammalia, and almoſt univerſally in birds) cannot, from its ſubſtance and mechaniſm, be conſidered as an organ of taſte; but muſt be ſubſervient merely to the ingeſtion and deglutition of the food. Again, in ſeveral animals, particularly among inſects, an acute ſenſe of ſmell ſeems to exiſt, although no part can be pointed out in the head, which analogy would juſtify us in deſcribing as a noſe.

However univerſally animals may poſſeſs that feeling, which makes them ſenſible to the impreſſions of warmth and cold, very few poſſeſs, like the human ſubject, organs excluſively appropriated to the ſenſe of touch, and expreſsly conſtructed for the purpoſe of feeling, examining, and exploring the qualities of external objects. This ſenſe appears, according to the preſent ſtate of our knowledge, to exiſt only in three claſſes of the animal kingdom; *viz.* in moſt of the mammalia, in a few birds, and probably in inſects. All the obſervations and inveſtigations of the ſtructure of the antennæ, thoſe peculiar organs which exiſt univerſally in the more perfect inſects; and of the uſe which theſe animals generally apply them to; lead us inevitably to the concluſion, that they really are, what their German name implies (Fühlhorner; the literal tranſlation of which is feeling horns) proper organs of touch; by which the animal examines and explores ſurrounding objects. Such organs are particularly neceſſary to inſects, on account of the inſenſibility of their external coat, which is generally of a horny conſiſtence; and alſo from their eyes being deſtitute in moſt inſtances of the power of motion.

We are not warranted in conſidering the tongue as an organ of taſte in all animals, becauſe it is ſubſervient to that function in the human ſubject, and in ſome other inſtances. We have already obſerved, that this organ, in many caſes, ſerves merely for taking in the food; and it is at leaſt very doubtful whether it poſſeſſes the ſenſe of taſte in many others. Yet, on the contrary, we ſhould not be warranted in denying the exiſtence of the ſenſe in theſe animals, nor even in ſuch as are entirely deſtitute of a tongue; for this function may be exerciſed by other parts. The organ which is commonly conſidered as the tongue of inſects, merely ſerves for taking in the food. But the accurate obſervations of profeſſor Knoch, (in his Contributions to the Knowledge of Inſects, in German,) renders it very probable, that the poſterior pair of palpi, or feelers, poſſeſſes the power of taſte in ſeveral of this claſs.

Numerous facts have long ago proved, that ſeveral inſects can diſtinguiſh the odorous properties of bodies, even at conſiderable diſtances. But the organ in which this ſenſe reſides, has not hitherto been clearly pointed out. Since all red-blooded terreſtrial animals ſmell only through the medium of the air which they take in in inſpiration, ſeveral naturaliſts have ſuppoſed, that the ſtigmata of inſects are to be conſidered as organs of ſmelling. Others aſcribe this office, and with ſome probability, to the anterior pair of palpi.

There is no doubt that ſeveral inſects poſſeſs the ſenſe of hearing, but the organ of this ſenſe is very doubtful. In ſome of the larger animals of the genus cancer, a part can be diſtinguiſhed which ſeems to be analogous to the veſtibulum of the former claſſes. A ſmall bony tube is found on each ſide at the root of the palpi; its external opening is cloſed by a finer membrane; and it contains a membranous lining, on which a nerve, ariſing from a common branch with that of the antennæ, is expanded. The latter circumſtance might favour an opinion, that the antennæ themſelves are organs of hearing: but this is refuted by conſidering the exquiſite ſenſe of hearing, which ſome inſects poſſeſs, who have no true antennæ, as the ſpiders; and by experiments on others, which ſhew that the ſenſe of hearing is not weakened by removing the antennæ.

The compound eyes and the ſtemmata have been deſcribed in the article Entomology. The former are found in different numbers in moſt of the aptera, as alſo in the larvæ of many winged inſects. When theſe undergo the laſt or complete metamorphoſis, and receive their wings, they gain at the ſame time the large compound eyes. Several genera of winged inſects, and aptera (as the larger ſpecies of monoculi) have ſtemmata beſides their compound eyes. Farther inveſtigation is neceſſary to ſhew how theſe eyes enable the inſect to ſee; and to determine the diſtinctions between two ſuch very different organs. Blumenbach conſiders that the ſtemmata are deſigned for ſeeing near objects, and the polyedrous eyes for diſtant ones; becauſe butterflies have the latter only in their winged or perfect ſtate, while in the caterpillar ſtate they have only ſtemmata. He acknowledges, however, that this opinion is very doubtful, becauſe ſome inſects, which live completely underground, as the mole-cricket (gryllus gryllotalpa, Linn.) have both kinds of organs.

On the organs of the ſenſes in this claſs, the reader may conſult Lehmann, de ſenſibus externis animalium exſanguium: commentatio premio regis ornata, Goëtting. 1798, 4to. F. J. Schelver verſuch einer naturgeſchichte der ſinnes werkzeuge bey den Inſecten und Würmern; Eſſay towards the Natural Hiſtory of the Organs of Senſe in Inſects and Vermes; Goëtting. 1798, 8vo. Lehmann de antennis inſectorum, 1799, 8vo. Knoch's neue beyträge zu der Inſectenkunde; Contributions to the Knowledge of Inſects.

Organs of the digeſtive Functions.—For a general account of the parts about the mouth and their nomenclature, ſee Entomology.

Jaws of the Cruſtacea.—Moſt of the genus cancer have at their mouth five or ſix pairs of organs, which muſt be regarded as jaws, ſince they move laterally in a horizontal plane; they are placed ſucceſſively one over the other, and the moſt exterior has been called by ſome anatomiſts the lip, but wrongly; ſince it is not ſingle, and the two parts which compoſe it have lateral motion like the others. All theſe jaws are articulated under the thorax, anteriorly with reſpect to the feet, of which they ſeem to continue the ſeries in front; and each of them has, on the inner ſide of its root, a membranous plate, which, ſlipping under the lateral border of the thorax, between the anterior branchiæ, ſerves to ſeparate their lobes, and to compreſs them in the act of reſpiration, The feet have ſimilar laminæ for the poſterior branchiæ, but they are deficient in thoſe ſpecies which have the branchiæ under the tail, as the ſquilla. (Fab.)

Theſe jaws, with the exception perhaps of the one or two moſt interior parts, are formed of two diviſions; of one, which may properly be called the jaw, and another, which is its dorſal palpus or feeler. The latter is more elongated, and terminates in an articulated and pointed thread: the other has at its end, but in the two firſt pairs only, a feeler which does not end in a pointed briſtle like the other. This arrangement is common to the crab, lobſter, cray-fiſh, hermiteral, and, in general, to all the cruſtacea decapoda of Latreille. In the firſt the outer jaw is flattened, and joined ſo well to the correſponding piece and to its feeler, that the four pieces together form a kind of ſhield, which covers all the other jaws. But in the lobſter and cray-fiſh the outer jaw is priſmatic and ſtrong; and the diviſions of the feeler being nearly as large as the body of the jaw, the whole together reſembles a foot, and has often been deſcribed as ſuch by the ancient naturaliſts.

In the cruſtacea decapoda, the ſecond jaw, reckoning from the outer one, reſembles the firſt, whatever may be its form, except that it is ſmaller, and that its inner edge is extenuated and ciliated, inſtead of being denticulated. The body of the third is divided into two lobes, the fourth into four, and the fifth into two; all theſe three are thin and ciliated. The palpi of the two latter have generally a ſimple point inſtead of a thread. The ſixth is merely a ſmall, oval, membranous plate, without cilia or palpus. Some varieties are obſerved in the number and figure of the jaws in the cruſtacea. Thus, among the decapoda, the ſcyllarus (Fab.) has no thread-like proceſs on the dorſal piece of the two firſt jaws; the third is undivided, and the fourth only divided into two without a dorſal piece in either. The fifth and laſt is the uſual ſmall oval plate. Among the branchiopoda there are ſtill more remarkable differences: in the ſquilla (Fab.) the two firſt jaws are extremely ſlender and elongated, have the form of feet, and are terminated by a dilated rounded articulation, and a moveable hook. They really perform the office of feet, and not of jaws, and have no dorſal palpi. The third is a long plate, with three notches on its inner edge. The fourth is bifid; its inner lobe is ciliated; the external is pointed, and has on its dorſal ſurface a ſmall oval palpus of a ſingle articulation. The fifth and laſt is a ſimple plate.

Notwithſtanding all theſe varieties, it is ſtill true that all the cruſtacea have many pairs of jaws, very different from each other in their functions; and that theſe organs muſt act on the food, and prepare it for the proper maſtication in a peculiar manner. In fact, over all theſe organs are found the true mandibles, which are very ſtrong in all the genera. The triturating part varies in form. In the lobſter and cray-fiſh there is on the inſide a blunt and truly molar ſurface, and on the outſide a cutting edge divided into three rounded denticulations. In the hermit crab the denticulations are pointed and ſeparate. In the crab there is a continuous cutting edge. The ſcyllarus (Fab.) has two ſeparate denticulations; a pointed one in front, and a blunt one behind.

The ſtructure of the mandible is the moſt ſingular in the ſquilla. It is divided into two parts; an anterior one concealed under the lip, directed according to the axis of the body, pointed, and having two rows of ſmall denticulations; a poſterior tranſverſe one, with the cutting edge directed from below upwards, and poſſeſſing a row of ſtronger denticulations. All theſe mandibles have feelers: they are compoſed of three articulations, and dilated at the end in the lobſters, crabs, &c.; of three articulations, and pointed in the ſquilla; of a ſingle piece in the ſcyllarus, &c.

The entomoſtracea vary ſtill more than the ordinary cruſtacea. The molucca crab (monoculus polyphemus, Linn.), has five pairs of maxillæ, ſhort, compreſſed, and covered with ſmall ſpines; each poſſeſſing a very large palpus like a foot, with four articulations, terminated by a pincer like that of the fore-feet of the crab and lobſter. The pincers of the firſt pair are very large in the male. Thoſe of the laſt are ſmall, and accompanied by ſome ſcaly laminæ. In front of theſe maxillæ is the upper lip, of a priſmatic figure, having two palpi compoſed of two pieces, and terminated by pincers. The lower lip is behind the laſt pair of maxillæ, and is formed of two denticulated plates. The monoculus apus has two ſtrong and toothed mandibles, then two pairs of ſmall maxillæ without palpi, and laſtly twenty-ſix other pairs of broad plates reſembling maxillæ by their baſes, and branchiæ in the reſt of their extent, and of which the firſt has four palpi reſembling articulated briſtles: three of theſe are very long, and have been taken by ſome for antennæ. Theſe twenty-ſix pairs of plates occupy nearly the whole under ſurface of the body.

The ſmaller entomoſtracea have been very little examined in reſpect to the organs of the mouth. The family of the oniſci reſembles the cruſtacea in the multiplicity of their jaws, as by their four antennæ; perhaps it ought even to be entirely aſſociated to them. The firſt pair, which has alſo been called the lower lip, although it is clearly divided into two halves, is plane, and covers all the others: it has a very ſmall feeler on its external angle. Next to this come two or three thin oblong pairs, of which the ſecond is denticulated at its end: theſe have no palpi. The mandible is ſtrong, denticulated, and has a ſmall conical feeler. Theſe organs are exceedingly diminiſhed in the paraſitic ſpecies, as in the cymothoæ (Fab.), which have only two pairs of maxillæ, like ſmall ſcales, ſmall, conical, obtuſe mandibles without teeth, and in the middle of the whole a ſmall conical tongue. The pycnogonum ceti (Fab.) has no viſible jaws, although we can ſtill diſcern two articulated palpi. The proper place of theſe, as well as of the other pycnogona, cannot at preſent be aſſigned. But ſome paraſitic inſects, which have been arranged among the entomoſtracea, do not belong to that claſs, and have a ſucker, like fleas. Such are the numerous calygi (Cuvier) found on the gills of fiſhes, &c.

Muſcles of the Jaws.—The mandible is moved on the cheſt by two muſcles. One ſtrong and long approximates its looſe edge to that of the oppoſite ſide, and at the ſame time elevates it. It is fixed by two diſtinct fleſhy portions to the membrane which covers the thorax interiorly above and on the ſides of the ſtomach. One of theſe pieces is anterior and ſmaller: it is compoſed of ſhort radiated fibres, terminating in a ſlender bony tendon, articulated to the tendon of the firſt portion, of which it appears to be an angular production. The largeſt portion is leſs oblique; it is ſituated between the liver and ſtomach: its fibres, more numerous and alſo radiated, terminate at the extremity and front edge of the common bony tendon, which is itſelf fixed to the middle of the looſe edge of the mandible, which it tends to elevate by drawing it towards that of the oppoſite ſide.

The other muſcle is inſerted in a particular eminence near the middle of the oppoſite or fixed edge. Its fibres are ſhort and numerous. They paſs downwards and backwards, and are fixed towards the middle line of the bony caſe of the cheſt. Their contraction will produce a contrary effect to that of the preceding muſcle; that is to ſay, it will draw the edge of the mandible away from that of the oppoſite ſide.

There appear to be two other muſcles in the crab, having the ſame functions; but they are ſituated at the articulated extremity of the mandible. Each articulation of the feeler contains two muſcles, a flexor and an extenſor; of which the former is the largeſt. The flexor is placed in the broadeſt part of the concavity of the mandible: it is inſerted in a ſmall bony tendon ſituated at the anterior edge of the articulation. The extenſor is more ſlender, and attached to the fixed edge of the mandible; it is attached by a long and ſlender tendon to the poſterior edge of the articulation of the firſt piece. The muſcles of the two other pieces of the feeler are arranged nearly in the ſame manner.

The maxillæ are moved from within outwards, and reciprocally, by muſcles analogous to thoſe which we have juſt deſcribed as belonging to the mandibles; and the pieces which compoſe them, when they conſiſt of ſeveral articulations, contain in their interior two muſcles, an extenſor and a flexor, very ſimilar to thoſe of the legs.

Moreover, each of the maxillæ, and particularly of the lower ones, has, on the piece correſponding to the hip in the legs, one, two, and ſometimes three laminæ directed interiorly to the cavity of the branchiæ; theſe will be conſidered in the account of reſpiration.

Jaws of Inſects.—1ſt. *In the Gnathaptera* (Cuvier.)—This order obſerves no common law, like all thoſe which are founded on negative characters only; it muſt be divided into families, in order to obtain ſome general rules. The firſt, that of the millepedes, affords none; for the iuli have only ſmall mandibles, under which is a conical piece compoſed apparently of the lower lip and the maxillæ conſolidated together, without any feeler. The ſcolopendræ have ſmall mandibles, larger maxillæ without palpi, a pair of palpi under them, and a large lower lip, of which the articulated and pointed palpi form together a ſtrong pincer. The ſecond family, or the arachnidæ, has ſtrong mandibles which cannot cut, but are armed at their extremity with a moveable hook, often forming a pincer, with a prominence of the body perforated for ſucking. The maxillæ are ſcarcely viſible, and only ſerve to ſupport palpi, which are always very long, and in the form of feet, and ſometimes enormous, as in the ſcorpions, where they reſemble the claws of crabs. In the phrynes, where they furniſh the animal with a formidable weapon, there is neither lower lip nor labial palpi. We might conteſt the propriety of calling theſe organs mandibles, ſince they ſerve for ſucking and not for maſticating; but their poſition, and the analogy of other inſects, forbid us to refuſe them this name. Fabricius has founded the character of his claſs of unogata on the ſmall moveable hook which terminates them.

The third family, that of the ricini, or fleas of birds, has only mandibles, between which is a ſmall roſtrum, and appears to have neither maxillæ nor lips. Thoſe of the lepiſma and podura have not been ſufficiently examined.

2dly. *In the Neuroptera.*—This order is not much more conſtant than the preceding in the forms of the mouths of the inſects belonging to it. We meet firſt with the beautiful family of the agnatha, inſects deſtined to live ſcarcely a few inſtants in the perfect ſtate, and poſſeſſing merely what is neceſſary for copulation and laying. They have no occaſion

ſion for eating, and poſſeſs only an imperfect mouth, without any mandible, and with membranous maxillæ attached to the whole length of the lower lip.

The family of the odonata, or libellulæ, which are the moſt ſtrongly armed, and the moſt cruel of inſects, is of a nature quite oppoſite to theſe. Their mandibles have an anterior, hooked, and, as it were, cutting portion, and a poſterior truly molar ſurface, with four pointed tubercles. It is curious to obſerve in theſe inſectivorous inſects the ſame characters as in the quadrupeds which are nouriſhed by ſimilar food. The maxillæ are divided into long pointed denticulations like needles, and have palpi without articulations. An enormous lower lip covers all this apparatus; it is divided into three or four lobes, of which the lateral ones are themſelves ſometimes terminated in the form of pincers.

The other neuroptera are leſs diſtinctly characterized. They have, in general, ſtronger or weaker mandibles; maxillæ with articulated palpi, which are two in number for each maxilla in the myrmeleon and the aſcalaphus, and ſolitary in the others; a lower lip, terminated by a tongue, which is ſimple in moſt kinds, divided into four in the termes and pſocus, having two very large and club-ſhaped articulated palpi in the myrmeleon; and no particular characters in the other genera.

The moſt curious mouth, in this order of inſects, is that of the panorpa. Its mandibles are ſmall, and placed at the end of a long ſnout; of which the under part is filled by a lip, and very elongated maxillæ conſolidated together. Here the ſubdiviſion of the lip commences, into the horny piece (ganache of Latreille) at the baſis, which ſupports the labial palpi, and the tongue, or membranous organ, placed at the extremity between the labial palpi.

3dly. *In the Hymenoptera.*—This natural family, the moſt intereſting of the inſect tribe, by the numerous and varied inſtincts with which the different ſpecies are endowed, has, in the ſtructure of its mouth, a character of which the firſt appearance has juſt been indicated in the panorpa. Part of the baſis of the maxillæ, and the horny portion of the lower lip (the ganache), are there united by a membrane, and are always moved together. The portion of the jaw beyond the feeler covers the tongue more or leſs, and ſerves it for a ſheath, which is ſometimes very complete.

The hymenoptera, which ſuck the nectar of flowers, may be recognized by the prolongation of their maxillæ and lower lip, which are often much longer than the head, but admit of being folded up ſo as to be withdrawn under the production of the mandibles. This kind of organ is ſometimes placed on a pedicle, which admits of being moved backwards and forwards. This may be ſeen in the bee and the neighbouring genera. In theſe elongated trunks the tongue forms the eſſential part, the true ſucking tube: but it is always only rolled ſo as to form a half tube, and opens longitudinally below.

In the bee, one of the articulations of the labial palpi is prolonged, and forms the firſt ſheath of the tongue; the outer portion of the jaw is prolonged in a ſimilar way to form a ſecond ſheath; Fabricius calls this ſtructure lingua quinqueſida. In the Eucera (Fabr.) two ſcales of the baſis of the tongue, which are clearly ſeen in the bee, where they are very ſmall, are prolonged as much as the tongue, and the organ is therefore a lingua ſeptemſida. In other genera the labial palpi do not ſerve for ſheaths, and the trunk is therefore trifid, as in the ſphex arenaria, &c. Even where the tongue is not prolonged into a trunk, it is always opened below; and this is a character peculiar to the hymenoptera, whence it reſults that their mandibles aſſiſt them but little in procuring their food, but ſerve them merely as armour, and as inſtruments for working. What they might chew would arrive with difficulty at the under ſurface of the tongue to be ſwallowed; but the latter organ imbibes nutritious matter in the liquid form, or in a ſtate of minute diviſion, as the pollen of plants, &c. Theſe genera with ſhort tongues preſent very intereſting differences in the form of the organ. It is ſometimes ſimple and conical, as in the evania, or formed like an oval ſpoon, as in the ſirex, the mutilla, and the hornet, or dilated and grooved, as in the leucopſis, or divided into three pieces, as in the tenthredo, or into three conical and villous briſtles, as in the ſcolia, or more or leſs equally and deeply divided into three or four lobes, as in the veſpæ, and moſt of the genera ſeparated from that of ſphex, &c. Theſe different configurations determine the kind of food which the animal employs, and the ſituations in which it procures it. The differences of the maxilla are leſs important: it forms in front merely a ſcaly piece, covering the tongue above, and having its length proportioned to that of the tongue.

The palpi vary more in their abſolute and relative length, in the form and number of their articulations. The bee has exceedingly ſmall maxillary palpi. The ſame may be ſaid of the ſirex, but the labial palpi are here large and club-ſhaped. Moſt others have them filiform or ſetaceous, and with ſeveral joints. The upper lips ſometimes aſſumes a peculiar form for a particular office. In the leaf-cutting bees, for example, it forms a ſcaly ſhield, protecting the trunk, upon which it is folded back, that it may not be injured by the edge of the leaf which the mandibles cut.

4thly. *In the Coleoptera.*—Theſe, although they are exceſſively numerous, form a natural order. Their lower lip is not placed between the maxillæ, as in the preceding order, but really below, ſo as to conceal a part of them, when the mouth is obſerved from below; conſequently they are articulated between the lip and the mandibles, and not ſuſpended with the lip in a common membrane, as is the caſe in the hymenoptera. The opening of the pharynx is alſo formed upon the tongue, and not below it, as in the hymenoptera, ſo that the produce of maſtication takes that direction naturally. Such are the true characters of the mouth in this order; but that of having the maxilla free from adheſion to the lip is not excluſive, as Fabricius ſeems to have ſuppoſed, when he founded on this idea the name of eleutherata, which he has given to theſe inſects.

There ſeems to be only one family in this order, of which the character is determined in a ſtriking manner by the organization of its mouth; it is that of the carnivora. All of theſe have prominent mandibles and maxillæ, which are alſo hooked and cutting, four maxillary and two labial palpi; conſequently they are terrible enemies to other inſects. The chief circumſtance, by which they are diſtinguiſhed from each other, is the figure of the horny and membranous part of the tongue, which are more or leſs lobated: they may alſo differ in ſome unimportant acceſſory, as the ſpines of the maxillæ, &c.

Another family, as natural as the preceding in all the circumſtances of its external and internal organization, that of the lamellicornia, poſſeſſes ſcarcely any common characters in the parts of the mouth. Some have enormous projecting mandibles, more or leſs reſembling the horns of the ſtag (lucanus); others have only ſhort but ſtrong mandibles (the dung-beetles, geotrupes of Latreille); in others they are membranous and ſcarcely viſible (the cetoniæ, Fabr. the ſcarabæi, the copris.)

Some have ſtrong maxillæ well furniſhed with teeth (the
melolonthæ,

melolonthæ, Fabr.) ; others have them ſimply ciliated (the cetoniæ), or in the form of a pencil (the lucani.)

The ſame variations take place in the lips and palpi, and are not merely obſerved between the different genera. For, although great pains have been taken to ſubdivide this family into numerous genera, none of theſe arrangements are founded on a perfectly ſimilar conformation of the mouth. Nothing can prove more clearly the impracticability of the project, ſo reſolutely perſiſted in for thirty years by M. Fabricius, of eſtabliſhing a method of inſectology on the conformation of the mouth only.

A third natural family of the coleoptera, that of the roſtricornia, is characterized by having its mouth at the end of a long ſnout. Such of the others as are well determined, for example, the herbivora, the lignivora, &c. have no ſtriking character common to all the genera, although there is a certain reſemblance.

The different configurations of the palpi, of the horny and membranous portions of the tongue, of the maxillæ, &c. have been carefully deſcribed by naturaliſts : but their labours have not hitherto furniſhed any general remarks which ſuit our preſent purpoſe.

5thly. *In the Orthoptera.*—This order is very uniform in the ſtructure of the mouth ; it poſſeſſes always ſtrong mandibles and maxillæ, under which is the lower lip. A moveable upper lip covers the mandibles more or leſs completely. The maxillæ are ſtrongly denticulated, and have always an articulated feeler, and another not articulated, which ſometimes grows ſo broad as to cover and protect the maxillæ, whence it has been called galea : but often it is as ſlender as a thread. The lower lip has always two articulated palpi, between which is a more or leſs divided tongue. The pharynx opens upon the tongue, as in the coleoptera, not under, as in the hymenoptera ; ſo that theſe inſects are true maſticators : the principal differences of the genera are founded on the diviſion of the part called the tongue, and on the equality or inequality of the portions. Thus, in the mantis there are four, pointed and equal: in the phaſma the two middle ones are much the ſhorteſt. The achetæ, locuſtæ, and acridia of Fabricius, have the two outer ones broad and rounded ; and the intermediate one ſhort and pointed. The blattæ and the forficulæ have two oblong ones ; the truxalides (Fabr.) the grylli, and the pneumoræ, have only two rounded ones, &c.

6thly. *In the Larvæ of Inſects.*—Theſe organs are not diſtributed in the larvæ, as in the perfect inſects : many larvæ with jaws produce perfect inſects, which have none, ſuch are all thoſe of the papilios, and ſeveral of the diptera. Different larvæ have often ſimilar jaws when the inſects produced from them have very different ones ; as in the whole family of the lamellicornia.

The larvæ of inſects which go through an incomplete metamorphoſis, have the ſame kind of mouth as the perfect inſects, with the exception of ſome modifications in the proportions of parts ; thus the mouth of all the orthoptera is the ſame in the three ſtates. The change of proportions juſt mentioned produces the moſt ſenſible effects in the neuroptera odonata or the libellulæ. Their mandibles and maxillæ are the ſame in the larva as in the perfect ſtate. Their lower lip preſents alſo the ſame diviſions, but it is placed on a very long pedicle, with an angular turn or elbow in its middle, ſo that it remains commonly in its natural poſition under the maxillæ, but the animal can, by ſtraightening the curved pedicle, carry it ſuddenly conſiderably forwards : and, as the notches which terminate it will ſerve the purpoſe of pincers, they are employed for ſeizing the ſmall inſects which come within reach. When the libellula has its wings, it no longer needs ſuch an artifice : its lip is ſhortened, and confined to the ordinary functions.

The larvæ of the hymenoptera have very ſimple organs of maſtication, conſiſting principally of ſmall, ſhort, and ſtrong mandibles. The mouth of the larvæ of the coleoptera has the ſame parts as that of the inſects ; but they are differently ſhaped. Thus the lucani, which in the perfect ſtate have ſuch enormous mandibles, and ſuch peculiar pencil-ſhaped maxillæ, have, while larvæ, a nearly orbicular upper lip, immediately articulated with the front ; ſhort, ſtrong, thick, pointed mandibles, ſlightly arched externally and on the inner ſide ; towards their looſe extremities they have three denticulations on one plane, and towards their baſes a ſtriated and plane molar ſurface : it is plain that theſe are in their mouth inſtruments for cutting and chewing wood. The maxillæ are terminated by two ſmall hooks, of which one is moveable, a very ſingular ſtructure, and ſupport a feeler of four articulations. The lower lip is broad, and in a manner truncated, and has two palpi ; each compoſed of two pieces.

The ſcarabæi differ remarkably from the lucani in their mouth ; but the two genera agree almoſt entirely in the mouths of the larvæ ; the ſame obſervation may be made of the melolonthæ and cetoniæ, which are alſo very different from each other.

This ſmall moveable hook may be conſidered as a ſecond maxillary feeler ; theſe larvæ would then have ſix, while their perfect inſects have only four. We muſt obſerve alſo, that the larvæ, both of the lucani and of the ſcarabæi, have two ſtrong teeth on the upper ſurface of the lower lip near the pharynx.

The prioni (Fabr.) which have elongated mandibles like the lucani, have nothing of this kind in the larva ſtate. There is a very large upper lip, lobated, rounded, villous, ſupported by a membranous lamina, then two ſtrong, curved, cutting mandibles, furniſhed at their baſes with two conical palpi, of which the rings enter one into the other, like the tubes of a teleſcope, and which are probably the rudiments of antennæ. A ſoft maſs, conſiſting of three lobes placed behind the mandibles, repreſents, by its middle lobe, the lower lip with two very ſhort rudiments of labial palpi, and, by each of the lateral lobes, the maxillæ properly ſo called with its proper palpi, compoſed of four conical articulations, of which the laſt is the ſmalleſt.

On the contrary, the dytiſci, which have very ſlightly prominent mandibles, have them very long in the larva ſtate. They repreſent two ſharp hooks, perforated at the extremities, which ſerve for ſucking. There are no viſible maxillæ, but merely two long filiform palpi of five pieces ; while the perfect inſect has four maxillary palpi. This is exactly the reverſe of what we have juſt ſeen in the lamellicornia. Inſtead of the lower lip there are two tubercles, each of which ſupports a feeler of two pieces. The larva of the hydrophilus alſo wants the maxilla, but has four palpi ; the mandibles are ſhort, cutting, and not perforated.

Of all larvæ, thoſe of the lepidoptera differ the moſt widely from the perfect inſects in reſpect to the mouth ; and, what is very ſingular, their mouth is conſtructed on the plan of that in inſects with jaws, although it poſſeſſes no trace of theſe parts in the butterflies. Under a ſemi-orbicular upper lip, and under two ſtrong, cutting, denticulated maxillæ, are three tubercles repreſenting the lower lip and the maxillæ ; the latter ſeem compoſed of pieces, which enter more or leſs one into the other, and terminate by two ſmall tubercles, of which the internal, armed with two ſtiff briſtles or teeth, is the maxilla properly ſo called; the other is the feeler. The lower lip has two very ſmall palpi, and a hollow point in the middle: this is the ſpinning hole, through which the ſilk comes out, employed by the caterpillar for forming its coccoon.

The Muſcles.—When the upper lip is moveable, it is drawn backwards by two bundles of fleſhy fibres ſituated within the cranium, and which are themſelves divided into two planes. The motions of the mandibles are analogous to thoſe of the hips in inſects. At the baſis, on the ſide correſponding to their convexity, there is a kind of condyle, or convex rounded eminence, received into a ſmall cotyloid cavity, excavated in the temporal ſcale in front of, or below the eye. On the ſide correſponding to the cutting edge of the mandible, there is commonly obſerved, at leaſt in large inſects, ſuch as the ſcarabæus monoceros, the prionus, the capricorne (cerambyx), the lucanus cervus, the locuſta, a kind of ſolid tendinous plate, which is apparently prolonged into the interior of the ſolid parietes, and affords attachment to muſcular fibres implanted in it laterally, as the barbs of a feather are on the common ſhaft. Theſe muſcles approximate the jaws to each other, or ſhut the mouth. Thoſe which ſeparate the mandibles and open the mouth are much ſhorter, and not one-tenth of the ſize of the preceding. They are inſerted in a ſmall apophyſis, correſponding to the convex external line of the mandible, on the outſide of the condyle. Lyonet has deſcribed and figured theſe muſcles in the larva of the phalæna coſſus. He calls them adductors and abductors; but he has regarded as ſo many diſtinct organs, the faſciculi of fibres inſerted into the common tendon; ſo that he has diſtinguiſhed nearly eleven muſcles or bundles deſtined to cloſe the mouth, and three principal planes for the purpoſe of opening it. Theſe fibrous planes are found in all other inſects; but very great varieties are obſerved in their number and relative diſpoſition. Theſe differences depend evidently in the firſt place on the very different inſertions of the tendinous plates, which are to be conſidered as prolongations of the muſcles: they ſeem alſo to be modified by the length and ſize of theſe plates. The latter always have a relation to the form and extent which the internal parietes of the mandible and of the cranium afford for their inſertion.

Salivary Organs.—No expreſs organ, for the purpoſe of ſupplying a ſalivary ſecretion, has been hitherto diſcovered in the cruſtacea; but the place of ſalivary fluids is ſupplied in the following manner. The branchiæ, placed at the ſides of the body, under the edges of the corſelet, are compreſſed and agitated by the cartilaginous plates connected to the jaws and feet; at this time, the water in contact with the branchiæ flows along theſe plates, and comes out at the two ſides of the mouth; hence, when a crab or lobſter is taken out of the water, much froth is obſerved to iſſue from that part. This water, although foreign to the body, may ſerve to moiſten the food, when the animal eats out of water. At other times no ſaliva can be needed, as in the cetacea and fiſhes.

Many inſects furniſh, during maſtication, more or leſs fluid, which is often acrid, and of a penetrating odour, and ſupplies the place of ſaliva. In the carabi it is black and fœtid, very corroſive in ſome grylli; and capable, in the larva of the coſſus, of ſoftening and diſſolving the wood of the willow, on which the animal feeds.

The ſources of theſe fluids are not yet known in all ſpecies; probably, however, they are produced by organs analogous to each other, and thoſe of one ſpecies may ſerve as an example of the reſt. The larva of the coſſus has two long ſpongy veſſels, like all the ſecretory organs of inſects, very much convoluted, and opening into a large reſervoir, which communicates with the mouth by a ſmall canal. This organ ſeems to produce a liquor, neceſſary to the animal for the purpoſe of acting on the wood by which it is nouriſhed. It is deficient, or very ſmall in moſt other caterpillars.

Organs of Deglutition.—1ſt. In inſects with jaws. The membranous extremity of the lower lip, in the coleoptera, and the orthoptera, which has been called a tongue, ſcarcely deſerves that name. But in the ſecond of theſe families there is a real fleſhy tongue, looſe only at its point, and analogous in figure to that of quadrupeds. The odonata, among the neuroptera, have a ſtructure ſomewhat ſimilar; but the tongue of the hymenoptera is only a membranous tube, often open below, and forming the extremity of the lower lip. In the waſps, and in all the hymenoptera, which have no trunk, it has an arched form, being open and concave below, and more or leſs divided into pieces. The bees, and all the hymenoptera which have a long trunk, poſſeſs a complete tube with annular fibres: ſuction is performed by the ſucceſſive contraction of theſe fibres.

2dly. In inſects without jaws. Since deglutition is the firſt act of nutrition in theſe inſects, the form of the organ employed in ſuction determines the ſpecies of juice which the animal can imbibe, and conſequently influences very conſiderably its way of life. The relations of the natural families of theſe animals to their organs of ſuction, are much more conſtant than they are to the inſtruments of maſtication in the other half of the claſs. There are four orders of inſects without jaws, *viz.* hemiptera, lepidoptera, diptera, aptera; and there are three kinds of ſuction particularly belonging to the three firſt of theſe. The hemiptera have a ſtiff proboſcis enveloped in a ſheath; the lepidoptera a membranous trunk ſpirally convoluted; the diptera a trunk terminated by two fleſhy lips. Hence the names of rhyngota, gloſſata, and antliata applied by Fabricius to theſe three orders; which he has preſerved the ſame as in the Linnæan arrangement, and which many others had adopted before.

The greateſt varieties are obſerved in the diptera. In this order the organ conſiſts eſſentially of a fleſhy trunk, divided below into two lips more or leſs prolonged, and capable of being applied to the object which is to be ſucked: two tentacula are detached to the root of this trunk. Between the latter is a pointed ſcale, ſometimes employed to cut the veſſels from which the fluid is to be ſucked, but often ſerving only to cover other pieces, which are much ſharper and more appropriate to this function. In the ſtratyomys, and the common flies, there is merely a ſingle ſhort point under the ſcale. The ſyrphi and rhingiæ have in addition a ſtiff briſtle under each palpus. In the rhagio there are three briſtles under the ſcale, and the middle of them is the ſtrongeſt. The tabani have four, all pointed and ſharp like the blades of lancets; hence theſe inſects have the power of inflicting the ſevereſt wounds on the ſkin. All the parts are much elongated in the genera empis and bombylius; the trunk is more particularly extended than the briſtles in the latter, which indeed have only one briſtle under the ſcale. In the empis all the parts are equally prolonged, and there are four briſtles.

In the myopa (conops, Linn.) the trunk is elongated into a ſlender tube with an angle at its middle; there is a ſhort ſcale without any briſtle. In the aſilus and ſtomoxys (conops, Linn.) the trunk is hardened, and aſſumes a horny texture, ſo that it is capable of cutting. There is a ſingle briſtle within it in the ſtomoxys, and three in the aſilus. The trunk is reduced almoſt to nothing in the hippoboſca; and the ſingle briſtle is long and flexible.

All theſe genera have palpi of a ſingle piece. The tipulæ and culices have them articulated, and often very long; the trunk of the tipulæ is ſhort, with large lips, and no briſtle; that of the culices is long, ſlender, and contains a fine briſtle.

In the œſtri, all the external organs of the mouth are withdrawn within the head, ſo as to expoſe externally only three rather prominent points.

The hemiptera (rhyngota, Fabr.) are more uniform in the ſtructure of theſe parts than the diptera; in general they have a tube compoſed of ſome articulated pieces, and open above in its whole length. This tube contains three fine briſtles nearly as long as itſelf; it exhibits ſcarcely any other varieties except in its poſition and inflexions.

The lepidoptera (gloſſata, Fabr.) are equally uniform in the ſtructure of theſe parts: their tongue is formed of two membranous plates, curved tranſverſely in their whole length, ſo as to form a tube, and, when the inſect does not employ it, convoluted ſpirally, and lodged between two flat villous palpi, compoſed commonly of three pieces. The differences depend on the variable length of this organ, which is ſometimes very inconſiderable, and on the figure of the palpi: they are not of importance in connection with our preſent ſubject.

Among the aptera, the louſe has only a ſimple and ſhort ſucker, incloſed in a ſmall prominence: the flea has one with two briſtles, incloſed in a ſheath of three pieces, opened longitudinally above.

Inteſtinal Canal.—It is ſtraight in the cruſtacea, and uniform in its ſize, with the exception of the ſtomach. The latter is very different in the cruſtacea decapoda, and in the branchiopoda, it poſſeſſes, in the former, a ſingularity of ſtructure, which is remarkable as the only example of the kind in the whole animal kingdom; that is, it is ſupported by a bony apparatus, a ſpecies of ſkeleton, and conſequently does not collapſe when empty. The deſtination of this apparatus is not leſs extraordinary than its exiſtence; it ſerves to ſupport five hard and moveable teeth, which perform in the cavity of the ſtomach a true maſtication. They are placed before the pylorus, and allow no ſubſtances to paſs through that opening until they are perfectly triturated.

The ſtomach is found in the thorax above the mouth, and the œſophagus communicates with it by a large aperture. The anterior portion is more capacious than the poſterior, and the teeth are placed where the cavity begins to grow narrower. On the ſuperior ſurface, or that which is oppoſed to the mouth, there is a thin tranſverſe plate occupying the middle of the ſtomach. This ſupports the firſt tooth or bony oblong plate, conſolidated to the ſuperior ſurface of the ſtomach, directed towards the pylorus, and terminating behind in a tubercle.

On this poſterior extremity is articulated a ſecond plate, directed backwards, bifurcated like the letter Y; and on each of its lateral diviſions another is articulated, which turns forwards and outwards, and reaches the lateral extremity of the firſt tranſverſe plate. The two largeſt teeth are fixed on theſe two lateral pieces. They are oblong, have flat crowns, which are grooved tranſverſely, and the grooves and inequalities vary in the different ſpecies. In the cancer pagurus of Linnæus, the crown is finely ſtriated, has large denticuli at its lower edge, and a prominent part in front which is not ſtriated. In the lobſter there are nine tranſverſe ribs, of which the three front are much the largeſt.

From the point of union of the tranſverſe portion with the lateral of each ſide, another lateral piece is continued, proceeding lower than the firſt, and having at its extremity a lateral tooth ſmaller than the preceding, placed rather before and below its anterior extremity, and having three and ſometimes even five ſmall, ſharp, and bent points. The two ſmall teeth with curved points ſeize the nouriſhment which comes from the mouth; they convey it between the two teeth with flat crowns, which bruiſe it between each other and againſt the firſt ſingle plate.

When it has undergone this operation, the aliment paſſes through the narrow part of the ſtomach, where its courſe is ſtill interrupted, firſt by a fleſhy oval prominence correſponding to the interval of the two large lateral teeth, and afterwards by a ſharp criſta, which divides the pylorus into two half canals.

There are muſcular fibres in this ſtomach, which approximate the bony pieces, and the teeth which they ſupport; there are exterior muſcles which ſeparate the teeth from each other, and are attached to the neighbouring, and particularly the lower parts of the thorax. Theſe muſcles muſt be ſubject to the will, which is another remarkable ſingularity belonging to theſe ſtomachs.

Theſe teeth are diſcharged from the ſtomach when the old ſhell is ſhed; and are ſupplied by new ones.

After this large ſtomach, which is always dilated, comes a very ſlender inteſtine, which takes a ſtraight courſe to its termination at the end of the tail. Towards its middle a thick ring is obſerved, on the inſide of which there is a ſtrong valve, and the commencement of a very long cæcum.

Theſe circumſtances have been aſcertained in thoſe cancers which have long tails, as the cray-fiſh and the lobſter, alſo in the paraſitical ſpecies (the hermit crab), and in the crabs, as the cancer pagurus, puber, and mænas: the ſtructure may therefore be conſidered as common to all the cruſtacea decapoda. The branchiopoda poſſeſs a ſmall membranous ſtomach, ſhaped like a triangular priſm, furniſhed on each ſide of its poſterior extremity with a row of ſmall pointed teeth, and followed by a very thin inteſtinal canal, continued from one end of the body to the other, and nearly uniform in ſize throughout.

In the oniſci the front of the canal is a little ſwollen compared to the continuation.

In the reſt of the claſs of inſects we find as many varieties in the ſtructure of the alimentary canal, as in all the claſſes of vertebral animals together. There are not only differences between the families and ſpecies, but often very conſiderable ones between the larva and perfect ſtates of the ſame inſect: and all theſe varieties bear a very accurate relation, which in many caſes can be very clearly appreciated to the animal's kind of life, whether of ſhorter or longer duration. Thus the voracious larvæ of the ſcarabæi and butterflies have inteſtines ten times as large as the winged and ſober inſects, if we may be allowed to uſe that term, to which they give birth.

There are the ſame general reſemblances in the natural families of inſects, as in the reſt of the animal kingdom; thus all the coleoptera lamellicornia, all the carnivora have ſimilar inteſtines in each of their ſtates, &c. Here, as in the other claſſes, the length and complication of the inteſtinal canal indicate a vegetable nouriſhment; ſhortneſs and thinneſs, on the contrary, ſhew that the animal is carnivorous, &c.

I. *In the Coleoptera.*—We ſhall ſelect for deſcription ſome very natural families, which are remarkable for any peculiarities of ſtructure, and ſhall notice together the inteſtinal canal of the larva and of the perfect inſect, in order to exhibit in the cleareſt view the very ſtriking difference between theſe two ſtates.

1. In the coleoptera lamellicornia. The laſt mentioned

point is very clearly exemplified this family. The larvæ of all the genera, which compoſe it, have a large and ſhort alimentary canal, divided into the following parts. 1. A ſhort and weak œſophagus. 2. A ſtraight cylindrical ſtomach, tolerably thick and muſcular, ſurrounded by three circles of ſmall cæca, placed, one at the commencement, one at the middle, and the third at the end of the cylinder. Theſe cæca are numerous, weak, and ſhort: thoſe of the third circle are ramified in the larvæ of the ſcarabæi properly ſo called (les geotrupes of Latreille). In the melolonthæ the cæca of the firſt circle have ſmall lateral denticulations, which may be regarded as ſo many ſmaller cæca. The upper and lower circle in the lucani are compoſed of a ſmall number of large cæca, while the middle is made up of very numerous ſmall ones. Probably they all ſecrete and pour into the ſtomach ſome diſſolving fluid. 3. A ſhort inteſtine of much thinner ſides, and rather ſhorter in length than the ſtomach. Its origin, which is rather expanded, receives above the hepatic veſſels; it terminates at the poſterior extremity of the body of the larva. 4. An enormous colon, or large inteſtine, three times as large as the ſtomach, and filling all the poſterior third of the body. It poſſeſſes two ſmooth bands, between which are tranſverſe folds, producing a cellular appearance like that of the human colon. Its courſe is in a direction contrary to that of the ſmall inteſtine; that is, it returns from behind forwards, and lies upon that inteſtine. 5. A rectum turning from before backwards upon the colon, in order to terminate at the anus. It is ſlender and ſtraight, without any inequality.

We ſhould have expected that the perfect inſect would retain ſome trace of ſuch ſtrongly marked peculiarities; yet there is really no veſtige of them diſcernible. All theſe inſects, lucani, ſcarabæi, melolonthæ, cetoniæ, have a long ſlender canal, four or five times longer than the body, very much convoluted, and poſſeſſing hardly any dilatation. Sometimes the anterior portion is merely a little larger and folded tranſverſely.

2. In the coleoptera carnivora. As the habits of theſe animals are very different from thoſe of the preceding, their alimentary canal is different in both ſtates. In the perfect ſtate it conſiſts, of, 1ſt, a long and very dilatable œſophagus. 2. A firſt ſtomach, nearly ſpherical in its ſhape, with muſcular parietes and tranſverſe wrinkles. 3. A ſecond ſtomach, membranous, elongated, and villous; not on the inſide, as thoſe of certain vertebral animals are, but on the outſide. The villi are veſſels which draw, from the ſurrounding nutrient fluid, the gaſtric juice which they pour into the ſtomach, according to the laws of ſecretion in inſects; conſidered as animals which have no circulating organs. 4. An inteſtine of moderate length, between once and twice the length of the body, ſmall and uniform in its diameter throughout. 5. A conical and rather long cæcum inſerted near the anus. Near the margin of the anus are found two veſicles, which ſecrete the acrid fluid almoſt conſtantly voided by theſe animals when they are ſeized.

Such is the ſtructure of the genera ſeparated from the carabi, the cicindelæ, and the dytiſci: their larvæ have no dilatation like a ſtomach; their canal is ſmall, all of one ſize from the mouth to the anus, and about one-half longer than the body. A cæcum, however, may be obſerved near the anus in the larvæ of the dytiſci.

3. In the coleoptera clavicornia. The hydrophilus piceus, in its perfect ſtate, has very long cylindrical inteſtines (four or five times longer than the body), uniform in ſize throughout, and forming large convolutions in the abdomen. The larva, which is much more carnivorous, has ſhort inteſtines (half as long again as the body), of which nearly two-thirds form an elongated ſtomach, villous externally; the reſt is ſmooth, and divided by a contraction into two parts. The ſilphæ, on the contrary, have in their perfect ſtate ſuch a ſtomach, followed by a ſmall inteſtine twice as long as the body.

4. In the coleoptera lignivora. The larvæ of the prioni and cerambyces have very large inteſtines, with their ſides nearly uniform throughout, and forming four folds, each of which is as long as the body. The commencement, which alone can be compared to a ſtomach, is rather corrugated tranſverſely like a colon. The perfect inſect has firſt a membranous and round ſtomach, then an oval one, which is inſenſibly contracted into a cylindrical canal, ſuddenly growing ſmaller at the inſertion of the hepatic veſſels, and continuing ſo to the anus. The whole canal is at moſt twice as long as the body.

The larva of the lamia, Fab. has firſt a very diſtinct ſtomach, then a knotted ſmall inteſtine, which is ſuddenly changed into a large inteſtine longer than itſelf.

5. In the coleoptera filicornia, of the family of the veſicantiæ, the meloe poſſeſſes an enormous oval ſtomach, filling nearly the whole abdomen. The front is covered with ſtrong circular fibres; and a cylindrical valve, analogous to the valvula coli of man, is obſerved at the cordia.

In the family of the lucifuga, the tenebrio has a cylindrical elongated ſtomach, a firſt inteſtine, which is rather ſlender, and another ſomewhat larger. The whole canal is about three times the length of the body. The blaps has a muſcular cylindrical ſtomach, another equally large but membranous, ſeparated from the former by a ſlight conſtriction, and a ſmall inteſtine which is a little enlarged towards the anus. The proportionate length of the whole is about the ſame as in the laſt inſtance.

6. The brachelytra, or ſtaphylini, reſemble the carnivora in the villoſity of the ſtomach, as they do in their habits.

II. *In the Orthoptera.*—Theſe, in the claſs of inſects, ſeem analogous to the ruminants among the quadrupeds, at leaſt in reſpect to the complication of the ſtomach, and ſome ſuppoſe that their aliment may be ſeen brought back into the mouth for the purpoſe of a ſecond maſtication. As they undergo an imperfect metamorphoſis, their alimentary canal is the ſame in the larva as in the perfect ſtate. It conſiſts in general of the following parts. 1. An œſophagus of the uſual kind. 2. A firſt membranous ſtomach. In moſt genera this is a ſimple dilatation of the œſophagus, of which the internal membrane is ſmooth and folded longitudinally. In the locuſta it is rather, and in the blatta conſiderably larger than in the other genera. In the acheta it is an oval bag, having quite a lateral poſition, connected to the ſide of the œſophagus like a cæcum, with one opening for the reception and diſcharge of its contents. 3. A ſecond ſtomach or gizzard, ſmall, nearly round, poſſeſſing a very thick muſcular coat, and armed internally with ſcales or teeth. In the locuſta and acheta theſe are longitudinal rows of fine and numerous ſcales, placed one over the other like the tiles of a roof, and directed backwards. In the blattæ there is a ſingle row of ſix or eight large curved teeth, denticulated like the bills of birds of prey, and directed backwards. 4. The cæca or third ſtomachs are immediately round the poſterior orifice of the gizzard, and vary in number. The locuſta and acheta have two large ones, and this has given riſe to the remark that the grylli have four ſtomachs like the ruminating mammalia. The internal membrane is much folded, and its extremity receives many ſmall ſecretory veſſels, which pour out gaſtric juice. There are five of theſe cæca in the gryllus, and eight or ten in the blattæ. 5. The inteſtinal canal varying in length and diameter.

The earwig is ſaid to be very different from the other orthoptera in having only a ſimple elongated ſtomach, a very ſhort inteſtine, and a dilatation with longitudinal folds near the anus.

III. *In the Hymenoptera.*—The bees have a firſt ſtomach, which is membranous and tranſparent, pointed in front, large and divided into two portions behind. In this organ the nectar of the flowers is converted into honey: it is the reſervoir of this matter, which they depoſit in their hives by the act of vomiting. The ſecond ſtomach proceeds from the interval of the two diviſions; it is elongated and ſwollen laterally towards the middle. The hepatic veſſels are inſerted immediately after the pylorus. The firſt inteſtine is ſmall, and ſcarcely equal in length to the ſecond ſtomach: the rectum is large but ſtill ſhorter.

The firſt ſtomach of the waſp is ſmaller; the ſecond longer, and particularly much more muſcular. The larvæ of both genera have an immenſe cylindrical muſcular ſtomach, filling nearly the whole abdomen, and followed by a very ſhort inteſtine.

In the ſphex the ſtructure reſembles that of the bee; the parts are only larger in proportion to their length.

IV. *In the Neuroptera.*—The family of the odonatæ, which is truly carnivorous, has very ſhort inteſtines in its three ſtates: they do not exceed the length of the body. In the libellula grandis, Linn. a ſhort œſophagus is ſucceeded by a ſmall oval muſcular ſtomach, ſtriated longitudinally; then comes a ſtraight large inteſtine or ſecond ſtomach, with a conſtriction placed far back at the entrance of the hepatic veſſels. The interval between this part and the anus is very ſhort, and folded longitudinally. In its larva, the œſophagus has a circular dilatation: the conſtriction of the cordia produces a kind of valve. From this point the canal has a bright yellow colour, as far as the inſertion of the hepatic veſſels; its laſt portion is white and much thicker; and contains the ſingular reſpiratory apparatus, which we ſhall deſcribe afterwards.

In the family of the agnatha, the ephemera, during its larva ſtate, has merely a ſtraight uniform canal, without any convolution, which becomes extremely thin in the perfect inſect.

V. *In the Hemiptera.*—Theſe poſſeſs in general a ſimple, oval, and muſcular ſtomach, of conſiderable ſize, followed by a ſmall inteſtine of moderate length, near the end of which is a ſmall cæcum. Such at leaſt is the caſe in the nepa, notonecta, &c.

VI. *In the Lepidoptera.*—The caterpillars have a large, ſhort, ſtraight, inteſtinal canal, without any conſiderable inequalities. The œſophagus is the ſlendereſt portion, the ſtomach is elongated and contracted at the pylorus. After the pylorus the inteſtine is larger than in the reſt of its length; it is contracted towards the anus. At the latter part it has the ſtrongeſt circular fibres; on its parietes other fibres are found, variouſly decuſſated and ending in two white lines, which extend over its whole length, one above, and the other below. The diameter varies in different ſituations, according as the contents are accumulated. Sometimes the diſtinction between the ſtomach and inteſtine can ſcarcely be obſerved.

This canal is obviouſly calculated for ſolid and abundant food. The butterfly, which ſubſiſts entirely on the juices of vegetables, has a very different digeſtive apparatus. Among the diurnal inſects of this order, the atalanta has a ſlender œſophagus, with a membranous dilatation on its ſide, like a crop, more or leſs rounded in its figure, and often full of air. Then comes a ſecond elliptical membranous ſtomach, the ſides of which preſent many hemiſpherical cellular prominences; and afterwards a third, cylindrical, and rather muſcular, followed by a ſmall inteſtine of moderate length, terminated by a rather larger rectum.

VII. *In the Diptera.*—In general their inteſtinal canal is tolerably long in both ſtates. It is five times the length of the body in the larva of the ſtratyomys, and conſiſts of a ſhort œſophagus as ſlender as a thread, a very ſmall oval ſtomach, and an inteſtine, of which the firſt half is wrinkled tranſverſely, which becomes afterwards larger and ſmoother to the inſertion of the hepatic canals, below which it is ſuddenly conſtricted and remains narrow. The differences between this and the larva of the ſyrphus are very ſlight; and the diſtinctions between both and their perfect inſects are not more obvious. However, Swammerdam repreſents four ſmall cæca, after the ſtomach, in the larva of a fly which inhabits cheeſe; Cuvier has not found them in the diptera diſſected by himſelf.

VIII. *In the Gnathaptera.*—The ſcolopendræ have a long canal contracted behind; the iuli have an equally long and cylindrical one. We have already mentioned that of the oniſcus.

IX. *In the Aptera without Jaws.*—The louſe has two ſmall ſwellings at the origin of the ſtomach, which is elongated; the inteſtine is not longer than the ſtomach; it is ſmall, and terminated in front of the anus by a muſcular enlargement.

Hepatic Veſſels.—Although the cruſtacea have a heart and blood-veſſels, moſt of them have not a liver, properly ſo called. The organ which produces bile in them conſiſts of a conſiderable number of ſmall tubes ending in cul-de-ſacs. The ſtructure is analogous to that of the pancreas of fiſhes, which conſiſts, as we ſuppoſe, of the multitude of cæca opening at the origin of the inteſtine.

The appearance of the hepatic cæca in the cruſtacea diſcloſes their nature and office; they are yellow, have ſpongy ſides; produce a brown and bitter liquor, which gives its peculiar taſte to the ſoft ſubſtance in the body of the lobſter; for the hepatic cæca, with the ſtomach, fill nearly the whole thorax of theſe animals; and, in the hermit crab, they fill alſo a great part of the tail.

The ſquilla, Fab. is an exception to this rule; theſe animals have a liver of a firm texture, very much reſembling a conglomerate gland, conſiſting of lobes arranged on each ſide of the alimentary canal in its whole length.

In the inſects, properly ſo called, there is ſtill leſs appearance of liver than in the common cruſtacea. Since they can have no glands on account of the abſence of blood-veſſels, the bile, like all the other ſecretions, is produced in them by fine veſſels with ſpongy ſides, floating in the fluid, which bathes all the parts, and deriving from it, by the organization of their tiſſue, the elements proper for the formation of this liquor.

Theſe veſſels exiſt equally in the larva and in the perfect inſect: the fluid, which they form and contain, tinges them with its own colour. They are uſually yellow, ſometimes, as in the ſcarabæi and cerambyces, of an opaque white; and in other inſtances, as in the dytiſci, of a deep brown. Their bitter taſte ariſes from this fluid, which would probably be found to poſſeſs many of the qualities of bile, if it could be procured in ſufficient quantity for analyſis.

The number of theſe veſſels is variable; when it is large, they are ſhort, ſo that the extent of ſurface is nearly the ſame. Sometimes they all end in a common excretory tube, which terminates in the inteſtine. This is the caſe with the gryllo-talpa. They are commonly inſerted after the ſtomach, but ſometimes not till near the middle of the inteſtinal canal, as in the grylli; or even towards its end, as in the libellulæ. The oniſci alone have them inſerted near the œſophagus; in theſe inſects they are only four in number, large, undulated, as long as the body, and of an orange colour.

Among the neuroptera, the libellulæ have a conſiderable number of ſhort ones, ſurrounding the inteſtine at a ſmall diſtance from the anus, where it becomes large. The ſame ſtructure exiſts in the common grylli. In the gryllo-talpa there is a large packet of theſe veſſels, terminating by a common canal in the middle of the large inteſtine. The larvæ and the perfect inſects have the ſame ſtructure in theſe genera. This reſemblance ſeems moreover to exiſt, with reſpect to the hepatic organs, even in orders where the metamorphoſis is the moſt complete in all other parts; the number at leaſt is not changed. It is conſiderable in the hymenoptera, but generally amounts only to two in the coleoptera. In the latter they are generally found parallel to the inteſtinal canal, and make numerous windings. Their inſertion is immediately after the ſtomach in the larvæ of the ſcarabæi, the dytiſci, the carabi, &c.

The caterpillars and the perfect inſects produced from them have two, each of which is ſub-divided into three, placed in the former, at the ſides of the poſterior half of the canal, and forming their principal folds completely in the back of the body. Among the hemiptera, the nepæ ſeem to have only two. The larvæ of the ſtratyomys and ſyrphus, of the order diptera, have four, which end in the inteſtine by a common trunk.

Coverings and Supports of the Alimentary Canal.—We have mentioned already that the ſtomach of the cruſtacea is ſupported in its ſituation by its muſcles; the remainder of the canal is maintained only by veſſels, and by the compreſſion of the ſurrounding parts.

In the proper inſects, the inteſtinal canal is retained in its place by the tracheæ only; there is neither meſentery veſſel nor cellular ſubſtance; conſequently when an inſect is opened and placed in water, all the folds of its canal riſe, and are developed from the ſpecific tightneſs derived from the air in the tracheæ.

The fine membrane lining the abdomen, and enveloped by the rings of the ſkin and their muſcles, may be called peritoneum.

But the moſt remarkable circumſtance belonging to inſects in their larva ſtate, and exiſting in them excluſively, among all invertebral animals, is the portions of cellular texture filled with fat, which may be compared to omenta, and may have the ſame functions. They ſeem particularly deſigned to ſupply the materials of nutrition to the animal, during all that time, in which, as a chryſalis, it eats nothing, as the fat of the omenta ſupports life in thoſe quadrupeds, which paſs the winter in a lethargic ſleep. When the animal changes its coverings and its form, and becomes a perfect inſect, theſe fatty organs probably furniſh the prodigious quantity of materials, which the ſudden developement of ſo many parts muſt require; conſequently they are not found in the latter ſtate.

The forms, colour, and conſiſtence of theſe maſſes vary. In the caterpillars they are oblong, ſwollen, full of a white fat like cream. In the larvæ of the ſcarabæi they are large ſemi-tranſparent membranes, with many opaque and white grains; in thoſe of the flies and ſtratyomys they have a flaſhed appearance, like narrow ribbands irregularly joined. They are inconſiderable, or do not exiſt at all, in the larvæ of inſects, which undergo an incomplete metamorphoſis, which eat during their whole exiſtence, and never paſs into the chryſalis ſtate. In all the orders they receive numerous air-veſſels.

Abſorption in Inſects.—The nutritive fluid prepared in the alimentary canal is taken up by a particular order of veſſels, called abſorbents, in the four firſt claſſes of the animal kingdom; theſe convey it into the blood-veſſels, in which it paſſes to all the organs of the body. The application of the new matter furniſhed by digeſtion to the parts of the ſyſtem is performed in ſome other way in inſects, as they ſeem to have neither abſorbing nor blood-veſſels (excepting the cruſtaceous inſects).

Cuvier is of opinion that the nutritive proceſs is performed in this claſs by *imbibition.* We arrive, ſays he, at this concluſion by proofs of different kinds; ſome are direct, but negative; others ſupply only inductions; their union will probably ſuffice to produce conviction. In the firſt place, he continues, no veſſels are found in diſſecting inſects; I have ſought for them with the greateſt attention, and by the aſſiſtance of the microſcope, in thoſe organs, which in other claſſes contain them in the greateſt abundance, as the choroid coat of the eye, and the membranes of the inteſtinal canal; I have never found any thing like them, although the tracheæ and the nerves are very eaſily diſcovered, and the innumerable ramifications of the former may be traced with the naked eye. Lyonet, who has deſcribed and repreſented in the larva of the coſſus parts a thouſand times ſmaller than the principal blood-veſſels would be, could never diſcover any thing of that kind.

There is indeed in inſects an organ, to which many anatomiſts have given the name of heart; it is a membranous tube, continued through the whole length of the back, both in the larva and in the perfect ſtate, exhibiting alternate contractions and dilatations, which ſeem to paſs ſucceſſively from one extremity to the other; but, notwithſtanding this circumſtance, which ſeems to indicate an organ of circulation, this tube produces no branches, and we can neither attribute to it the functions of a heart, nor diſcover any other purpoſe to which it is ſubſervient. Laſtly, thoſe naturaliſts who have obſerved with the microſcope the tranſparent parts of inſects, have diſcerned only a fluid at reſt, bathing them on all ſides.

Such are the negative arguments on this ſubject; thoſe drawn from induction refer principally to two points; *viz.* the mode of reſpiration in inſects, and the form of the ſecretory organs.

In animals which have a circulation, it is continually collected in a central reſervoir, whence it is forcibly expelled to all parts; it always arrives at the organs from the heart, and it is always ſent to the heart before it comes back again. It may then have been modified from its ſource by the action of the air; and, in fact, before it is brought by the aorta and its ramifications to the parts which are to be nouriſhed by it, it circulates through the lung or gills. If this arrangement is not found in inſects, the reaſon probably is that their nutritive fluid is not contained in veſſels, that it does not come from a common ſource, and conſequently that it could not undergo any modification in a ſeparate organ before arriving at the parts. It continually and quietly bathes all the parts, which are to draw from it ſubſtances ſuited to their wants; the action of the air ſhould therefore reach it every where, and this point is very completely ſecured by the diſpoſition of the tracheæ, as there is no point of the body to which the fine ramifications of theſe veſſels do not penetrate, and where the air does not immediately exerciſe its chemical action; in a word, as the blood cannot go in ſearch of the air, the air is every where brought in contact with the blood.

The ſecretions of inſects are never performed by conglomerate glands; their organs conſiſt, in all caſes, as we have juſt ſeen in the example of the liver, of long and ſlender tubes, floating in the cavity of the body, without being connected together, or fixed in any way except by the tracheæ. This appears clearly to be a neceſſary conſequence, and therefore a very probable indication of the abſence of blood-veſſels. When the powerful agents of circulation exiſt, they convey with facility the nutritive fluid to the moſt remote points of the glands; the intertexture of the blood-veſſels forms a thick and cloſe tiſſue, in which the peculiar veſſels of the gland are placed. When, on the contrary, there is neither heart nor blood-veſſels, nor any force to impel the fluid towards the ſecretory organs, the latter require a more powerful attractive force; and as this can be exerted only by means of the tiſſue compoſing their ſides, it becomes neceſſary that they ſhould be unattached, looſe, long, and ſlender, in order to augment their ſurface.

Organs of Circulation in the Cruſtacea.—The heart of the cruſtacea decapoda is very differently formed from that of the branchiopoda. In the former it is oval, circumſcribed, and placed nearly in the middle of the thorax; in the others it is elongated, and extends from one end of the body to the other, ſo as to form apparently a connecting link between the heart of the decapoda and the dorſal veſſel of the other inſects. In this point of view it has led ſome naturaliſts into error: we ſhall, however, find a ſtructure which is more analogous to it in the red-blooded worms.

The decapoda (the crabs, lobſter, cray-fiſh, hermit crab, &c.) have an aortic heart, like that of the molluſca. It receives the blood from the branchiæ by a large veſſel, which lies longitudinally in the cheſt to receive this blood by lateral veſſels. Cuvier ſtates that this is the caſe in the hermit crab; but he thinks that in the lobſter the branchial veins form two trunks, which go directly to the two ſides of the heart. When one of the veins of the branchiæ is injected, the fluid arrives at the heart by the route juſt indicated. From the ſame poſterior part of the heart ariſes an arterial veſſel, which goes directly backwards, and ſupplies the organs of generation and the muſcles of the tail. The anterior portion produces other arteries, varying in number according to the ſpecies.

Each pedicle of the branchiæ contains two principal veſſels; an artery and a vein. The venous trunks all go to the heart; and, as we have already ſtated, by a ſingle trunk in the decapoda: but, in the branchiopoda, where the heart is elongated, they all terminate in it directly, ſo that a pair of veins enters at each ring of the body. The branchial arteries do not come from the heart. When the latter organ is injected, the fluid does not enter the branchiæ, although it will paſs eaſily from the latter to the heart. In the ſquilla faſciata, Fabr., Cuvier obſerved a large longitudinal vena cava, extending from one end of the body to the other, under the inteſtine, and conſequently on the oppoſite ſurface to that occupied by the heart. Its tiſſue is much thinner than that of the heart, and tranſparent, and it produces as many pairs of branchial veſſels as the heart receives from thoſe organs. This anatomiſt has very little doubt that the ſame veſſel will be found in the decapoda, but he had not examined them for this purpoſe ſince he firſt ſaw it in the other diviſion.

The circulation of the cruſtacea is then the ſame with that of the gaſteropodous molluſca; *viz.* a double circulation, of which the aortic ſyſtem only poſſeſſes a ventricle: and even this ventricle does not deſerve the name in the branchiopoda, it ſo much reſembles in them a veſſel by its elongated form. Under this point of view the circulating ſyſtem of theſe animals reſembles that of red-blooded worms.

The heart of the cruſtacea, even in the decapoda, has no auricle; and valves have not hitherto been obſerved in it

It is hardly neceſſary to ſtate, that the blood thrown by the heart into the arteries, paſſes through the veins into the vena cava.

The motions of the heart may be ſeen in the ſmall monoculi of this country, but their extreme ſmallneſs prevents us from following the diſtribution of the veſſels. The anatomy of the molucca crab is not yet known.

Circulation of Inſects.—All inſects have in their back a longitudinal veſſel, filled with a tranſparent fluid, and for a long time regarded as the heart, after the ſtatement of Malpighi, who deſcribed it in the ſilk-worm, and repreſents it as a knotted canal, that is divided at intervals by conſtrictions. He conceived that each dilatation was a particular heart, and that theſe different organs tranſmitted the blood to each other: but he remarked at the ſame time that the ſucceſſion of the pulſations was not regular, and that the fluid ſometimes took a retrograde courſe. Lyonet has given a better account of this dorſal veſſel. It is an uniform canal, proceeding from the head to the oppoſite extremity, and enlarging a little in its courſe, but cloſed at the two ends. It poſſeſſes on each ſide a certain number of tranſverſe muſcular faſciculi, ſomewhat in the form of wings, which are fixed by their oppoſite ends to the general covering. Its dilatations and contractions are produced by theſe, which are exterior muſcles, and not by its own tiſſue.

Lyonet aſſures us, that he has not been able to diſcover any veſſel produced from this, and proceeding into the body, although he has deſcribed tracheæ and nerves a thouſand times ſmaller than theſe veſſels muſt be if they exiſt. Cuvier has tried all known methods of injection, without any greater ſucceſs. Swammerdam indeed mentions that he injected ſmall veſſels from it in the grylli; but we cannot help entertaining doubts on this ſubject, until the experiment ſhall have been repeated with ſucceſs.

The dorſal veſſel of inſects cannot then in any manner perform the functions, nor deſerve the name of a heart. Perhaps, like all other parts of this kind in inſects, it is a ſecretory veſſel: but we are at preſent quite unable to determine what liquor it ſecretes, and for what uſe. Its contents are tranſparent, light yellow, viſcous, miſcible with water, eaſily dried, and then becoming hard and cracking like gum.

Beſides the analogy of its contractions, its ſituation might favour the idea of its being a heart. The latter organ is placed near the back in almoſt all the molluſca, and in all the cruſtacea; and this is the poſition of an organ, which can hardly be regarded in any other light than as a heart, in the arachnidous inſects (araneæ, phalangia, and ſcorpions). It may be obſerved very eaſily in the ſpiders: and may be ſeen beating through the integuments of the abdomen in the ſpecies which have ſmooth bodies. On removing the integuments we expoſe a hollow oblong organ, pointed at its two ends, and advancing as far as the thorax by its front end: two or three pairs of veſſels very manifeſtly paſs off from its ſides. If we add to this account, the fact, that the ſpiders have no tracheæ, but that their reſpiration is circumſcribed within a ſmall number of veſicles, and that they appear to have glands, we ſhall be induced to believe that their circulation is more complete, and more analogous to our's than that of other inſects.

Reſpiratory Organs.—The claſs of inſects exhibits two very different arrangements of the organs belonging to this function: the cruſtacea have gills, reſembling thoſe of fiſhes and of many molluſca; other inſects have air-veſſels diſtributed to all parts of their bodies. The branchiæ of the former extract air from the water in which they live, in the ſame way as the gills of fiſhes act. The reſpiration of inſects produces in the air the ſame effects as that of the warm-blooded animals. Experiments ſhew us that oxygen is conſumed in this caſe, and that the reſidue of the air is rendered impure, by the admixture of carbonic acid gas.

An important reſult of reſpiration ſeems to be the maintaining the irritability of the moving powers: hence the definitive reſult of this proceſs, with reſpect to the fibre, is power in executing the motions which it has to perform. Thus the energy of the motive force will be in proportion to the quantity of reſpiration. The organization of inſects corresponds to this theory: they are the only claſs among the lower ranks of animated exiſtence, which poſſeſſes the faculty of flying, and we conſequently find the tracheæ carrying air over the whole body, ſo that reſpiration is carried on at all points. In thoſe inſects which do not fly, the force of the muſcles may be eſtimated by the rapidity of their other motions. The running of the millepede and the jumping of the flea, ſhew that they belong to a very irritable claſs of animals; the caſe is analogous to that of the oſtrich and caſſowary, which run with great celerity, although they are birds without wings.

Reſpiration of the Cruſtacea.—Their branchiæ are larger in proportion than thoſe of moſt of the mollusca. In the decapoda they are attached to the baſe of the feet, under the lateral and deſcending edge of the thorax, which confines them within a narrow ſpace. The branchiopoda have no gills in this ſituation, but under the tail, between the fins, and floating looſely in the water.

In the crabs the ſtructure is in ſome reſpects peculiar. Each gill repreſents a triangular elongated pyramid, attached by its baſis only, and having the point directed upwards. The middle of the pyramid is divided by a plane, proceeding from the apex to the baſis, and compoſed of a double membrane; and the body of the pyramid is formed by a large number of plates placed one over the other, perpendicular to the vertical plane juſt mentioned, and conſiſting merely of doublings of the double membrane. A large veſſel runs along each of the two longitudinal edges of this plane, and penetrates at its baſis into the thorax of the animal; one of theſe is arterial, and the other venous. If we inflate them, immediately all the ſmall laminæ which compoſe the pyramid are diſtended with air. In the ſame way the blood is expanded over all the ſurfaces, and is thus favourably diſpoſed for the action of the water.

There are ſeven of theſe pyramids on each ſide. As the edge of the thorax, which embraces and confines them, is inflexible, a particular mechaniſm became neceſſary for renewing the water which waſhes the ſurface of the organs. This effect is ſecured by two plates of a ſubſtance reſembling parchment, articulated on the cheſt near the maxillæ, very elongated, and paſſing obliquely, the one within, between the branchiæ and the body, the other without, between them and the edge of the cheſt. By compreſſing the branchiæ, theſe plates ſqueeze the water from the intervals of the laminæ, and when the preſſure is remitted, they allow the introduction of a new portion of fluid.

The branchial pyramids, although placed in a ſimilar ſituation, are more numerous and complicated in the decapoda with long tails, as the lobſter, cray-fiſh, and palinurus, Fabr. They have rows of cylindrical filaments, inſtead of laminæ, piled on each other on the two ſides of the vertical plane; ſo that their ſurfaces reſemble the ſhag of velvet. There are ſeveral thouſands of theſe filaments in a pyramid; each of them is formed of an artery and a vein united: each pyramid has two, its large artery and large vein ending in the body.

Theſe villous pyramids of the long-tailed decapoda are arranged in groups, between vertical laminæ, of which one aſcends behind each group. Theſe laminæ are attached to the firſt articulations of the feet, which cannot move without moving them, and without either compreſſing or ſetting free the branchiæ. The lobſter and cray-fiſh have five groups of four pyramids each, and a ſolitary one before and behind, of which the anterior is very ſmall. This will make twenty-two gills on each ſide. The firſt group is attached to the moſt exterior pair of maxillæ: and the ſolitary pyramid in front to the pair concealed by the former. The ſecond group is connected to the claws, and the others to the following feet, except the laſt, which has only a ſolitary pyramid. In each group the exterior pyramid is attached to the pedicle of the parchment-like plate, and moves with it: the three others adhere to the body of the animal, and have no ſeparate motion. The firſt ſolitary pyramid is alſo attached to its plate; but the laſt is fixed to the body, and has only a rudiment of a plate behind it. Moreover, two other plates are attached to two maxillæ, anterior to thoſe of which we have already ſpoken, and ſupport no gills: yet they are placed obliquely againſt theſe organs, and contribute to their compreſſion and relaxation. The action of all theſe plates occaſions the expulſion at the two ſides of the mouth of all the water in contact with the branchiæ.

The tail of the branchiopoda, particularly of the ſquillæ, bears on its under ſurface five pairs of fins, forming broad membranous and ciliated oars, divided into two large lobes, an exterior, which is rather anterior; and an interior, which is a little poſterior. The gill is attached to the root of the firſt at its inner edge. It conſiſts at firſt of a conical pedicle compoſed of the two large veſſels: from this proceeds a row of cylindrical tubes, gradually diminiſhed in ſize from the baſis towards the apex: each of theſe is curved, and forms a long conical and flexible tail, which alſo ſupports a very numerous row of long and looſe filaments. Each gill contains a very conſiderable number of theſe, and reſembles, on the firſt view, a large bruſh: it is only by ſeparating the filaments that the regularity of their inſertion and ſucceſſion can be perceived. It is almoſt unneceſſary to add that each filament contains two veſſels; and that each tail and each tube has the ſame vaſcular arrangement, juſt as in the general pedicle. The branchiæ float in the water, are moved like the fins, and are even agitated between the two lobes of the latter: conſequently no mechaniſm is required for renewing the water in contact with them.

Tracheæ and Reſpiration of Inſects.—Some remarks on this ſubject will be found in the article ENTOMOLOGY, under the diviſion *Stigmata.* We ſhall enter here more minutely into the anatomical details.

We have already ſtated that the ſurrounding element, the air, diſtributed by means of an infinite number of tubes, exerts its action on all points of the interior of the body. Theſe canals have been called tracheæ, on account of their analogy to the trachea or large veſſel which conveys air into the lungs of ſuch animals as poſſeſs thoſe organs. Their ſtructure is remarkable: they are compoſed of three membranes, an internal and an external one of the common ſtructure; and a middle one compoſed of an elaſtic thread, poſſeſſing a fine metallic luſtre, rolled ſpirally, or in a double ſpiral courſe round the canal, from one extremity of the tube to the other, and admitting of being unrolled with a little addreſs. By this the ſides of the tube are conſtantly maintained circular, ſo that the paſſage of the air is always free. Yet all the tracheæ are not provided with this part in their whole length: ſome, which Cuvier calls veſicular, are dilated at certain intervals, ſo as to form merely membranous pouches not provided with this elaſtic ſupport.

The tracheæ communicate externally by ſmall lateral holes pierced on each ſide of the body, and called ſtigmata; or ſometimes by one or two tubes opening into the anus. The latter ſtructure belongs to the true aquatic inſects; ſome of which, as the larvæ and chryſalides of the libellulæ, have in the rectum a particular apparatus for this purpoſe, which we ſhall deſcribe.

The tracheæ of the larvæ do not reſemble thoſe of the perfect inſects any more than the other organs: indeed the differences in this reſpect are often ſtill more ſurpriſing.

We ſhall deſcribe the organs ſucceſſively in the moſt remarkable families.

Thoſe of the caterpillars are the beſt known, through the admirable deſcription given by Lyonet of that inſect. A nearly cylindrical tube, receiving air by ten ſtigmata, extends on each ſide of the body. Its branches go off in a radiating manner, from points exactly correſponding to the ſtigmata; thoſe at the beginning, which go to the head, are larger than the ſucceeding ones. We obſerve here, once for all, that no part is unprovided with theſe air-veſſels, and that the very membranes of their trunks even receive ſmall branches. In the caterpillar they are ſtrong, opaque, and of a fine ſilvery colour, which, however, depends in part on the contained air; for the brilliancy is loſt, both here and in other families, when they are macerated and filled with water or ſpirits of wine. The air-veſſels of the butterflies, produced from theſe caterpillars, have a very different appearance; they are thinner, leſs numerous, and poſſeſs almoſt throughout ſmall yellow or white elliptical bodies of a fatty nature: ſuch at leaſt is their appearance in the atalanta and the phalæna pavonia.

A much more conſiderable change is obſerved in the coleoptera lamellicornia: the larva has faſciculi of cylindrical, ſilvery, and very fine tracheæ, diſtributed from each ſtigma over the ſurrounding parts. In the perfect inſect they are of a dead white, ſwelled every where into ſmall oval or irregularly-figured veſicles, with very thin ſides: they reſemble trees much loaded with leaves. Examples of this arrangement may be ſeen in the melolonthæ, the ſcarabæi, the coprides, the lucani, &c.: and it occurs in no other families.

The hymenoptera and the diptera have two large veſicles at the baſis of the abdomen, and ſome ſmall ones: but the number is always inconſiderable.

The hydrophilus piceus has four large ones at the baſis of the abdomen; and, as this is a ſtrictly aquatic inſect, they may aſſiſt the animal, as the ſwimming-bladder of fiſhes does, in raiſing or depreſſing itſelf in the water.

The principal air opening in the aquatic larvæ is generally near the anus, that they may the more readily reach the air: in this caſe the two lateral trunks of the tracheæ are of great ſize, apparently for the purpoſe of holding a larger ſupply of the fluid; and the branches go off in the form of ſlender cylindrical threads. This arrangement is found in the larvæ of two very different families, the hydrophilus and ſtratyomys. The latter, as all the aquatic larvæ of the diptera, can elongate its tail conſiderably in ſearch of air without elevating the body; the anus is ſurrounded by ſmall tracheæ in the form of radii. Theſe inſects ſuſpend themſelves at the ſurface of the water by means of their tails.

The larvæ of the libellulæ exhibit the moſt ſingular diſpoſition of the reſpiratory apparatus. The orifices, which abſorb the air, are found in the rectum, under the form of very ſmall tubes, ranged in little groups in ten rows, which repreſent ſo many long pinnated leaves. A number of ſmall tracheæ, equal to that of the tubes within, paſſes from the rectum into the body; and theſe terminate in four trunks extended through the whole length of the body. Two of theſe are of vaſt ſize, and appear to ſerve as reſervoirs; for they ſend the air which they contain by tranſverſe branches into the other two ſmaller trunks, which proceed as uſual along the ſides of the body, and ſupply all parts with air-veſſels. Each of them produces a recurrent branch, which, after having croſſed the correſponding one, proceeds along the inteſtinal canal, and gives it an infinite number of ſmall ramifications. Cuvier thinks that the air contained in theſe different trunks follows a determinate courſe, relative to the occaſions of the parts to which it is diſtributed. The four trunks and the two recurrent branches are found in the perfect libellula; bnt they no longer derive their air from the anus. As the animal lives in the atmoſphere, its tracheæ are ſupplied from ſtigmata, near each of which is a veſicle, ſerving probably as a reſervoir. There is alſo a ſingle row of larger veſicles along the back.

The tracheæ appear to be deficient in ſome inſects, that is, in the arachnida, where we have ſtated that ſomething like a heart is perceptible. There is however a ſingle ſtigma at the baſis of the abdomen in the ſpider: but it leads only into a veſicle, from which no air-veſſels have been traced. Can this be the lung? and are there blood-veſſels diſtributed on its ſides?

Organs of the Voice.—By the voice we underſtand the ſound produced by animals in expelling air from their lungs, through the glottis: in this ſenſe it can be poſſeſſed by thoſe animals only which have lungs, as the mammalia, birds, and reptiles. Several inſects produce ſounds, and often very conſiderable ones, by the motions of various parts of their body: but there are no expreſs organs for this purpoſe. By theſe ſounds they invite each other, and expreſs their wants or their paſſions.

Organs of Generation.—Many very ſtriking peculiarities are obſerved in the propagation of inſects. The two ſexes of one and the ſame ſpecies are often ſo extremely unlike each other, that they would rather be taken for completely different ſpecies, than for animals that could pair together. Among the bees and other neighbouring ſpecies, the greateſt number of individuals have no ſex; they are conceived and born without being deſtined, as in the ordinary courſe, to conceive or produce impregnation. Their copulation is performed in a very extraordinary manner in many inſtances. The act is performed on the wing, and ſome are winged only during the ſhort ſeaſon of copulation. Several copulate only once, and the act is very ſoon followed by death: the life of the animal may be prolonged by deferring the copulation.

In ſeveral, as the cochineal inſect (coccus cacti), and the chigger (pulex penetrans), the pregnant female increaſes to an enormous ſize. The abdomen of the white ant (termes fatalis), when ready for laying, is calculated to be two thouſand times larger than it was before impregnation.

Organs of Generation in the Cruſtacea.—Theſe among the invertebral are what ſerpents and lizards are among the vertebral animals; their exterior organs are double; but, which is peculiar to themſelves, their internal organs, both teſticles and ovaries, are ſometimes united into one.

The decapoda in general have two peniſes and two vulvæ: the openings of the latter are found at the baſis of the third pair of feet. The two peniſes are quite at the back of the thorax, behind the fifth pair of feet: in this ſituation there is, on each ſide, a horny, pointed, tubular piece, opened longitudinally, which may be introduced into the vulva, and conducts the penis which paſſes through this tube. We ſee in the male, on the inſide, two very tortuous vaſa deferentia, each of which is continued to the root of the penis of its own ſide. In the lobſter and cray-fiſh the two canals proceed from a teſticle divided into ſix lobes, ſituated under the heart, behind the ſtomach, and between the two maſſes of hepatic veſſels. The teſtis is whitiſh, and has a glandular appearance. In the crabs the two canals are very large near the peniſes, become afterwards ſlender, and are ſo convoluted as to form the appearance of a gland on each ſide. Theſe glands are not united.

In the common lobſter the two ovaria are joined, ſo as to form a ſingle one to all appearance. The two oviducts are ſhort, ſtraight, and go directly to the vulvæ: the latter are ſimple holes pierced in the ſubſtance of the corſelet, near the third pair of feet in the crab, and in the very baſis of this third pair in the lobſter and hermit crab.

The female cruſtacea attach their eggs, after laying them, to the filaments of the fins under the tail, and carry them in that ſituation until they are hatched.

Organs of Generation in the proper Inſects.—The external parts are ſimple, and placed at the poſterior extremity of the body in moſt inſects. To this rule there are ſome exceptions, both in number and poſition. In the ſpiders they are double; and the male organs are placed on the maxillary palpi; the phalangia have a ſimple male organ, coming out from the root of the abdomen.

The libellulæ have the male organ at the baſis, and not at the point of the abdomen; and hence ariſes their very ſingular attitude in copulation. The male ſeizes the neck of the female with the hooks at the extremity of his abdomen, until the female bends herſelf back, and brings the extremity of her own abdomen to the baſis of that of the male.

The generative organs of the iuli are about the middle of the body.

I. *Male Organs.*—Theſe conſiſt in general of a penis with its coverings, of a common ſpermatic canal, and of two pairs of organs, which may be regarded as teſticles and veſiculæ ſeminales. Each of theſe pairs may be more or leſs ſubdivided; they vary in figure and in ſize.

1. *In the Coleoptera.*

a. In the Lamellicornia.—The genera ſeparated from the ſcarabæi of Linnæus, as the melolonthæ, cetoniæ, trichiæ, ſcarabæi, &c. have numerous globular teſticles and veſiculæ in the form of tubes, as ſlender as threads, and exceſſively long. In the ſcarabæus naſicornis, for example, the two veſiculæ ſeminales are more than twenty times the length of the body, and are convoluted into a packet or maſs, which it is not very difficult to unravel. Their tube is a little enlarged before it joins the common canal. On each ſide there are ſix teſticles of a ſmall ſize, and producing each an excretory tube more ſlender than a hair: theſe ſix ſmall tubes are united into one canal, which is joined to that of the oppoſite ſide preciſely at the point where the veſiculæ ſeminales are united. The common canal, reſulting from theſe four tubes, becomes large and muſcular, and then goes into a horny ſheath, terminated by a kind of pincers, between the laminæ of which the penis is placed. The latter is merely a ſmall cylindrical tube. It appears that the two branches of the pincer are introduced into the vulva, and then ſeparated ſo as to facilitate the entrance of the penis. Swammerdam has given a very accurate figure of theſe parts.

The melolontha reſembles the S. naſicornis.

The organs are more complicated in the cetonia: there are twelve teſticles on each ſide, and, beſides the filiform veſiculæ, which are probably thirty times as long as the body, there are two other ſhort and thick pairs; the ſhorteſt of the latter has its extremity forked. The canals of the three pairs of veſiculæ, as well as the canals of the two groups of teſticles, join together at the ſame point to conſtitute the common ſpermatic tube, which goes to the penis.

The trichiæ reſemble the cetoniæ.

The coprides, or dung beetles, and the lucani, or ſtag beetles, do not follow the ſame type: they have only one teſticle on each ſide, and this is a globular and compact maſs made up of the convolutions of a ſingle tube. Their veſiculæ ſeminales are alſo filiform, but not ſo long in proportion as thoſe of the ſcarabæi.

b. In the Carnivora.—The organs are very ſimple in the dytiſcus; there are two large veſiculæ of moderate length, very little convoluted; two globular teſticles covered by a yellowiſh matter, which may be removed; they are then eaſily unravelled into a ſingle, filiform, ſlender and long veſſel. The vas deferens is merely the continuation of this: it enters the veſicula a little before that joins the oppoſite tube to form the common ſpermatic canal.

c. In the Clavicornia.—The ſtructure of the hydrophilus is more complicated than that of the dytiſcus: it has two oval teſticles, each of which is formed by the convolutions of a ſingle veſſel. The vas deferens, which is as fine as a hair, ſwells into a ſmall oval veſicle where it ends in the common canal. The principal veſiculæ ſeminales are large, with ſtrong ſides, ſpirally convoluted, and terminating ſuddenly in a ſmall veſſel folded in zig-zag, and forming the appearance of another ſmaller teſticle. There are, moreover, two acceſſory veſiculæ, with thin ſides, each divided into three branches, and into ſome ſmall blind appendices. The common ſpermatic canal has a muſcular enlargement towards its middle, and becomes again ſuddenly ſmall to enter the penis. Theſe parts are figured by Swammerdam, but rather rudely.

The ſilpha atrata has two large oval teſticles, formed of an infinite number of ſmall ſhort veſſels, reſembling thoſe bruſhes of which the hairs project in every direction. The vas deferens is ſmall and ſhort. There are two pairs of veſiculæ, both cylindrical and tolerably large; one of them is folded in a ſerpentine manner round the inteſtine, and may be four or five times the length of the body: the other is much ſhorter. The common ſpermatic canal is cylindrical and ſhort. The penis is alſo cylindrical, covered with horny pieces, but has no pincer. An oval bladder, of which the uſe is unknown, but which reſembles in its poſition and figure the urinary bladder of the mammalia, is found at its internal baſis.

d. In the Filicornia.—The common ſpermatic canal is eight or ten times the length of the body in the blaps mortiſaga; four organs reſembling veſiculæ are connected to it at its origin. Two of theſe firſt make ſome very regular ſpiral turns, growing at the ſame time ſmaller; and then enlarge again and are irregularly folded. The two others have a zig-zag courſe, and are much ſhorter.

2. *In the Orthoptera.*—The grylli have two conſiderable oval teſticles attached to the back: they are covered by a yellow mucoſity, in which the tracheæ may be ſeen beautifully diſtributed. They are compoſed of ſmall ſhort veſſels, which make up a kind of bruſh. The vas deferens is folded in the form of an epididymis: a little before joining the oppoſite one, to form the common canal, it is enlarged, becauſe it receives two groups of veſiculæ. One of theſe contains more than ſixty, and the other above two hundred much ſmaller than the former. The four bundles fill nearly half the abdomen. Two ſmall oval veſicles are found at the very point of union of the two vaſa deferentia.

3. *In the Hemiptera.*—The water ſcorpion (nepa ſcorpioides) has two ſmall, ſhort, and cylindrical veſiculæ, two large vaſa deferentia convoluted like the epididymis, and divided at their origin, each into four ſmall teſticles, each of which is again prolonged into a very long filiform veſſel. Theſe eight veſſels are convoluted into a maſs.

4. *In the Lepidoptera.*—There are two different forms in this order: the bombyx pavonia will ſerve as an example of one, and the ſame has been imperfectly exhibited by Swammerdam and Malpighi in the ſilkworm moth (bombyx mori). The common ſpermatic canal is divided into two veſiculæ ſeminales, at firſt a little enlarged, and then prolonged in the form of tubes. They continue united to each other in half their length. The vaſa deferentia enter in a very ſlender form into the ſwellings of the veſiculæ. They gradually enlarge, and terminate on each ſide in a maſs, which may be regarded as a teſticle. Malpighi has repreſented the veſicles broken a little above the inſertion of the vaſa deferentia; and Swammerdam a little beyond this point. The teſticles are ſmaller in the pavonia than in the bombyx mori.

The ſecond form may be exemplified in the ſphinx euphorbiæ, and it is juſt the ſame as Swammerdam repreſents in the papilio urticæ. The common canal, much longer, is divided into two long and ſlender veſiculæ, each of which is joined by a vas deferens: but the two laſt, inſtead of having ſeparate teſticles, are united into a ſingle rounded maſs

The preceding are the ſpecies of inſects, in which Cuvier has hitherto obſerved the male organs: there are three others in Swammerdam, which agree with theſe in the principal points.

The bee, among the hymenoptera, has two large oval veſiculæ, two rounded teſticles, with long filiform vaſa deferentia. There are two ſhort and ſmall acceſſory veſiculæ: the common canal is enlarged before it enters the penis.

In the order diptera the ſtratyomys has two oval teſticles, formed, like thoſe of the ſilpha and gryllus, of ſmall veſſels; two vaſa deferentia, and two ſimple filiform veſiculæ. The common canal is of a middling ſize. In the fly, which lays in cheeſe, on the contrary, there is a very long common canal, very ſhort vaſa deferentia, and large oval veſiculæ divided into two lobes.

II. *Female Organs.*—Theſe are much more uniform than the male in the whole claſs. They conſiſt, in general, of a common oviduct, opening at the vulva, and divided at its origin into two branches, each of which is again divided into a certain number of conical tubes of various length. The ova are ſo arranged in the interior of theſe tubes, that the largeſt are the neareſt to the oviduct, and that the others gradually decreaſe in ſize to the point of the tube, where they are imperceptible. When the ova have been diſcharged, the tubes remain empty. They may be already diſcerned in the chryſalis, a little before the metamorphoſis. Secretory veſſels of various forms end in the oviduct, and depoſit in it fluids for covering the eggs or for forming a ſhell.

The ſcarabæus naſicornis has ſix oviferous tubes on each ſide, each containing five or ſix eggs: an oval veſicle and a ſmall but rather long veſſel end in the oviduct.

The carabi have ten or twelve tubes, and the dytiſci twelve or fifteen; the oviduct has a ſimple and ſmall bladder, which is prolonged further in the carabus.

In the ſilpha atrata there are ſeven or eight tubes, and each contains four eggs. The latter do not become large until they arrive in the branches of the oviduct, which are of conſiderable ſize.

The tubes are very numerous in the hydrophilus, and form two large branches; round the baſis of each of theſe are five long and large ſecretory veſſels containing a green liquor.

The butterflies have on each ſide four very long tubes, filled with a large number of eggs, and forming, particularly in the fruitful ſpecies, rows like ſtrings of beads, four or five times longer than the body. The common oviduct is ſo ſhort as to be ſcarcely perceptible; it receives one or two veſicles, and two long veſſels.

The grylli have on each ſide about thirty tubes, each of which does not contain more than three or four viſible eggs: they are united by the tracheæ, and by a mucous ſubſtance, into two oval maſſes. The common oviduct receives a veſicle and a long veſſel.

The bees have the two laſt mentioned parts: their rows of eggs are numerous on each ſide. Cuvier thinks that he can perceive very ſmall ones in the neuter bees, which would confirm the notion of their being imperfectly developed females.

In the ſilpha there are five, and in the notonecta ſix rows on each ſide.

The libellulæ have two very long branches; their tubes are ſhort, ſmall, and almoſt innumerable.

The various boring inſtruments which certain genera, as the gryllus, ichneumon, tenthredo, and cynips, employ for depoſiting their ova in ſuitable ſituations, may be arranged with the organs of the female ſex. But, as theſe parts are completely external, and have been well deſcribed by naturaliſts, we ſhall not ſay any thing more on the ſubject.

Spinning Inſtrument of the Caterpillars.—Almoſt all the caterpillars ſpin themſelves a covering, or at leaſt an attachment of ſome kind, before their metamorphoſis. The caterpillar of the bombyx mori is the moſt celebrated in this reſpect, ſince the thread compoſing its covering being abundant, flexible, brilliant, and eaſily wound off, forms the material from which our moſt ſplendid ſilks are formed. Other caterpillars, as that of the bombyx pavonia, form as large a quantity of ſilk, but it is hard, liable to break, and cannot be wound off.

The ſecretory organs producing the ſilk are the ſame in all caterpillars, excepting varieties in ſize, which is proportionate to the quantity of ſilk produced. Theſe, like all the other ſecreting organs of inſects, are two long tubes, commencing in a very ſlender and convoluted form; then growing larger to form a kind of reſervoir, and terminating in an excretory canal ſo ſmall that it can hardly be ſeen. The two canals terminate under the lower lip: and the animal draws out and elongates the ductile matter by moving its head from ſide to ſide.

Organs for producing Light.—Several animals of this claſs have the power of producing light; and the ſubſtance in which this property reſides is ſometimes diffuſed through the animal's body, ſometimes collected into a particular organ. The luminous matter muſt be regarded as an animal ſecretion produced like any other animal ſubſtance. A very full and intereſting account of this ſubject is contained in a paper by Mr. Macartney, in the Philoſophical Tranſactions for 1810, from which the following paſſages are extracted.

“ The power of emitting light has been obſerved in two animals of the cruſtaceous order, and ſeemed to reſide in the whole body. One of theſe, obſerved by ſir Joſeph Banks, in the paſſage from Madeira to Rio Janeiro, reſembled the common ſhrimp, but was leſs: it is named by Mr. Macartney cancer fulgens. The other was found in the Red ſea by captain Horſburg, appeared to be a monoculus, and to belong to the genus limulus of Müller. Mr. Macartney calls it limulus noctilucus. A third cruſtaceous animal of the genus lynceus of Müller, poſſeſſing luminous properties, has been ſeen off the coaſt of Malabar. Of other inſects ſome ſpecies yield light in the five following genera; *viz.* elater, lampyris, fulgora, pauſus, ſcolopendra;

dra. The only animals which appear to poſſeſs a diſtinct organization for the production of light are the four firſt of the laſt mentioned genera.

"The light of the lampyrides (glow-worm) is known to proceed from ſome of the laſt rings of the abdomen, which, when not illuminated, are of a pale yellow colour. Upon the internal ſurface of theſe rings there is ſpread a layer of a peculiar ſoft yellow ſubſtance, which has been compared to paſte, but by examination with a lens I found it organized like the common interſtitial ſubſtance of the inſect's body, except that it is of a cloſer texture, and a paler yellow colour. This ſubſtance does not entirely cover the inner ſurface of the rings, being more or leſs deficient along their edges, where it preſents an irregular waving outline. I have obſerved in the glow-worm, that it is abſorbed, and its place ſupplied by common interſtitial ſubſtance, after the ſeaſon for giving light is paſſed. The ſegments of the abdomen, behind which this ſubſtance is ſituated, are thin and tranſparent, in order to expoſe the internal illumination. The number of luminous rings varies in different ſpecies of lampyris, and as it would ſeem at different periods in the ſame individual. Beſides the luminous ſubſtance above deſcribed, I have diſcovered in the common glow-worm, on the inner ſide of the laſt abdominal ring, two bodies, which to the naked eye appear more minute than the head of the ſmalleſt pin. They are lodged in two ſlight depreſſions, formed in the ſhell of the ring, which is at theſe points particularly tranſparent. On examining theſe bodies under the microſcope, I found that they were ſacs containing a ſoft yellow ſubſtance, of a more cloſe and homogeneous texture than that which lines the inner ſurface of the rings. The membrane forming the ſacs appeared to be of two layers, each of which is compoſed of a tranſparent ſilvery fibre, in the ſame manner as the internal membrane of the reſpiratory tubes of inſects, except that in this caſe the fibre paſſes in a ſpiral inſtead of a circular direction. This membrane, although ſo delicately conſtructed, is ſo elaſtic as to preſerve its form, after the ſac is ruptured, and the contents diſcharged.

The light that proceeds from theſe ſacs is leſs under the controul of the inſect, than that of the luminous ſubſtance ſpread upon the rings: it is rarely ever extinguiſhed in the ſeaſon that the glow-worm gives light, even during the day; and when all the other rings are dark, theſe ſacs often ſhine brightly.

The organs for the production of light in the genus elater are ſituated in the corſelet; theſe likewiſe conſiſt of a peculiar yellow ſubſtance, placed behind tranſparent parts of the ſhell, which ſuffer the natural colour of this ſubſtance to be ſeen through them in the day, and when illuminated give paſſage to the light. On diſſecting the organs of light in the elater noctilucus, I found that there is a ſoft yellow ſubſtance of an oval figure lodged in the concavity of the yellow ſpots of the corſelet, which parts are particularly thin and tranſparent in this ſpecies. This ſubſtance is ſo remarkably cloſe in its texture, that, at firſt view, it appears like an inorganic maſs, but with a lens it is readily perceived to be compoſed of a great number of very minute parts or lobules cloſely preſſed together. Around theſe oval maſſes the interſtitial ſubſtance of the corſelet is arranged in a radiated manner, and the portion of the ſhell, that immediately covers the irradiated ſubſtance, is, in a certain degree, tranſparent, but leſs ſo than that which lies over the oval maſſes: it is therefore probable that the interſtitial ſubſtance in this ſituation may be endowed with the property of ſhining. In the elater ignitus the maſſes of luminous ſubſtance are extremely irregular in their figure; they are ſituated nearly at the poſterior angles of the corſelet, and are more looſe in their texture than the oval maſſes of the noctilucus, reſembling rather in compoſition the interſtitial ſubſtance which ſurrounds theſe maſſes in that ſpecies. The ſhell of the corſelet is ſomewhat thinner, and more tranſparent along both ſides of the margin, than at other places, but it is not, as in the noctilucus, elevated, and peculiarly clear and thin immediately over the ſeat of the luminous organ; conſequently the light emitted by the elater ignitus cannot be very brilliant."

In the fulgora candelaria and lanternaria, Mr. Macartney has found the hollow organ, from which the light proceeds, to communicate freely with the external air, by means of a chink or narrow aperture, placed on each ſide of the root of the proboſcis. This organ is lined by a membrane, between which and the horny part or ſhell there appears to be interpoſed a pale reddiſh ſoft ſubſtance, arranged in lines or ſtripes in the candelaria. It could not be determined, whether this furniſhes the light, or is the pigment, upon which the colour of the proboſcis depends.

The globes of the antennæ conſtitute the organs of light in the pauſus ſpherocerus.

"It is worthy of remark," ſays Mr. Macartney, "that in all the diſſections I have made of luminous inſects, I did not find that the organs of light were better or differently ſupplied with either nerves or air-tubes, than the other parts of the body. The power of emitting light likewiſe exiſts in many creatures, which want nerves, a circumſtance ſtrongly marking the difference between animal light and animal electricity." Swammerdan's Book of Nature, or Hiſtory of Inſects: Lyonet Traité Anatomique de la Chenille, qui rouge le bois de ſaule: Cuvier Leçons d'Anatomie comparée.

Insects *infeſting the human body*. The paraſitic animals, which are moſt commonly found inhabiting, and deriving their nutriment from, the internal cavities of the human body, are the three ſpecies of worms, which are denominated, by naturaliſts, *aſcaris*, *lumbricus*, and *tænia*; that is, the maw-worm, or thread-worm, round-worm, and tape-worm; to which may be added the *trichuris*, which is occaſionally ſeen. (See theſe words.) The external parts of the body, again, afford a nidus and ſuſtenance to one or two of the inſect tribes, eſpecially the *pediculi* of the head and of the *pubes*; the former of which are ſometimes bred in great numbers, and infeſt other parts of the ſurface, producing a loathſome and very obſtinate diſeaſe, the *morbus pedicularis*, or louſy diſeaſe. (See Phthiriasis and Prurigo.) It is not our object, however, to treat of theſe under the preſent article; but merely to notice briefly the occaſional exiſtence of various ſpecies of the *winged inſects*, in the different cavities of the human body, eſpecially in their firſt ſtate, that of *larva*, caterpillar, or grub; and to point out the manner in which they are probably introduced.

The medical writers of the ſixteenth and early part of the ſeventeenth century have recorded inſtances of various reptiles and other animals, which were diſlodged from their abode in different parts of the body, ſuch as frogs, lizards, ſerpents, &c.; which may be found on conſulting the collections of Borelli, Marcellus Donatus, Schenck, and others. But their credulity was at leaſt equal to their learning and induſtry, and ſubſequent obſervation has not confirmed their ſtatements, which probably originated from groſs ignorance of the economy of theſe creatures, or from wilful deception on the part of thoſe from whom they were ſaid to have been diſcharged. On the other hand, the microſcopic philoſophers not only peopled every organ of the body with worms and animalcules; but believed that all contagion conſiſted of the ſame beings, which, according to their nature, communicated ſcabies, and ſyphilis, ſmall-pox, dyſentery, the plague, and every other infectious diſorder. (See the learned diſſertation of Dan. Le Clerc, entitled "Hiſtoria Lator. Lumbricorum," p. 274, *et ſeq.*) But more accurate inveſtigation has likewiſe cauſed theſe notions to be exploded; and the catalogue of paraſitic creatures, which infeſt the human frame, in addition to the worms, &c. abovementioned, is reduced to a few varieties of the inſect tribes.

It is well known, that the internal cavities and paſſages of ſome animals, eſpecially the noſtrils and adjoining ſinuſes, the ſtomach, and *rectum* or ſtraight gut, in horſes, ſheep, and cows, are the ſituations in which alone certain inſects are apparently intended by nature to breed, and to be nurtured in their firſt ſtage of exiſtence. This is the caſe eſpecially with the ſeveral ſpecies of *œſtrus*, the grub or larva of which is called a *bott*. (See an ample hiſtory of this inſect, under the article Botts.) The *ova*, or eggs of theſe inſects are introduced into thoſe paſſages by the parent inſect, or are conveyed thither by licking with the tongue, inhaling odorous matters, &c. Now, although there does not appear to be any ſpecies of inſect deſtined particularly to be nurtured in the human body; yet it appears beyond all queſtion, that the larvæ of ſome of the winged inſects are occaſionally hatched and nurtured in the noſtrils and ſinuſes, as well as in the ſtomach and inteſtines of man.

The want of accurate inveſtigation, ſince the ſubject of entomology has been well underſtood, leaves us in a ſtate of uncertainty as to the number of inſects which are thus nurtured within the human body. It ſeems probable, however, as we might, perhaps, have anticipated, that the moſt frequent inſtances which occur, are thoſe of our moſt common domeſtic inſect, the varieties of *the fly*. The *larvæ* of ſeveral of the ſpecies of the fly (*muſca*, Linn.) are aquatic, or at leaſt inhabit moiſt and wet places, and therefore ſeem to be adapted to exiſt in the fluids of the human ſtomach: and the author of this article is in poſſeſſion of ſome larvæ of the common *houſe-fly*, the *muſca domeſtica minor* of Degeer (Hiſtoire des Inſectes, tom. v. tab. 2. fig. 4.), which were rejected alive from the ſtomach of a man by vomiting (ſee Edin. Med. and Surg. Journal, for Jan. 1811, p. 41.); and of others of the ſame fly, which were paſſed by ſtool by another perſon. The larva of another ſpecies of *fly* is alſo figured in the Journal, juſt referred to, by Dr. Cheyne, now of Dublin: and ſeveral examples of the larvæ of *flies*, diſcharged from the human inteſtines, are on record. Dr. Wahlbom, of Upſal, has related the caſe of a girl, who, after ſuffering conſiderable pain in the ſtomach and left ſide, diſcharged by ſtool a number of larvæ on ſeveral ſucceſſive days, after which ſhe was relieved from the complaint. "One of theſe larvæ, while it was kept in a phial, was converted into a *fly*, which proved to be the *muſca nigra* of Linnæus. (Faun. Suec. 1105.)" Dr. Wahlhom alſo ſtates, "that a few years ago there was a girl in Upſal, from whom a large quantity of worms were brought away, and theſe were *fly-worms*. N. Faun. Suec. 1064;" for an account of which he refers to Dr. Du Bois' Treatiſe de Tænia. (See Med. Chirurg. and Anatom. Caſes and Experiments, communicated to the Royal Academy of Sciences at Stockholm, tranſlated from the Swediſh, 1757, caſe 24.) Ruyſch has deſcribed and delineated both the larvæ, and the flies which originated from them, after they were diſcharged (it is affirmed) by urine, by a nobleman, in conſiderable quantities; and Tulpius has mentioned a ſimilar caſe, and has alſo figured the larvæ, which cloſely reſemble thoſe in the writer's poſſeſſion.

It muſt be acknowledged, however, that the bladder is the leaſt probable *nidus* for the larvæ of inſects, and we cannot readily conceive how they ſhould find their way into that cavity: while, on the other hand, miſtakes may be made upon ſuch a ſubject with the greateſt facility, as Valliſneri long ago remarked. Theſe larvæ might have crept or fallen into the utenſils, or the *ova* might have been depoſited there, and the larvæ afterwards obſerved in the urine. An inſtance of this kind of miſtake was related to the writer by an eminent ſurgeon. A lady was in great alarm, from the belief that ſhe frequently paſſed from the bowels ſeveral little red worms, extremely lively in their motions, which were found in the excretions. But it was ſtrongly ſuggeſted, that theſe worms muſt be inhabitants of the water-cloſet; and upon accurate examination, the ſuggeſtion was confirmed; they proved to be the larvæ of the *common gnat*, which are well known to be aquatic in their mode of life. In all caſes, therefore, it is neceſſary to be cautious in examining all the circumſtances, before it be concluded, that inſects, found in the excrementitious diſcharges, actually paſſed from the human body.

There is another ſpecies of inſect, which, in its ſtate of larva, or caterpillar, appears to be not unfrequently an inhabitant of the cavities of the human body, though not ſo commonly as the different ſpecies of fly; we mean the common *black beetle*, the *tenebrio molitor* of Linnæus. The grub of this inſect is a ſort of caterpillar, about an inch and a quarter in length, and equal to a large crow-quill in circumference, with ſix feet near the head, but deſtitute of feet at the other extremity: its body is divided into thirteen ſections. The introduction of this larva into the human body, or of the *ova* from which it is hatched, will be readily underſtood, when we mention that it lives principally in flour or meal; whence from the time of our oldeſt writer on inſects, Mouffet, it has been known by the appellation of the *meal-worm*. This writer has given a rude figure of the grub. (See his Inſectorum Theatrum, Lond. 1634, lib. ii. cap. 20. p. 254.) Two caſes, in which this meal-worm was diſcharged from the human body, have come to the knowledge of the writer of this article. (See Edin. Med. and Surg. Journal, above quoted.) Another is mentioned and figured by Dr. Kellie, of Leith, in the ſame Journal. And Tulpius has given a figure of the ſame larva, two of which, he ſays, were paſſed from the bladder of a woman of fifty years of age, and a ſimilar one from the noſe of another woman, who had previouſly ſuffered ſevere headache. (See his Obſerv. Med. lib. ii. cap. 51. tab. 7. fig. 3; and lib. iv. cap. 22.) The diſcharge of two from the bladder was probably inferred, by miſtake, from the grubs being found in the utenſil which received the urine: but the eſcape of the one from the noſe is probably correctly ſtated; for in this way the larvæ paſſed in one of the caſes, to which we have juſt alluded, and the noſe, or the adjoining cavities, are common receptacles for the ova or larvæ of other ſpecies of inſects, as we ſhall preſently ſhew. Foreſtus has recorded ſome caſes, in which the grubs were moſt probably of the ſame nature. He mentions the circumſtance, which he witneſſed, of a girl who rejected from the ſtomach two beetles, one at the interval of two days after the other, and likewiſe a living worm or grub, which was, in all probability, the grub of the beetle. He alſo mentions the ejection of a ſpecies of caterpillar, "vermem erucæ ſimilem," by vomiting, after which a ſevere pain of the ſtomach of conſiderable duration was removed. Foreſti Opera, lib. xxi. obſ. 25.

Several of the inſects above-mentioned were diſcharged from the noſe, in which cavity, in brute animals, the exiſtence of larvæ is very common, and the *ova* appear to be actually depoſited there by the parent inſect. Mr. Bracy Clark queſtions the exiſtence of human *botts* (*œſtrus hominis*); but that inſects of this ſpecies ſometimes find a *nidus* in the naſal paſſages of the human ſubject, is proved by a caſe, related by Dr. Heyſham, of Carliſle, in which three botts were diſcharged from the *antrum* of Highmore, or *ſinus* of the cheek of a woman, after that cavity had been perforated by a trocar. An intolerable hemicrania was occaſioned by their preſence, and ultimately proved fatal. (See Medical Communications, vol. i. art. xxx. and plate 1. figs. 2 and 3.) An example of a *centiped* lodging in the frontal *ſinus* is recorded in the Edin. Medical Eſſays, vol. v. p. 991. In tropical climates, as we learn from Dr. Lempriere, the maggots or *larvæ* of the large blue fly, which are conſtantly buzzing about the ſick, are generated in the noſe, mouth, and gums, in the laſt ſtages of fever, when the patients ſleep or doze with their mouths open, the nurſes finding great difficulty in preventing the depoſition of the *ova* in thoſe parts. This author mentions one inſtance, in the lady of an officer, who had eſcaped from the attack of fever, but in whom "theſe maggots were produced, which burrowed and found their way by the noſe through the *os cribriforme*, into the cavity of the cranium, and afterwards into the brain itſelf, to which ſhe owed her death." Lempriere, Obſ. on the Diſ. of the Army in Jamaica, vol. ii. p. 182.

It is probable that thoſe caſes on record, in which worms were ſaid to be coughed up from the lungs, were in reality inſtances of the larvæ of inſects, bred in the poſterior cavities of the noſe, and removed by the agitation of coughing into the throat, and thence expelled. See a caſe of this ſort, related by the late Dr. Percival, in his Med. Eſſays, vol. iii. p. 272, in which two maſſes of grumous blood were brought up by coughing, as large as a nutmeg, one of which, when opened, "was found to contain a conſiderable number of worms, like maggots, in a very lively ſtate."

Beſides the larvæ of *flies*, of the *black beetle*, and of the *œſtrus*, above-mentioned, ſcarcely any other inſects are deſcribed upon good authority, as being nurtured in the human body, if we except the *millepedes*, which are mentioned by ſome authors. It is impoſſible to ſay much on the ſubject of deſtroying theſe larvæ by medicine; ſince their exiſtence cannot be aſcertained before they are actually diſcharged and ſeen. The ſymptoms produced by the irritation which they excite, conſiſt only of ſevere pains in the parts where they happen to be, which of courſe cannot be diſtinguiſhed from pain occaſioned by other cauſes. If the exiſtence of the worms was known, or could be ſurmiſed, perhaps the internal exhibition of the oil of turpentine might be reſorted to with ſucceſs; for it appears that this liquor is poiſonous to all the inſect tribe, as well as to worms. Experience has now decidedly proved its efficacy in the deſtruction of the tape-worm. (See Edin. Med. and Surg. Journal, for April and July, 1810.) It has been uſed with ſucceſs in the way of glyſter in the caſe of aſcarides; and Dr. Lempriere found it ſerviceable when injected into the paſſages infeſted by maggots.

Insects, *Anatomical Uſe of.* The inſect-world affords us numerous uſes, and thoſe many of them ſuch as no one would at firſt thought imagine, and which no other operations or operators could ſo well effect. In the minutiæ of anatomy, where knives cannot be introduced, the maggot or the ant may be employed with great ſucceſs. Skeletons of fœtuſes have been prepared by burying them in an ant-hill, and that in ſo accurate and perfect a manner, that all who have ſeen them, have admired by what means they could be ſo nicely finiſhed; and the ſecret of the great Ruyſch, by which he cleared away the parenchymatous ſubſtance from his vaſcular preparations, was of this kind. After injecting the veſſels of any part with wax, all that remained to the completing of theſe preparations, was the taking off the parenchymatous or fleſhy matter from between and among them. Other anatomiſts of his time did this by the knife, or by maceration in water and other liquors; but it appeared a ſort of magic to them, that his were always not only much ſooner executed, but to a greater nicety and perfection than their's ever poſſibly could be. His method was only to put a number of the common fleſh-eating maggots to the ſubſtance; and theſe regularly eat away all the fleſh, their heads getting into crevices which no inſtrument could reach, and the whole ſubſtance of the injection remained unhurt, as their ſoft bodies could glide betwen its niceſt parts without injuring them; and the wax being no food for them, was in no danger of being eroded, even in its ſmalleſt pieces. The ſeveral ſizes of the worms or maggots bred from the eggs of different flies were of great uſe in the perfecting of the preparations; for while the larger ſort eat the more fleſhy parts, where the veſſels are large and but few in number, the middle-ſized maggots got into the interſtices of the more vaſcular parts, and the moſt minute of all, which are uſually alſo the moſt numerous, kept about the ſurface, and eat away between and among the capillary veſſels.

The maggots produced from flies are not the only animals fit for this kind of buſineſs. There are ſeveral ſpecies of beetles of the ſmaller kinds, whoſe eggs hatch into a ſix-legged worm, which eats as much and as nicely as the fly-maggots. All theſe may be employed very ſucceſsfully in the preparations of the parts of animals.

Theſe nice anatomiſts are not confined to animal ſubſtances; they often exert their power alſo on vegetables. Many of them feed on the leaves and fruits of plants; and ſome ſpecies of theſe work ſo nicely, that they eat away all the outer membrane and internal parenchymatous ſubſtance of the leaves, ſo as only to leave the net-like plexus of veſſels ſtanding. Yet theſe being unhurt ſhew the true figure of the leaf, and are a ſort of vegetable ſkeletons, but very poorly imitated by art in the common way, by long macerations in water; this method uſually deſtroying and waſhing away many of the ſmaller veſſels, which the tender mouths of theſe creatures ſpare. If they exert their ſkill often upon leaves in this manner, they do it alſo ſometimes with equal, if not greater, ſucceſs upon fruits. As in the leaves, thoſe which have the tendereſt parenchyma and the firmeſt ribs ſucceed beſt; ſo alſo it is in fruits. The leaves of the ruſcus or butcher's broom are often found thus beautifully anatomiſed; and of all fruits, none ſucceeds ſo well as that of the ſtramonium, or thorn-apple. Wherever this plant grows in any plenty, the fruit towards autumn, while it is yet full of juice, is attacked by a ſmall worm, which eats away all the parenchyma, and leaves every veſſel ſtanding in its place; and this not only in the outer coat of the fruit, but in the very inner cells of the ſeeds. Theſe veſſels remain exactly in the ſhape of the fruit, and, growing white with the air, exhibit the moſt elegant and beautiful ſkeletons imaginable, while yet ſtanding on the plant. The animal which effects this, is a hexapode worm produced from the egg of a ſmall beetle: and differs very little from ſome of thoſe which ſo elegantly eat away the fleſhy parts from the injected anatomical preparations. Theſe are gregarious animals like ſome ſpecies of the ſmaller caterpillars, and numbers of them are always at work together on the ſame leaf or fruit, ſo that the ſkeleton is ſoon made. They begin by piercing a number of little holes into the ſubſtance of the leaf, and thence burrow under the integument till they meet one another; and this being done all over the leaf, they leave it, and go to work upon another.

INSECTS, *Vegetable Diſeaſes of.* All ſuch vegetable affections or diſeaſes as are produced by different ſorts of animals of the inſect kind, are very numerous according to their nature and thoſe of the plants: but the chief inſects that affect plants of the fruit-tree kinds, are thoſe of the aphis, acarus, ant, chermes, cicada, coccus, earwig, papilio, phalæna, and thrips tribes.

And of the firſt ſort there are a vaſt number of ſpecies, each tree being ſaid to be infeſted by a different diſtinct ſpecies. Hence the author of the "Syſtema Vegetabilium" has denominated them from the trees on which they are found; as the cherry aphis, the currant aphis, the plum aphis, &c. The males are few in compariſon with the females, and have wings, while the latter are numerous and without them. See PUCERON, and VINE-FRETTER.

The ſecond is a highly deſtructive inſect in houſes where forcing is practiſed. It is not furniſhed with wings, but the female is oviparous. The ſpecies, as in the former caſe, are very numerous. It often commits great miſchief on vines, peaches, nectarines, cherries, forced kidney-beans, melons, &c. See *Red* SPIDER.

And the third, or ant, is highly injurious to fruits, eſpecially thoſe of the peach kind, as they become in a ſtate of maturity. They run all over the trees, and the beſt fruit is occaſionally filled with them. It has been ſuppoſed by ſome that they are of uſe by devouring the alphides on the trees; but Mr. Forſyth is of a different opinion, and we have ſeen fruit much ſpoiled by them in various inſtances.

The beſt method of deſtroying them, according to the above author, is, by making holes in the ground along the ſide of the wall where the fruit-trees are, by an iron crow, ſo that the inſide ſurface may be quite ſmooth. Theſe inſects, from being diſturbed, ſoon come to the holes, and fall into them; when, being prevented from getting up by the ſmoothneſs of the ſides, they may be readily deſtroyed by pouring water upon them. But more effectual methods are, either by mixing quick-lime with ſoot, and placing it on their tracks, or putting it in their neſts, and then pouring water, or urine and ſoap-ſuds, upon it, ſo as to ſlack it, confining the heat by a turf or ſome earth. The heat thus produced ſoon deſtroys them. The powder of ſtaveſacre, laid round the ſtems of the trees, is ſaid to prevent their running upon them and thereby becoming injurious.

The fourth, or chermes, belongs to the order hemiptera; and there are ſeveral ſpecies. Their ſpecific names are taken from the different plants on which they are generally met with: as the chermes graminis, or graſs bug; chermes ficus, or fig-tree bug, &c. The laſt is one of the largeſt of the genus, being brown above and greeniſh beneath, and has four long wings, placed in the form of an acute roof. The *larva* is of an oblong form, and has ſix feet, but its motion is ſlow. When attempted to be caught, the chermes makes its eſcape rather by leaping than flying, by means of its hinder legs, which play like ſprings. Several of the ſpecies are provided at the extremity of their bodies with ſmall ſharp-pointed implements, but which lie concealed; and theſe they draw out in order to depoſit their eggs, by making punctures in the plants that ſuit them. It is in this way that the fir tree chermes produces that enormous ſcaly protuberance which is ſometimes found at the ſummit of the branches, and which is formed by the extravaſation of the juices occaſioned by the punctures. The young larvæ ſhelter themſelves in cells contained in the tumour. Theſe inſects are capable of being deſtroyed in the ſame manner as the cocci tribe.

The fifth, or cicada, belongs to the ſame order as above, and the larvæ of many of this tribe void large quantities of frothy matter upon the leaves and branches of the plants and trees, in the midſt of which they are always concealed, probably for protection, and to be ſhaded from the ſame influence. Theſe inſects ſhould be deſtroyed, as the froth is unpleaſant, and the leaves of the trees are often devoured, by rubbing off the larvæ with the hand, and afterwards watering the trees well with ſoft water, ſuch as that of ponds or other expoſed ſituations.

The ſixth, or coccus, alſo belongs to the ſame order, and the males have wings, but the females none. It may be noticed, that the ſorts moſt commonly met with when full grown, have ſomewhat the form of a boat with the keel uppermoſt, being apparently without feet, eyes, &c. while in this ſtate reſembling ſome ſorts of galls or excreſcences of the bark of trees or other plants.

It has been obſerved by Mr. Forſyth, that a "thin film, of a white cotton-like ſubſtance, is interpoſed between the flat part of the body and the tree. This is common, in a greater or leſſer quantity, to all the ſpecies, and appears at firſt all round the edge as a kind of cement, to join it to the tree. The males are very few in proportion to the females, and not nearly one-fourth of their ſize; they are beautiful little flies, which, after a ſhort but active life, terminate their exiſtence without having taſted food, being provided with no ſort of organs for that purpoſe."

It is likewiſe remarked, "that the peach, nectarine, and pear-tree, are very much infeſted with theſe inſects: they frequently cut through the bark, and the trees then appear as if they had been ſcratched by cats." He has "ſeen ſome with this appearance all over them."

It is adviſed, that, "when theſe inſects firſt appear on the bark, they ſhould be ſcraped off with a wooden knife, and the ſtem and branches of the tree well waſhed with ſoap-ſuds and urine, applied with a ſtiff painter's bruſh. This ſhould be done in February before the buds begin to come out. But if the outer bark is perforated, it muſt be cut or ſcraped off with a long knife; and if you find any brown ſpots in the inner bark, they muſt be carefully cut out. This diſeaſe is, it is ſuppoſed, one great cauſe of the canker, and of the death of the tree."

And it is added, that "when this diſeaſe has made its way through both barks, as is often the caſe, the branches on each ſide of the tree may be cut cloſe to the ſtem, if it has an upright one; but if the tree be trained fan-faſhion, the beſt way is to head it near to the place where it was grafted." He ſtates, that he has "headed old pear-trees which were ſo dead, except a ſmall ſtrip of live bark on one ſide, that you might rub the bark off them as eaſily as off a bundle of faggot-ſticks that had been cut upwards of a year; yet theſe trees have ſhot out freſh branches to the length of ſeventeen feet in two years, and produced fine fruit the ſecond year." It is adviſed to apply the compoſition immediately after heading or cutting, or paring off the diſeaſed bark. See COMPOSITION.

It is further remarked, that "a very deſtructive ſpecies of the coccus tribe has done incredible damage to the apple-trees in the nurſeries and gardens in the neighbourhood of London. Some nurſerymen have loſt ſeveral thouſand apple-trees in one year. Theſe inſects attach themſelves to their bark by their ſuckers, and by feeding on the juices of the tree, rob it of its nouriſhment. Such trees as are infeſted with them have a ſickly appearance. Theſe inſects generally make their neſts where branches have been cut off, or in hollow places, where the canker has eaten holes in the trees. Their firſt appearance is like a white down; on touching or rubbing them they tinge the fingers of a crimſon colour, like cochineal. If ſuffered to remain long on the trees, they take wing, like aphides."

It is ſtated, by the ſame author, that the method that has been followed for theſe ten years to deſtroy them, is to "rub the places where their neſts are with an old bruſh, ſuch as painters uſe, till they are all cleaned off; and if the part be canker-eaten, to cut it clean out with a knife or chiſſel; he then takes of ſoap-ſuds and urine equal parts, and with this he waſhes the wound and the bark all round it; and with a bruſh applies the compoſition, mixed with wood-aſhes and the powder of burnt bones, covering the wound all over with it. Afterwards he ſhakes ſome of the powder of wood-aſhes and burnt bones, mixed with an eighth part of unſlacked lime finely powdered and ſifted over the hollows, or where knobs have been cut off."

And it is adviſed, that "at the ſame time that the trees are cleared of the cocci, the caterpillars ſhould be picked off."

The writer remarks, that "the firſt time that he obſerved the new coccus which has done ſo much miſchief to the apple-trees about London, was in a garden of his own at Chelſea, about the year 1782 or 3; and as far as he can learn, they were imported among ſome apple-trees, by the late Mr. Swinton of Sloane-ſtreet. Mr. Swinton afterwards removed his nurſery to the King's Road near Chelſea college, which now goes by the name of the Foreign Nurſery."

By ſome, train oil has been tried, laid on with a painter's bruſh, but without effect.

The ſeventh ſort, or earwig, is often very deſtructive to fruit, particularly that of the peach kind. The method recommended by Mr. Forſyth for deſtroying them, and which he has long purſued with ſucceſs, is to "take old bean-ſtalks, and cut them about nine inches long, tying them up in ſmall bundles with ſome pack-thread, or with ſmall yellow willows, and hanging them on nails againſt the wall, at different parts of the trees. The firſt thing in the morning, being provided with a board about eighteen inches ſquare, and a ſmall wooden trowel, take down the bundles of bean-ſtalks one by one, ſtrike them againſt the board, and with your trowel kill the earwigs as they fall out of the ſtalks. If you follow this up every morning, (or every other morning,) you will be able to keep them under," without much difficulty.

It is ſuggeſted, that this method anſwers for any ſort of trees infeſted with earwigs. In ſome years the writer has "ſeen a great part of the fruits, eſpecially the ſmooth-ſkinned ſorts, deſtroyed by theſe inſects, and a ſmall green caterpillar; and in a ſcarce year of fruit, the leaves of peaches are frequently deſtroyed by them." It is adviſed, that "the ſhreds taken from trees that have been unnailed in autumn, ſhould be ſoaked in boiling hot ſoap-ſuds for three or four days previous to their being uſed again; as this will kill the eggs of earwigs and other inſects that may be depoſited on them."

The eighth, the papilio or butterfly ſort, belongs to the order lepidoptera.

There are a great many ſpecies of this genus, moſtly diſtinguiſhed by the colour of their wings. The more common ſorts, with their caterpillars, are well known; and Mr. Forſyth adviſes, that the caterpillars and chryſalides ſhould be carefully picked off, and the trees well watered with clear lime-water and tobacco-water mixed well together. The ninth, the phalæna or moth kind, are extremely numerous, their caterpillars differing much in ſize, ſhape, and colour. After caſting their ſlough ſeveral times, all of them ſpin their cod, in which they are transformed to chryſalides. In this ſtate they are often found rolled up in the leaves of fruit trees, eſpecially thoſe of the pear, plum, and cherry kinds. See PHALÆNA.

And of the ſphinx, or hawk moth kind, there are a vaſt number of ſpecies. Their caterpillars apply the hinder parts of their bodies to the branches of the trees, holding the reſt erect; hence the name. But in general they ſpin their cod under ground. They appear early in the morning, or after ſun ſet, flying heavily, and making a ſort of noiſe. Several of the caterpillars are green, and ſome brown, yellow, ſpotted, or belted.

The phalæna nuſtria, or lackey moth, depoſits its eggs in rings or circles round the branches of fruit trees, having the appearance of a necklace. See PHALÆNA.

The tenth ſort, or thrips, belongs to the order hemiptera, and there are ſeveral ſpecies. It is extremely ſmall, ſo as ſcarcely to be diſcovered. This inſect produces great miſchief on fruit trees, devouring the fruit as well as the leaves. It is capable of being deſtroyed in a ſimilar manner to that of the cocci.

But the nature of the various effects of theſe different inſects, and the means of removing them, will be more fully conſidered and explained, in deſcribing the ſeveral vegetable diſeaſes that are produced by the attacks of different ſorts of animals of this kind. See VEGETABLE *Diſeaſes*.

INSECTS, *Petrified*, in *Natural Hiſtory*. The works of the earlier writers on extraneous foſſils, contain accounts of various inſects ſaid to be found in the earth. Mr. William Martin, a late and correct writer on this ſubject, ſeems, however, to doubt, whether the remains of any of the winged tribe of inſects have been found enveloped in the ſtrata; although ſuch inſects in a perfect and natural ſtate of preſervation are very common in pieces of amber. The limeſtone of Oening is ſaid by M. Werner to produce ſpecimens of the larvæ of the libellula or dragon-fly, and of the nepa or water-ſcorpion. Inſects without wings, of the cancer, monoculus, and oniſcus genera, are not uncommon in ſome ſtrata. In his "Petrificata Derbienſia," Mr. Martin deſcribes and figures (tab. 45.) an inſect found in the ſhale limeſtone of Aſhford and Bakewell Moor, which he calls the Derbyſhire oniſcite, and expreſſes an opinion, which ſeems pretty well founded, that it differs eſſentially from the oniſcite of the Dudley and Coalbrook-dale lime quarries. He alſo figures and deſcribes a lunated monoculite, ſaid to be found in iron-ſtone, near Mansfield, in Nottinghamſhire, but this probably is a miſtake, particularly if others of the ſame kind were found near Cheſterfield in Derbyſhire. The late ingenious Dr. Woodward had perſuaded himſelf, that all the many flies and inſects preſerved in amber, were of the vernal tribes, and concurred with other foſſil ſubjects in proving, that the Moſaic deluge happened in the ſpring ſeaſon of the year: later and more correct obſervations ſeem, however, to prove, that all the organic remains of the ſtrata, and even moſt of thoſe of the alluvia, cannot have relation to that event, ſince they differ eſſentially from the recent inſects, animals, &c. to which they have a reſemblance, and all ſuch ſeem rather to have been created and lived, during the ſucceſſive creation and depoſition of the mineral ſubſtances, compoſing the ſtrata in which they are imbedded, and long prior to the creation of the preſent race of animals and vegetables, of whoſe origin Moſes has given us ſo ſuccinct and ſatisfactory an account, as according with the preſent appearances of nature.

INSERTED COLUMN. See COLUMN.

INSERTION, a term frequently uſed, in *Anatomy*, to ſignify the implication of one part within another.

The inſertion of the bones, muſcles, and nerves in the members of an animal, is exceeding artful: the vena cava has its inſertion in the right ventricle of the heart.

INSERTION is alſo uſed, in *Agriculture*, for the incloſing a graft within the cleft of a tree. See GRAFTING.

INSESSUS, or INSESSIO, in *Medicine*, a kind of half-bath or ſemicupium, uſually prepared with a decoction of ſeveral herbs proper for the lower parts, wherein the patient ſits down to the navel.

It has ſeveral uſes; as the eaſing of pain, ſoftening the parts, diſpelling a flatulent matter, and frequently promoting the menſes.

INSHILLA, in *Geography*, a town of Africa, near the E. coaſt of Tunis; 108 miles S. of Tunis.

INSIDE GUARD, in *Fencing*, a guard with the broad-ſword, to ſecure the face and front of the body from a cut made at the inſide of the poſition, above the wriſt. See GUARD.

INSINUATION denotes a cunning, and covert way of creeping into any perſon's favour.

INSINUATION *of a will*, among *Civilians*, is the firſt production of it, or the leaving it with the regiſter, in order to its probate. See WILL.

INSIPID, TASTELESS, that which has nothing in it pungent enough to affect the palate, tongue, &c. and to occaſion that ſenſation we call *taſting*.

INSITION, INSITIO, in *Botany*, denotes the ſame with engrafting; *viz.* the act of inſerting and uniting a cion, bud, or the like, in the ſubſtance of the ſtock.

INSOKO, in *Geography*, a town of Africa, on the Gold Coaſt; 120 miles from the ſea.

INSOLATION, in *Medicine*, from *in* and *ſol*, the *ſun*, a term uſed by ſome writers to expreſs the diſeaſe, occaſioned by the direct action of the ſun's rays upon the human body, which has been called, in the Latin and French languages, *ictus ſolis*, and *coup de ſoleil*. See an account of this diſorder under the head HEAT, *in Medicine*.

INSOLATION, in *Pharmacy*, a method of preparing certain fruits, drugs, &c. by expoſing them to the heat of the ſun's rays; either to dry, to maturate, or to ſharpen them, as is done in vinegar, figs, &c.

The word comes from the Latin verb *inſolare*, which is uſed by Pliny and Columella; and ſignifies *to expoſe to the ſun*.

INSOLVENCY, *Act of*, in *Law*, an occaſional act, frequently paſſed by the legiſlature; whereby all perſons whatſoever, who are either in too low a way of dealing to become bankrupts, or not being in a mercantile ſtate of life are not included within the laws of bankruptcy, are diſcharged from all ſuits and impriſonment, upon delivering up all their eſtate and effects to their creditors upon oath, at the ſeſſions or aſſizes; in which caſe their perjury or fraud is uſually, as in caſe of bankrupts, puniſhed with death.

INSOLVENT, a term applied to ſuch perſons as have not wherewithal to pay their juſt debts.

A perſon dying, and not leaving eſtate ſufficient to diſcharge theſe, is ſaid to die inſolvent.

INSPECTING *Field-officer of a Diſtrict*, in *Military Language*, denotes an officer, ſelected from the line, and nominated by the War-office, to ſuperintend and to vouch for the faithful diſtribution of monies which are iſſued to officers acting on detachment, or on recruiting parties, within the limits of his ſtation.

All diſtrict pay-maſters are ſtrictly enjoined by the laſt general regulations to get their muſter-rolls and pay-liſts duly authenticated, not only before a juſtice of the peace, but to have them witneſſed by the inſpecting field officer. All the recruiting officers, &c. within the limits of the diſtrict are accountable and ſubordinate to the inſpecting field officer. It is the duty of the latter to be particularly minute in his examination of every thing which appertains to the recruiting ſervice. They have the command of all recruiting parties of regiments of cavalry and infantry in their diſtricts; they are authorized to give an intermediate approval of the recruits whom they judge fit for ſervice, except in caſes where regiments are ſo quartered, as to render it, in point of diſtance, equally convenient for the recruits to be ſent to their own head quarters. The ſenior officer in each quarter is ordered to report to the field officer of the diſtrict. No officer is to leave his ſtation even for one day, without reporting to the field officer who has the command of the recruiting parties in the diſtrict, or to be abſent from it for more than one day, without the previous permiſſion of the field officer. The field officers in their diſtricts, are to be reſponſible for the dreſs, regularity, and good conduct of the officers, non-commiſſioned officers and pivate men of the ſeveral recruiting parties under their command. They are conſtantly to wear their uniforms, whilſt in their diſtricts, and they are to ſee, that his majeſty's orders reſpecting the due obſervance of diſcipline, regularity, and uniformity of appearance among the officers, non-commiſſioned officers and privates, be ſtrictly and unequivocally adhered to.

Field officers of diſtricts may order detachment courts martial, to be compoſed of the recruiting officers in their diſtricts, in the uſual number and ranks, and they are to approve of every ſuch court martial, and to direct the puniſhment awarded thereby to be executed, mitigated or remitted, as they ſhall think expedient. They are to receive orders from the inſpector-general of the recruiting ſervice, reſpecting the nature of their returns; and all returns and reports are to come to the inſpector-general through them. Each diſtrict field officer has an allowance of ten ſhillings a day, in addition to the full pay of his reſpective regimental rank, and he is to be reimburſed for the actual expence he incurs for ſtationary and poſtage of letters; which charge muſt be accompanied by a certificate upon honour.

Each diſtrict field officer is allowed to appoint a ſubaltern officer (not employed upon the recruiting ſervice) to act as adjutant in the diſtrict. The pay or allowance of ſuch ſubaltern is three ſhillings a day in addition to his full regimental pay; he is alſo authorized to nominate two ſerjeants, with the additional pay of ſixpence each, one to act as ſerjeant major, and the other as clerk to the diſtrict.

Each field officer may moreover give directions to the hoſpital mate, who is placed under his orders, to examine the recruits when brought for inſpection, and to give ſuch medical aſſiſtance as may be in his power, to the ſeveral recruiting parties in the diſtrict he belongs to.

When colonels of regiments take upon themſelves the whole direction of the recruiting ſervice for their own corps, they muſt conform to the regulations which require returns to be made to the inſpector-general of the recruiting ſervice; and they muſt inſtruct their officers to ſend weekly returns to the regulating field officer, in whoſe diſtrict they are ſtationed, of all the caſualties that have occurred. See pages 105, 106, 107, and 108 of the General Regulations.

INSPECTION denotes examination, ſurvey, and ſuperintendance of *general*, *regimental*, and *company* duties. A *general* inſpection is made annually by the reviewing generals of diſtricts. Every regiment, on this occaſion, is minutely looked into, and a faithful account muſt be delivered by each commanding officer of the actual ſtate of his regiment, together with all the caſualties that have occurred during the current year. The inferior economy of the corps is not only inveſtigated to the bottom, but the diſcipline of the men is likewiſe examined. For a more particular explanation of the latter, ſee Review.

Inspection, *Regimental*, is made once a month by the commanding officer. The clothing, the neceſſaries, arms, and accoutrements belonging to the different companies are examined by the lieutenant-colonel or major of the corps. Specific returns are made by the officers commanding troops or companies, by whom the debts and credits of the men, which have been made up and accounted for on the 24th day in each month, in infantry regiments, and on the 24th day in each ſecond month in cavalry corps, are exhibited for examination at head quarters. This forms the ground-work or baſis of the general inſpection, at which the troop or company book ſhould always be produced.

Inspection, *Private, of Companies*, is the firſt ſtep towards the other two, and ought to be made every Monday morning, by each officer commanding a troop or company, or by his ſubaltern.

Inspection *of Neceſſaries* is an examination of the different articles which every ſoldier is directed to have in good repair. The regular or eſtabliſhed proportion of neceſſaries that each ſoldier of cavalry and infantry is to be in poſſeſſion of on the 24th day of each month, to entitle him to receive the balance that may be then due to him, conſiſts of the following articles.

Cavalry.—3 ſhirts, 2 pair of ſhoes, 3 pair of ſtockings, 1 pair of gaiters, 1 forage cap, 1 ſaddle-bag, 1 pair of canvas, or woollen over-hoſe, 1 canvas, or woollen frock or jacket, 1 ſtock, 1 black-ball, 2 bruſhes, 1 curry-comb and bruſh, 1 mane comb and ſpunge, and 1 horſe-picker.

Infantry.—3 ſhirts, 2 pair of ſhoes, 2 pair of ſtockings, or 2 pair of ſocks, 1 pair of long gaiters, 1 forage cap, 1 pack, 1 ſtock, 1 black-ball, and 2 bruſhes.

Inspection, or *Examination, Trial by.* See Examination.

INSPECTOR-*General of Cavalry*, a general officer, whoſe particular duty is to inſpect all cavalry regiments, to report the ſtate of the horſes, and to receive ſpecific accounts from the different corps of their actual ſtate; he communicates with the commander-in-chief, and whenever a cavalry regiment is ordered to be diſbanded, it muſt be looked at by the inſpector-general before it is finally broken.

Inspector-*General of the Recruiting Service*, an officer of rank, through whom the field officers of diſtricts, and colonels of regiments (when they perſonally manage the recruiting ſervice of their own corps) tranſmit their ſeveral returns to the adjutant-general's office. All recruiting parties which are ſent to the great manufacturing towns in England and Wales, as alſo to Scotland and Ireland, muſt be previouſly authorized ſo to do by the inſpector-general.

Two field officers have been lately appointed as permanent inſpectors of *clothing*. Theſe inſpectors, or the inſpectors for the time being, are directed to view and compare with the ſealed patterns, the clothing of the ſeveral regiments of cavalry and infantry, as ſoon as the ſame ſhall have been prepared by the reſpective clothiers; and if the ſaid clothing appear to be conformable to the ſealed patterns, they are authorized to grant two certificates of their view and approval thereof; one of which certificates is to be delivered to the clothier, to be ſent with the clothing to the head quarters of the corps, and the other to be lodged with the general clothing board, as the neceſſary voucher for paſſing the aſſignment of the allowance for the ſaid clothing.

All clothing muſt be viewed, and certificates be ſigned by *both* inſpectors, except in caſes where the abſence of one of them ſhall be unavoidable; in all which caſes the cauſe of ſuch abſence is to be ſtated by the other inſpector, in his certificate of the view of the clothing.

Inſpectors of clothing are to follow all inſtructions which may be tranſmitted to them from the commander-in-chief, the ſecretary at war, or the clothing board.

Inspector *of Hoſpitals*, the next on the ſtaff to the ſurgeon general.

Inspector, a perſon to whom the care and conduct of any work is committed.

Inspectors, in the *Roman Law*, were ſuch perſons as examined the quality and value of lands and effects, in order to the adjuſting or proportioning taxes and impoſitions to every man's eſtate.

The Jews alſo have an officer, in their ſynagogue, whom they call *inſpector*, חזן, *hhazen*. His buſineſs conſiſts principally in inſpecting, or overlooking the prayers and leſſons, in preparing and ſhewing them to the reader, and in ſtanding by him to ſee he reads right; and, if he makes miſtakes, he is to correct him.

INSPICIENDO Ventre. See Ventre.

INSPIRATION, in *Phyſiology*, the act of drawing the atmoſpheric air into the lungs. See Lung.

Inspiration, among *Divines*, &c. implies the conveying of certain extraordinary and ſupernatural notices, or motions, into the ſoul: or, it denotes any ſupernatural influence of God upon the mind of a rational creature, whereby he is formed to any degree of intellectual improvements, to which he could not, or would not, in fact, have attained in his preſent circumſtances, in a natural way.

If a man were inſtantaneouſly enabled to ſpeak a language which he had never learned, how poſſible ſoever it might have been for him to have obtained an equal readineſs in it by degrees, few would ſcruple to ſay, that he owed his acquaintance with it to divine inſpiration. Or, if he gave a true and exact account of what was doing at a diſtance, if he publiſhed a particular relation of what he neither ſaw nor heard, as ſome of the prophets did, all the world would own (if the affair were too complex, and the account too circumſtantial to be the reſult of a lucky gueſs), that he muſt be inſpired with the knowledge of it; though another account, equally exact, given by a perſon on the ſpot, would be aſcribed to no inſpiration at all.

Thus the prophets are ſaid to have ſpoken by divine inſpiration.

Some authors reduce the inſpiration of the ſacred writers to a particular care of Providence, which prevented any thing they had ſaid from failing, or coming to nought; maintaining, that they never were really inſpired, either with knowledge, or expreſſion.

According to M. Simon, inſpiration is no more than a direction of the Holy Spirit, which never permitted the ſacred writers to be miſtaken.

It is a common opinion, that the inſpiration of the Holy Spirit regards only the matter, not the ſtyle, or words; and this ſeems to fall in with M. Simon's doctrine of direction.

Theological writers have enumerated ſeveral kinds of inſpiration: ſuch as an inſpiration of *ſuperintendency*, in which God does ſo influence and direct the mind of any perſon, as to keep him more ſecure from error in ſome various and complex diſcourſe, than he would have been merely by the uſe of his natural faculties; *plenary ſuperintendent* inſpiration, which excludes any mixture of error at all from the performance ſo ſuperintended; inſpiration *of elevation*, where the faculties act in a regular, and, as it ſeems, in a common manner, yet are raiſed to an extraordinary degree, ſo that the compoſer ſhall, upon the whole, have more of the true ſublime, or pathetic, than natural genius could have given; and inſpiration *of ſuggeſtion* when the uſe of the faculties is ſuperſeded, and God does, as it were, ſpeak directly to the mind, making ſuch diſcoveries to it as it could not otherwiſe have obtained, and dictating the very words in which ſuch diſcoveries are to be communicated, if they are deſigned as a meſſage to others. It is generally allowed that the New Teſtament was written by a ſuperintendent inſpiration: for without this the diſcourſes and doctrines of Chriſt could not have been faithfully recorded by the evangeliſts and apoſtles; nor could they have aſſumed the authority of ſpeaking the words of Chriſt, and evinced this authority by the actual exerciſe of miraculous powers: and beſides, the ſacred writings bear many obvious internal marks of their divine original, in the excellence of their doctrines, the ſpirituality and elevation of their deſign, the majeſty and ſimplicity of their ſtyle, the agreement of their various parts, and their efficacy on mankind; to which may be added, that there has been in the Chriſtian church, from its earlieſt ages, a conſtant tradition, that the ſacred books were written by the extraordinary aſſiſtance of the ſpirit, which muſt at leaſt amount to ſuperintendent inſpiration. But it has been controverted whether this inſpiration extended to every minute circumſtance in their writings, ſo as to be in the moſt abſolute ſenſe plenary. Jerom, Grotius, Eraſmus, Epiſcopius, and many others, maintain that it was not; whilſt others contend, that the emphatical manner in which our Lord ſpeaks of the agency of the ſpirit upon them, and in which they themſelves ſpeak of their own writings, will juſtify our believing that their inſpiration was plenary, unleſs there be very convincing evidence brought on the other ſide to prove that it was not: and if we allow, it is ſaid, that there were ſome errors in the New Teſtament, as it came from the hands of the apoſtles, there may be great danger of ſubverting the main purpoſe and deſign of it; ſince there will be endleſs room to debate the importance both of facts and doctrines.

What has been above denominated *ſuperintendent* inſpiration in the language of Dr. Doddridge, Mr. Whitby expreſſes by inſpiration of *direction*: and he thus diſtinguiſhes it from the inſpiration by *ſuggeſtion*. 1. Where there is no antecedent idea or knowledge of the things written for the good of others, to be obtained from reaſon or a former revelation, an inſpiration of ſuggeſtion muſt be vouchſafed to the apoſtles, in order to enable them to make ſuch things known to the world. But where there is ſuch an antecedent knowledge of the things to be indited, it can only be neceſſary that God ſhould immediately, or by ſome ſpecial occaſions, excite them to indite thoſe things, and ſhould ſo carefully preſide over and direct their minds, whilſt writing, as to ſuggeſt or to bring into their memories ſuch things as his wiſdom thought fit to be written, and ſhould not ſuffer them to err in the delivery of what was thus written in his name, or as apoſtles of God the Father and our Lord Jeſus Chriſt. 2. In all their revelations of myſteries, or things which could not otherwiſe be made known to them, either by natural reaſon or antecedent revelation, they muſt be acknowledged to have had them by an immediate ſuggeſtion of the holy ſpirit. 3. As for thoſe things which they did know already, either by natural reaſon, education, or antecedent revelation, they needed only ſuch an aſſiſtance or direction in them, as would ſecure them from error in their reaſonings, or in the confirmation of their doctrines by paſſages contained in the Old Teſtament; and therefore a continual ſuggeſtion muſt be neceſſary in this caſe. 4. In writing the hiſtorical parts of the Old Teſtament, or matters of fact relating to themſelves and others, it is only neceſſary, that what is there delivered as matter of fact ſhould be truly performed, as it is ſaid to have been done; but it is not neceſſary that they ſhould be related in that order of time in which they were performed, unleſs alſo that be affirmed of them: for this muſt be ſufficient to aſſure us of the truth of what they thus delivered. Moreover, in writing the diſcourſes contained in theſe books, it is not neceſſary that the very words ſhould be ſuggeſted or recorded, in which they were firſt ſpoken, but only that the true intent and meaning of them ſhould be related, though in diverſity of words; though the promiſe made to the apoſtles by our Lord, that the holy ſpirit ſhould bring to their remembrance all things which he had ſaid unto them, doth fairly plead for this exactneſs in what they have delivered of our Saviour's ſermons; it being ſcarcely imaginable their memory, without divine aſſiſtance, ſhould exactly give us all that was ſpoken in ſuch long diſcourſes. Laſtly, it appears, ſays Dr. Whitby, that I contend only for ſuch an inſpiration, or divine aſſiſtance, of the ſacred writers of the New Teſtament, as will aſſure us of the truth of what they write, either by inſpiration of *ſuggeſtion* or *direction* only, but not for ſuch an inſpiration as implies, that even their words were dictated, or their phraſes ſuggeſted to them by the Holy Ghoſt. Dr. Whitby cannot allow, 1. For any ſlips of memory in the compilers of the ſacred books of the New Teſtament; for though theſe are allowed by ſome in matters of ſmall conſequence, as they are pleaſed to ſtyle them, yet it is of great conſequence that we do not own them: for, if you grant they have ſlipped at all, by what rules can we affirm that they have not ſlipped above an 100 times, or even in moſt of their hiſtorical relations? 2. He cannot grant, that the apoſtles determined any matters of practice merely from rules of human prudence, without the guidance and direction of the holy ſpirit. 3. Dr. Whitby does not allow that St. Paul doth not always uſe the beſt arguments, but ſuch as are beſt ſuited to the capacities and notions of thoſe to whom he writes: if ſo, by what rules ſhall we be able to diſtinguiſh betwixt his arguments, on which we may ſafely rely, as being abſolutely true, and thoſe which are only accommodated to the notions of thoſe with whom he had to do?

Dr. Whitby next proceeds to lay down the arguments which prove, that the apoſtles were aſſiſted and preſerved from error by the ſpirit of God, and were enabled to deliver to us an unerring rule of faith. Theſe arguments are the following: 1. Their aſſertions concerning their own writings, and what they ſay reſpecting the declarations made, the doctrines delivered, and the directions given in them. 2. The things which God ſpake to his ſervants the prophets are ſtyled the things which I command by my ſpirit. (Zech. i. 6.) But the apoſtles were thus aſſiſted. Peter ſays they preached the goſpel by the Holy Ghoſt ſent down from heaven; they ſpake as they were moved by the Holy Ghoſt; they ſtyle themſelves prophets and apoſtles: they challenge a like illumination with the ancient prophets: they pretend to teach others in words taught them by the Holy Ghoſt. In all theſe ſayings they muſt have been guilty of a falſe teſtimony concerning God, and muſt impoſe upon the church of Chriſt, if no ſuch aſſiſtance of the holy ſpirit was imparted to them. 3. The infallible aſſiſtance granted to the apoſtles is inferred from our Saviour's promiſe to them, repeated on different occaſions. 4. The ſacred records were to be a ſtanding rule of faith through all ages; and therefore in all things propounded in them to our faith, they muſt contain a divine teſtimony, or a revelation of the will of God. 5. That the apoſtles and writers of the New Teſtament were aſſiſted both in their preaching and writing by the ſpirit of God, is atteſted by Chriſtians of all ages from the beginning.

Dr. Benſon, in his "Diſſertation on Inſpiration," publiſhed in his "Commentary on the Epiſtles," and included in biſhop Watſon's "Collection of Tracts," obſerves, that many of the difficulties and objections that have been raiſed concerning inſpiration have been very much owing to the miſtaken accounts given by ſome of the friends to revelation. What he takes to be the genuine account, appears, at firſt view, eaſy and natural, and alſo, upon examination, the moſt unexceptionable. It is this: as Moſes retained in his mind the perfect and entire idea of the pattern ſhewn him in the mount, according to which model he was to make all things; ſo the apoſtles, and they alone, had in their minds the full and complete ſcheme of whatever they were to preach or write concerning the Chriſtian doctrine. And according to that model they were to found and erect the Chriſtian church. Not that they had the whole ſcheme of the Chriſtian revelation in its utmoſt extent fully communicated to them at once, the contrary of this is evident; for on the day of pentecoſt, the twelve apoſtles of the circumciſion do not appear to have received any more than the revelation of that goſpel, which they were to preach to Jews only. It was ſome years after that they had the particular revelation concerning their going to the devout Gentiles, and concerning the goſpel which they were to preach to them: and it was a long time before the particular revelation was communicated to the apoſtles of the uncircumciſion, concerning their going among the idolatrous Gentiles, or what goſpel they were to preach to them. And finally, different apoſtles of both claſſes had, beſides the general ſcheme, different revelations communicated to them. What is meant is this, that they had by immediate revelation the whole ſcheme of what they were to preach to the Jews, before they addreſſed themſelves to the Jews; and the whole ſcheme of what they were to preach to the devout or idolatrous Gentiles, before they addreſſed themſelves to devout or idolatrous Gentiles; and that they retained in their minds conſtantly the complete idea of the whole ſcheme, after it was communicated to them. From this conſtant fund of knowledge, they were enabled clearly to determine (as far as any caſe required) what was, or was not, the Chriſtian doctrine. This revelation of the whole ſcheme of the religion of Jeſus is, as Dr. Benſon apprehends, what St. Paul underſtood by the word of wiſdom, which ſtands firſt in the order of ſpiritual gifts; 1 Cor. xii. 18. Though the evangeliſts and prophets had ſome of the inferior gifts of the ſpirit, yet it was what they had received from the apoſtles, that they were to teach and to commit to faithful men, who were to teach others. The Old Teſtament prophets were not under a conſtant divine inſpiration, unleſs we except Moſes during the time in which he was erecting all things, according to the pattern ſhewn him in the mount: but the apoſtles had this fund of illumination conſtantly reſiding within them, from the time of its being communicated to the end of their lives. Chriſtian prophets, being of an order inferior to the apoſtles, were neither under conſtant inſpiration, nor had they at any time any more than particular revelations, relating to particular caſes. Dr. Benſon ſuppoſes, that the books of the New Teſtament derive their infallibility from their being written, taught, reviewed, or approved of by ſome of the apoſtles, who alone had this fund of knowledge conſtantly reſiding in them. Whenever, therefore, they ſpoke or wrote concerning Chriſtianity, this fund of revelation kept them right. But they were reaſonable creatures as well as inſpired apoſtles, and therefore could ſpeak or write about common affairs, as men that have the uſe of their reaſon, without any inſpiration, can eaſily do; inſtances of which frequently occur. Upon this ſyſtem, ſuch things only are aſcribed to inſpiration, as (all circumſtances conſidered) required inſpiration; and ſuch things to human reaſon, as human reaſon alone was capable of.

It appears by citations from the writings of the primitive fathers, Clemens Romanus, Polycarp, Juſtin Martyr, Clemens Alexandrinus, Origen, Tertullian, &c., that moſt of them maintained the plenary ſuperintendent inſpiration of the ſacred writers, and particularly of the apoſtles. This kind of inſpiration ſome have conceived neceſſary to vindicate the credibility of the doctrines and the authority of the precepts which they delivered under a divine commiſſion. Others, however, have objected to this plenary inſpiration; and allege miſtakes and contradictions which occur in the hiſtory of their conduct and in their writings, ſee Matt. x. 19, 20; Mark, xiii. 11; compared with Acts, xxiii. 1–6. It has been ſaid that the apoſtles did not ſeem to apprehend each other to be inſpired, as appears by their debating with each other in the council at Jeruſalem (Acts, xv.), and by Paul's blaming Peter (Gal. ii. 24.); and it is farther urged, that the Chriſtians in thoſe early days did not apprehend them to be infallible, ſince their conduct was in ſome inſtances queſtioned and arraigned. (Acts, xi 2, 3. xxi. 20—24.) It has been alſo ſaid, that Paul, who aſſerts himſelf to have been inferior to none of the reſt of the apoſtles (2 Cor. xi. 5. xii. 11.) ſpeaks of himſelf in ſuch a manner, as plainly to ſhew that he did not apprehend himſelf under ſuch a plenary inſpiration (1 Cor. vii. 10. 12. 25. 40. 2 Cor. xi. 17.); nor do we find that any of the apoſtles introduce their diſcourſes with ſuch clauſes as the prophets uſed, to declare that they ſpoke as the oracles of God. To this objection, however, it has been replied, that their diſtinguiſhing in the caſes here referred to ſeems ſtrongly to imply, that their deciſions in *other* points of doctrine and duty were by "immediate revelation from Chriſt." It has been alſo pleaded, againſt the plenary inſpiration above ſtated, that it is inconſiſtent with that diverſity of diction or ſtyle which occurs among the ſacred penmen. Is not the ſtyle, it is ſaid, of all inſpired writers the ſame, as being the ſtyle of the ſame ſpirit by which they were alike directed? It is argued on the other hand, that in ſome ſenſe the ſtyle of all thoſe writers is the ſtyle of the holy ſpirit, who ſpoke by them, and was the ſame in them all; but that the holy ſpirit ſhould always employ the ſame ſtyle in conveying celeſtial truths to men, is no more neceſſary than that he ſhould always uſe the ſame language. We have no reaſon to doubt that the ſacred writers were permitted to employ the ſtyle and idiom moſt familiar to them, in delivering the truths with which they were inſpired. So far only were they over-ruled in point of expreſſion, by the divine ſpirit, that nothing could be introduced tending in any way to obſtruct the intention of the whole. And ſometimes, eſpecially in the prediction of future events, ſuch terms would be ſuggeſted as would, even beyond the prophet's apprehenſion, conduce to further that end. But this doctrine, it may be ſaid, is liable to an objection from the gift of tongues conferred on the apoſtles and others for the promulgation of the goſpel. In the languages with which thoſe primitive miniſters were miraculouſly furniſhed, it may be objected they could have no ſtyle of their own, as a ſtyle is purely the effect of habit, and of inſenſible imitation. This objection, however, is eaſily obviated: 1ſt, as they received by inſpiration thoſe tongues only of which they had previouſly no knowledge, it is not probable, at leaſt it is not certain, that this gift had any place in the writings of the New

Teſtament; that in moſt of them it had not is manifeſt. But, 2dly, if in ſome it had, the moſt natural ſuppoſition is, firſt, that the knowledge of the tongue with which the Holy Ghoſt inſpired the ſacred writers, muſt have been in them preciſely ſuch a knowledge, and ſuch a readineſs in finding words and expreſſions, as is in others the effect of daily practice. This is even a neceſſary conſequence of ſuppoſing that the language itſelf, and not the words of particular ſpeeches (according to the notion of Dr. Middleton, in his "Eſſay on the Gift of Tongues") was the gift of the ſpirit: And, 3dly, that their acquaintance with the tongues, ſupernaturally communicated, muſt have been ſuch as would render their teaching in it beſt adapted to the apprehenſions of the people with whom they would be moſt converſant, or ſuch as they would moſt readily have acquired in the natural way. Now on this hypotheſis, which on many accounts appears the moſt rational, the influence of habit, of native idiom, and of particular genius and turn of thinking, would be the ſame on the writer's ſtyle as though he had acquired the language in the ordinary way. Becauſe Cicero and the Greek philoſophers were of opinion, that if Jupiter ſpoke Greek, Dr. Middleton cannot conceive, that a ſtyle ſo unlike Plato's as that of the evangeliſts, can be the language of inſpiration, or be accounted worthy of God. But it was not, we know, peculiar to the Greeks or to the apoſtolic age to ſet too high a value on the words which man's wiſdom teacheth. See more on this ſubject in Campbell's Preliminary Diſſertations, Diſſ. 1.

It has been obſerved, in reference to the ſubject of inſpiration, that our Lord's evangeliſts report our Lord's diſcourſes with very great variations in their particular expreſſions; and hence ſome authors have been led to give up the opinion of the inſpiration of the evangeliſts, as writers. Thus they ſay, they are able to place the goſpel hiſtory on the ſame unexceptionable footing with other credible hiſtories, reſting on independent teſtimonies, in conſequence of their agreeing in all matters of importance, and appearing to be independent of each other, by their diſagreement in matters of no importance. By this means they alſo diſencumber the evidence of the goſpel hiſtory of many objections inſignificant indeed in themſelves, but rendered of the greateſt magnitude, and even abſolutely inſuperable by thoſe who profeſs to maintain the plenary inſpiration of the ſcriptures. Dr. Prieſtley is one of thoſe writers who has adopted this hypotheſis. He ſays, however, he is far from denying all inſpiration; but only the univerſal and infallible inſpiration of the ſcripture hiſtorians as "writers." When the prophets or apoſtles worked miracles, or delivered prophecies, and other meſſages from God, they muſt have been inſpired. Paul alſo ſeems to ſay, that he received his knowledge of the goſpel by a perſonal communication from Chriſt after his reſurrection. (Prieſtley's Preface to his Harmony.) After all, it ſhould be remembered that our Lord made an expreſs promiſe to his apoſtles, that "the ſpirit of truth ſhould lead them into all truth, and bring all things to their remembrance whatever he ſaid unto them," John, xiv. 26; and this promiſe ſeems to warrant that notion of inſpiration which we have ſtated towards the beginning of this article.

Michaelis, (Introduction to the New Teſtament) after weighing, with all that care and attention which ſo important a ſubject requires, the arguments which may be advanced on both ſides, thinks it adviſable to divide the queſtion. To the epiſtles, inſpiration is of real conſequence; but with reſpect to the hiſtorical books, *viz.* the Goſpels and the Acts of the Apoſtles, we ſhould really be no loſers if we abandoned the ſyſtem of inſpiration, and in ſome reſpects have a real advantage. We ſhould be no loſers if we conſidered the apoſtles, in hiſtorical facts, as merely human witneſſes, as Chriſt himſelf has done in ſaying, "Ye alſo ſhall bear witneſs, becauſe ye have been with me from the beginning." (John, xv. 27.) And no one that attempts to convince an unbeliever of the truth of Chriſtianity, would begin his demonſtration by pre-ſuppoſing a doctrine which his adverſary denies, but would ground his arguments on the credibility of the evangeliſts as human hiſtorians for the truth of the miracles, the death and the reſurrection of Chriſt. Even thoſe who examine the grounds of their faith for their own conviction, muſt treat the evangeliſts as human evidence, ſince it would be arguing in a circle to conclude that the facts recorded in the goſpels are true, becauſe they are inſpired, when we conclude the ſcriptures to be inſpired in conſequence of their contents. In theſe caſes, then, we are obliged to conſider the evangeliſts as human evidence, and it would be no detriment to the Chriſtian cauſe to conſider them at all times as ſuch in matters of hiſtorical fact. We find it no where expreſsly recorded that the public tranſactions which the apoſtles knew by their own experience, and of which St. Luke informed himſelf by diligent inquiry, ſhould be particular objects of divine inſpiration. We ſhould even be conſiderable gainers, in adjuſting the harmony of the goſpels, if we were permitted to ſuppoſe that ſome one of the evangeliſts had committed an immaterial error, and that St. John has rectified ſome trifling miſtakes in the preceding goſpels. The moſt dangerous objections that can be made to the truth of our religion, and ſuch as are moſt difficult to anſwer, are thoſe drawn from the different relations of the four evangeliſts. Mr. Kiddle, in the beginning of the ſecond ſection of his "Eſſay on Inſpiration," entertains ſentiments ſimilar to thoſe of Michaelis; now, if we advert to the ſentiments of Grotius, already recited, and which gave riſe to the famous theological diſputes between the Dominicans and the Jeſuits, will the diſtinction between the inſpiration of the hiſtorical books, and that of the epiſtles, appear to be new? As to the writings of thoſe that were apoſtles, Michaelis maintains that their inſpiration depends on their authenticity. If they are written by the apoſtles, to whom they are aſcribed, we conſider them as divinely inſpired: if not written by apoſtles, they can make no pretenſion to inſpiration. But it may be aſked, on what argument the poſition is grounded, that the writings of the apoſtles, if genuine, are inſpired? It is anſwered, on the teſtimony of Chriſt and his apoſtles, which is credible and ſacred, becauſe they have confirmed their doctrines by numberleſs miracles. But, where is this evidence recorded? It is certain, in the firſt place, that the apoſtles muſt be regarded not only as prophets, but as greater than prophets. (Mark, xi. 9—11.) Again, if we conſider Chriſt's more immediate promiſes of inſpiration to the apoſtles, we ſhall find that he has given them, in the moſt proper ſenſe of the word, at three ſeveral periods: 1ſt, when he ſent the apoſtles to preach the goſpel (Matt. x. 19, 20); 2dly, in holding a public diſcourſe relating to the goſpel, at which was preſent a conſiderable multitude (Luke, xii. 11, 12.); 3dly, in his prophecy of the deſtruction of Jeruſalem. (Mark, xiii. 2. Luke, xxi. 14, 15.) It is true, that when we argue from their inſpiration on theſe occaſions to the inſpiration of their writings, we draw a concluſion "a minore ad majus," but it is a concluſion to which no rational objection can be made; for if they were to expect inſpiration for thoſe ſpeeches and anſwers, which were only temporary, and in which they appeared rather as advocates than teachers, how much more reaſon had they to expect inſpiration in thoſe writings which were to ſerve as a ſtandard of faith to poſterity? Michaelis conceives, that Chriſt alluded to the future writings of the apoſtles, when he ſaid to Peter, "Thou art Peter" (*i. e.* a rock), &c. Another promiſe, firſt given to Peter, and afterwards extended to all the apoſtles, occurs in Matth. xvi. 19. xviii. 18. If the authority here referred to was given to the apoſtles without reſerve, it is manifeſt, that, as often as they appeared as teachers of the goſpel, they were attended by a conſtant inſpiration, and of courſe when they committed the precepts of Chriſtianity to writing; or elſe, we muſt have recourſe to the hypotheſis, that the Deity permitted errors to intrude themſelves into the morality of the goſpels: this is highly improbable; but whichſoever hypotheſis we adopt, we ſhall come to this concluſion, that the moral precepts, which are contained in the writings of the apoſtles, are for us commands of the Deity. Moreover, the promiſes which were given by Chriſt in the night preceding his death, of the continual aſſiſtance of the Holy Ghoſt, deſerve particular attention; more eſpecially as they are recorded in the goſpel of St. John (ch. xiv. 16, 17. xv. 26, 27. xvi. 7—11.), who wrote with a particular view to ſupport the authority of the apoſtles againſt the Gnoſtics. Beſides, the apoſtles aſſert their own inſpiration. Thus St. Paul does, Gal. i. 11, 12. 1 Cor. xi. 23. 1 Cor. ii. 13. xiv. 37, 38; and 1 Pet. i. 12. As to thoſe books of the New Teſtament, which were written by the aſſiſtants of the apoſtles, *viz.* the goſpels of St. Mark and of St. Luke, and the Acts of the Apoſtles, Michaelis heſitates in admitting their inſpiration. See Mark and Luke.

Among the heathens, the prieſts and prieſteſſes were ſaid to be divinely inſpired, when they gave oracles.

The poets alſo laid claim to it; and to this end they always invoked Apollo and the muſes at the beginning of any great work.

INSPISSATING, in *Pharmacy*, an operation whereby a liquor is brought to a thicker conſiſtence, by evaporating the thinner parts.

Thus, juices, as that of liquorice, are inſpiſſated.

INSPRUCK, in *Geography*, a town of Germany, and capital of the Tyroleſe, ſituated on the Inn. The ſuburbs without the walls are large, and occupied by palaces, churches, and convents. This town is the reſidence of the ſupreme repreſentative and aulic chamber, of the reviſion-judicatory of the counties of the Lower and Upper Auſtria, and alſo of the regency or lords-juſtices. In the middle of the Franciſcan church is a magnificent monument, on the top of which is a metal ſtatue of Maximilian I. in a kneeling poſture, ſurrounded by four others repreſenting the Virtues; and in white marble are exhibited the exploits of that emperor. There are ſome other coſtly curioſities in this place. The gymnaſium of the Jeſuits was converted by the emperor Leopold into an univerſity in 1672, calling it "Cæſareo-Leopoldina;" and in 1745 Maria Thereſa preſented to it the collection of books, formerly kept at the citadel of Ambras, together with other books out of the imperial library at Vienna. This town was taken by the French in 1805: 28 miles N. of Brixen. N. lat. 47° 16′. E. long. 11° 30′.

INSTALLMENT, a ſettling or inſtating a perſon in a dignity, as that of a chancellor in one of our univerſities, &c.

The word is derived from the Latin *in*, and *ſtallum*, a term uſed for a ſeat in the church, in the choir, or a ſeat or bench in a court of juſtice, &c. though Voſſius is of opinion the word is of German origin.

Inſtallment is chiefly uſed for the induction of a dean, prebendary, or other eccleſiaſtical dignitary, into the poſſeſſion of his ſtall, or proper ſeat, in the cathedral church to which he belongs.

This is ſometimes alſo called *inſtallation*.

Inſtallment is likewiſe uſed for the ceremony, whereby the knights of the Garter are placed in their rank, in the chapel of St. George, at Windſor; and on many other like occaſions.

INSTANT, ſuch a part of duration, wherein we perceive no ſucceſſion; or it is that which takes up the time of only one idea in our minds.

The ſchoolmen diſtinguiſh three kinds of inſtants; a *temporary*, a *natural*, and a *rational* inſtant.

Instant, *Temporary*, is a part of time immediately preceding another: thus, the laſt inſtant of a day precedes immediately and really the firſt inſtant of the following day.

Instant, *Natural*, is what we otherwiſe call a *priority of nature*, which obtains in things that are ſubordinated in acting: as, firſt and ſecond cauſes; or cauſes and their effects: for the nature of things requires, that if there be a ſecond cauſe, there muſt be a firſt; and that there muſt be a cauſe, if there be an effect.

Instant, *Rational*, is not any real inſtant, but a point which the underſtanding conceives to have been before ſome other inſtant, founded on the nature of the things which occaſions it to be conceived. For inſtance, as God has made ſeveral things voluntarily, which he could otherwiſe have let alone; there is a reaſonable foundation to conceive God, ſuch as he is in himſelf, before he had made any of thoſe voluntary determinations: but as there was no real inſtant when God had not formed any determination, this inſtant is called a *rational* inſtant, by way of oppoſition to an inſtant of time.

INSTANTANEOUS Action. See Action.

INSTANTER, *Trial*, in *Law*. See Reprieve.

INSTAURATION, the re-eſtabliſhment, or reſtauration, of a religion, a church, or the like, to its former ſtate.

The word is by ſome derived from the old Latin *inſtaurum*, which ſignified the ſtock of things neceſſary for the tilling and managing of grounds; as cattle, tools, harneſs, &c. The word inſtaurum is only of the middle age; but inſtauratio is of much greater antiquity, and by ſome is derived from *inſtar*, *like;* as importing a thing's being brought to its former likeneſs or appearance.

INSTEP, in the *Manege*, is that part of the hinder leg of a horſe that correſponds to the ſhank in the fore-leg, extending from the ham to the paſtern joint.

INSTERBURG, in *Geography*, a town of Pruſſian Lithuania, containing two churches, about 350 houſes, and 3000 inhabitants. The principal articles of its trade are corn and beer; 44 miles E. of Konigſberg. N. lat. 54° 35′. E. long. 22° 21′.

INSTINCT, a natural diſpoſition, or ſagacity, wherewith animals are endued; and by virtue whereof they are enabled to provide for themſelves, and know what is good for them, and are determined to preſerve and propagate their ſpecies.

The term *inſtinct*, however, has been variouſly explained and defined. Inſtinct, according to Dr. Reid, is a natural blind impulſe to certain actions, without having any end in view, without deliberation, and very often without any conception of what we do; and he conſiders inſtinct as one ſpecies of the mechanical principles of action, the other being habits. An ingenious writer, of whoſe obſervations we avail ourſelves in the compilation of this article, defines inſtinct to be a tendency implanted in the minds of animals, when under the influence of certain feelings or ſenſations, to perform ſpontaneouſly, unerringly, independently of all teaching and experience, and without any determinate view to conſequences, certain actions neceſſary for the preſervation of the individual and the continuation of the kind.

Inſtinct in brutes bears ſome analogy to reaſon in men. There have been many ſyſtems adopted to explain the principles which produce and direct the ſpontaneous actions of brute animals.

Many of the ancient philoſophers aſcribed to brutes an underſtanding differing only in degree from that of man, and attributed their inferiority to the want of proper and ſufficient bodily organs. This ſyſtem has been very ſtrenuouſly ſupported by M. Helvetius, de l'Eſprit, tom. i. p. 2. &c. Among the moderns the learned Cudworth endeavoured to explain the inſtinct of animals, by means of a certain plaſtic nature. Des Cartes thought that all the actions of brute animals might be explained by the ſimple laws of mechaniſm, and conſiders them as machines totally devoid of life and ſentiment, but ſo curiouſly conſtructed by the Creator, that the mere impreſſions of light, ſound, and other external agents, on their organs, produced a ſeries of motions in them, and cauſed them to execute thoſe various operations, which had before been aſcribed to an internal principle of life and ſpontaneity. But the actions and manners of animals, which are totally incompatible with the mere principles and laws of mechaniſm, evince the abſurdity of this opinion. The dogma of Des Cartes is ſaid to have been firſt introduced by Pherecydes, the maſter of Pythagoras; and though Des Cartes had the merit of developing and applying this hypotheſis, the doctrine was before publiſhed by the Spaniard Pereira. M. Buffon adopts the opinion of Des Cartes in part, but grants brute animals life, and the faculty of diſtinguiſhing between pleaſure and pain, together with a ſtrong inclination to the former and averſion from the latter. By theſe inclinations and averſions he undertakes to account for all, even the moſt ſtriking operations of animals; affirming, that, in conſequence of impreſſions made on the brain, by means of the ſenſitive organs, and by the re-action of the brain and nerves on the muſcles, theſe machines acquire a motion conformable to the nature of the animal, and of the impreſſions of the different objects which act upon their organs, and excite deſire or averſion. See BRUTES.

The pre-eſtabliſhed harmony of Leibnitz has alſo been applied to explain the actions of brute animals. Others have conſidered the actions of animals as produced by the conſtant and immediate influence of the divine energy, directing all their inclinations and motions: ſuch appears to have been the opinion of Mr. Addiſon, in the ſecond volume of the Spectator. The late ingenious Hermann Samuel Reimar, profeſſor of philoſophy at Hamburgh, has enumerated and expoſed theſe and other opinions, with regard to the inſtinct of animals, in his Obſervations Phyſiques, &c. publiſhed in two vols. 12mo. at Amſterdam and Paris, 1770: and, defining inſtinct, in the moſt comprehenſive ſenſe of the word, to be every natural inclination, accompanied with a power, in animals, to perform certain actions, divides inſtincts into three heads. The firſt, which he calls *mechanical inſtincts*, belong to the body conſidered as an organized ſubſtance, and are exerciſed blindly and independently of the will of the animal. Such are thoſe which produce the motion of the heart and lungs, the contraction and dilatation of the pupil, digeſtion, &c. This claſs of inſtincts is poſſeſſed in common both by men and brutes, and in ſome meaſure even by vegetables. The ſecond claſs comprehends thoſe which he terms *repreſentative* inſtincts, which conſiſt partly in the power of perceiving external objects by their preſent impreſſion on the ſenſes, and partly in the faculty of rendering the ideas of theſe objects preſent to the mind by the powers of imagination, or of memory, in a lax ſenſe of the word. Theſe are common to men and other animals, excepting that brutes poſſeſs only the faculty of imagination in common with us, and not that of memory, in the ſtrict and proper ſenſe of the word. Indeed this author endeavours to prove, that the knowledge of brutes does not merely differ in degree from that of man, but that it is of a kind entirely different from it; and that they are incapable both of memory and reaſoning: the faculty of imagination ſerving to give them a confuſed idea of events that are paſt, by the view, or other impreſſions of objects that are preſent. The third and principal claſs of inſtincts is that which comprehends all thoſe which M. Reimar calls *ſpontaneous*. This ſpecies of inſtinct is not attended with any power of reflection, determining the animal to decide freely between two different modes of action preſent to his imagination; nor is it merely corporeal or mechanical. It is put into action by the natural and primitive principle of ſelf-love, implanted in all animated beings; or by a love of pleaſure and averſion to pain, producing a voluntary inclination to perform certain actions which tend to their well-being and preſervation. To the performance of theſe actions they are particularly prompted by their preſent ſenſations, by imagination ſupplying the place of memory, and by other cauſes. The wonderful effects produced by theſe inſtinctive appetites, are farther to be attributed to the exquiſite mechaniſm in their bodily conformation, particularly in the ſtructure of the various organs with which they execute their operations, and to the ſuperior perfection and acuteneſs of their external ſenſes, by which they are quickly and diſtinctly informed of thoſe qualities of objects which moſt materially concern them. In order to account for the more curious and ſurpriſing operations of brute animals, M. Reimar adds two other principles, *viz.* 1ſt, an internal diſtinct perception of the preciſe power and proper uſe of their various bodily organs, together with an innate knowledge of the qualities of thoſe objects around them in which they are intereſted; and, 2dly, certain innate and determinate powers and inclinations, impreſſed by the Author of nature, *à priori*, on the ſoul itſelf; by which they are arbitrarily, and without their own knowledge or conſciouſneſs, directed and irreſiſtibly impelled to the performance of theſe various operations which they execute with ſuch unremitting induſtry and art. Theſe determinate forces, which conſtitute the principal part of M. Reimar's ſyſtem, are no where ſo viſible and diſtinguiſhable as in that numerous ſet of inſtincts which he claſſes under the title of the *induſtrious* inſtincts of animals. For a farther account of this ſyſtem we muſt refer to the work itſelf, or to an abſtract of it, with ſeveral of the author's illuſtrations, in the Monthly Review, vol. xlv. p. 533, &c.

The majority of philoſophers, even in Des Cartes's time, maintained, that the actions of the brutes were moſtly *inſtinctive*, and not mechanical. This prevailing ſentiment was altered a little by a wrong application of the principles of Locke. But the balance was ſoon afterwards reſtored to its former preponderance in behalf of *inſtinctive* principles, by the writings of lord Shafteſbury and Dr. Hutcheſon; and ſtill more particularly by thoſe of Dr. Reid. Some authors, who, with Locke, reject innate notions and innate principles, both ſpeculative and practical, allow that the mind acts ſometimes *inſtinctively*; others, who reject Locke's ideal theory altogether, detail a great number of inſtinctive principles of mind; whilſt a third claſs of writers will have the actions, that have been generally denominated *inſtinctive*, to be either habitual, aſſociated, or mechanical. Nor does the matter reſt here: for ſome authors of a very modern date go ſo far even as to maintain that the word inſtinct is unphiloſophical; ſince all that has been referred to this principle, whether in man or in the brutes, may be the reſult of experience, or of imitation.

Some writers confound the actions that have been generally deemed *inſtinctive* with thoſe that ſpring from *reaſon;* ſome with thoſe that ſpring from *mechaniſm;* and others with ſuch as ſpring from *habit* and *aſſociation.* But it is eaſy, we think, to diſtinguiſh them from each and all of theſe, by pointing out actions which differ from ſuch as are called *rational, habitual,* or *mechanical.* An action is called *rational* when it is performed under the influence of a *motive;* that is, *with a view to conſequences:* Thus, to worſhip the Deity for having created us, for his goodneſs towards us, and that he may reward us hereafter, is a *rational action.* Some are of opinion that the *motive,* or the end we have in view in our *rational actions,* is the cauſe of theſe actions; but for our part, as we think that the human mind can act not only in oppoſition to the ſtrongeſt *external motive,* but againſt all external motives whatever, *properly ſo called,* we cannot help thinking it more correct to call them ſimply *inducements,* and to conſider the mind itſelf ſolely and properly as the *cauſe.* *Mechanical* actions alſo have a cauſe as well as thoſe that are rational; namely, *mechaniſm* or *organization.* But this cauſe is not an end propoſed, or a *motive;* neither is it an inward feeling, diſpoſition, or ſenſation: Thus a clock goes through its courſe of hours, minutes, and ſeconds, without a view to conſequences, without *ſpontaneity,* and even without being able to check its own action. To this claſs belong the actions of the heart and arteries, the vermicular action of the inteſtines, and thoſe of ſecretion and reſpiration in animals. *Inſtinctive* actions may be traced to a cauſe as well as both the preceding; but this cannot be referred to the claſs of *motives,* as they are not performed with a view to conſequences; neither can the cauſe be ſaid to be *mechaniſm,* as they are accompanied with *ſpontaneity.* The proper cauſe, however, is the *internal feeling, ſenſation,* or *diſpoſition,* that leads to the performance of them, without deſign or intelligence, on the part of the animal. Thus an infant, in a few minutes after birth, ſeeks the breaſt without any knowledge whatever of its neceſſity for his preſervation; and a pair of young birds, without teaching or experience, build their firſt neſt with as much ſkill and exactneſs as the oldeſt of their tribe could do; and that, too, of the cuſtomary materials of their ſpecies, and in the ſituations beſt calculated for depoſiting and hatching their eggs. *Inſtinct* and *mechaniſm* have been oftener confounded with each other, particularly of late, than any other of thoſe principles of action which we are conſidering; and yet we cannot help thinking that the diſtinction between *habit* and *inſtinct* will not appear as palpable as thoſe we have already made, particularly as ſome *habits* are formed at ſo early an age that it is very difficult to aſcertain whether the actions that ſpring from them are from *habit* or from *nature.* But ſuppoſing ſuch a principle as inſtinct, ſuch as we have deſcribed it, the actions that ſpring from it muſt differ from ſuch as are habitual in this, "that the former muſt be from *nature,* and the latter *acquired.*" Habit has been defined to be a facility of doing, and not only a facility, but alſo a proneneſs to do certain things from having done them frequently before. This definition, however, is manifeſtly not applicable to *habits of art,* but only to ſuch as can be properly called *principles of action.* (See Habit.) Inſtinctive actions agree with habitual ones of the latter kind in this, that they are both performed without intelligence, will, or deſign; and this has accordingly induced Dr. Reid to confound them, and to claſs them, very improperly we think, under the head of mechanical actions. Their agreeing in a few particulars could not warrant him in reducing them to the ſame claſs, particularly when he tells us himſelf, that "the origin of one is natural, of the other acquired." But, beſides this, the habitual actions of man ſeem to want altogether that *ſpontaneity* which we obſerve in the inſtinctive actions of the other animals; ſuch as neſt-building, for inſtance, and the operations of bees, deſcribed in a ſubſequent part of this article, or the migrations of birds of paſſage "through the pathleſs air without chart or compaſs." One inſtance of an action confeſſedly habitual will illuſtrate this more fully. Let us take that motion of the eye-lids which occurs almoſt every inſtant. This action cannot be the neceſſary reſult of mechaniſm, as we ſee that children do not, for ſome days after birth, cloſe their eye-lids on the approach of external objects. But as ſoon as ſome object (ſuppoſe too much light) has made them feel inconvenience or pain, and thus produced a voluntary or mechanical motion of the eye-lids, this effect becomes gradually ſo intimately aſſociated with its cauſe, that even the appearance of the candle will produce the effect. And, finally, habit gives us ſo great a proneneſs to this action, that we perform it conſtantly, amidſt all our occupations, without conſciouſneſs, will, or ſpontaneity; and even without perceiving that, in every waking minute of our lives, we are ſeveral moments totally in the dark. And ſo far is this motion from being a voluntary act, that it requires a ſtrong exertion of will and attention to check it, even for a ſhort time; but do what we will, we can never check it altogether. To avoid being miſunderſtood, it will be neceſſary to illuſtrate more fully the diſtinction between *habits of art,* in which we acquire a facility only from frequent practice, ſuch as playing expertly on the violin or harpſichord, and *thoſe habits,* which, beſides *a facility,* induce alſo a *proneneſs* to act; for inſtance, in that motion of the eye-lids juſt deſcribed, and many other awkward motions and habits learned from bad example and bad company. This is the more neceſſary, as it has not been illuſtrated ſufficiently by any author with whom we are acquainted; and forcibly calls to our recollection the words of a French writer, who remarks: "Tout ſe tient dans un certain ordre de ſpéculations: Voulez vous développer une verité? Il faut en éclaircir vingt autres, qui l'avoiſinent, et dont la lumiere vient, pour ainſi dire, l'éclairer par réflexion." Habits of the latter kind may be properly called *principles* of action; *habits of art* cannot. Theſe require thought, attention, and will in the performance of their operations; whilſt the others require no ſmall exertion of thought, attention, and will to check them. Nor can they, even thus, be completely overcome, until, by repeated exertions, a counter habit is eſtabliſhed, which is the beſt way to obviate their effects. It was this that made Dr. Reid ſay, "I conceive it to be a part of our conſtitution, that what we have been accuſtomed to do we acquire not only a facility, but a proneneſs to do on like occaſions; ſo that it requires a particular will or effort to forbear it, but to do it requires, very often, no will at all. We are carried by habit, as by a ſtream in ſwimming, if we make no reſiſtance." Dr. Reid diſtinguiſhes theſe two ſpecies of habits as we do; but in ſome paſſages he ſeems to confound them, for he claſſes them and inſtinct under the head of mechanical principles. Thus, he ſays, "Habit differs from inſtinct, not in its nature but in its origin; the latter being natural, the former acquired. Both operate without will or intention, without thought, and therefore may be called mechanical principles." (See Habit.) From both theſe paſſages it would ſeem that he meant habit in general; for the aſſertions are not qualified in any ſhape. If ſuch was his opinion, his doctrine agrees exactly with that of Dr. Hartley, whoſe language affords no opportunity for being in doubt about his meaning. But, for our part, we cannot help thinking it more philoſophical to admit any poſſibly conceivable rapidity in our intellectual operations. than to ſuppoſe, that any action performed with ſo much correctneſs, and with ſuch rapidity, as violin and harpſichord playing in ſome inſtances, can be merely habitual, or automatic ; that is, in every one of its minute ſub-diviſions altogether unconnected with the exertions of the will. In habits of art, then, we deem it more correct to admit the interference of the will ; but in the other claſs, which only, becauſe they give not merely a facility, but alſo a proneneſs to act, ought to be called principles of action, we ſee no reaſon for admitting its interference in any reſpect. A different opinion ſeems to be maintained in a late elegant treatiſe, for whoſe author we have a high reſpect. Upon this we ſhall offer a few remarks ; but we have not as yet done with Dr. Reid. After having attentively examined what he has written on this ſubject, we do not think that he intended to include *habits of art* in the paſſages cited above. Surely ſo correct an obſerver of nature could not think, that in *habits of art*, ſuch as pin-making and violin playing, we acquire, from frequent doing, "not merely a *facility*, but alſo a *proneneſs* to do the ſame thing on like occaſions." In all habits of art we acquire more or leſs of facility, but ſurely no proneneſs, as Dr. Reid aſſerts of the habits he had in view in one of the paſſages cited above : for who can aſſert with any truth, that a violin-player feels a particular proneneſs, or inward impulſe, to play upon that favourite inſtrument, as often as it is preſented to him ? And yet he has acquired a facility in playing, from having often played before. The truth ſeems to be, that Dr. Reid, after ſtating the diſtinction of habits already mentioned, threw the *habits of art* into the back ground altogether. This, indeed, is ſtrongly confirmed by the circumſtance, that in the eſſay and chapters to which we allude, he treats only of what can be called *principles of action*, which he defines to be "every thing that incites us to act ;" and particularly when he tells us that *habits of art*, ſince they give only a facility, cannot with propriety be called principles of action. "Habit," he ſays, "is commonly defined *a facility of doing a thing, acquired by having done it frequently*. This definition is ſufficient for habits of art ; but the habits which may, with propriety, be called principles of action, muſt give more than a facility, they muſt give an inclination, or impulſe, to do the action ; and that, in many caſes, habits have this force, cannot be doubted." It deſerves to be remarked, that in this paſſage he does not ſay, that habits give a *proneneſs* (in his own words, an inclination or impulſe) to act in *every caſe*, which he ſhould have done, if he meant to bring habits of art under the obſervation. He only ſays, "that habits give an inclination or impulſe *in many caſes* ;" which ſeems to prove, that he meant only "thoſe habits, which may, with propriety, be called principles of action." This opinion is ſtill further ſtrengthened by the following extract : "Ariſtotle makes wiſdom, prudence, good ſenſe, ſcience and art, as well as the moral virtues and vices, to be *habits*. If he meant no more, by giving this name to all thoſe intellectual and moral qualities, than that they are all ſtrengthened and confirmed by repeated acts, this is undoubtedly true. I take the word in a leſs extenſive ſenſe, when I conſider *habits as principles of action*. I conceive it, &c." (as quoted above.) In this extract he tells us, that he takes the word habit in a confined ſenſe, meaning only ſuch *habits* as he calls *principles of action*. And he has already told us, that *habits of art* do not come under that denomination. If the latter part only of the paragraph be attended to, it ſeems to ſhew that Dr. Reid held the ſame opinion on this point with Hartley ; but if the whole be taken together, and interpreted with fairneſs, and conſidered in connection with our remarks on the ſubject, we think it will appear more probable, that Dr. Reid meant only a particular ſpecies of habits, thoſe which he calls *principles of action*, and that he did not intend to characterize ſuch habitual actions as violin and harpſichord-playing, as *involuntary* and *mechanical*. It muſt not be concealed, that profeſſor Stewart of Edinburgh ſeems to think otherwiſe of Dr. Reid's meaning ; and that he has proved, partly in conſequence of that opinion, that ſome of our habitual actions are under the guidance of the will. From the preceding remarks it will appear, that our opinion differs not from the learned profeſſor's, if he means only *habits of art :* but if he means to bring the other claſs of habits under the influence of the will, (as it is probable he does, for he talks of habitual actions in general, and does not even hint at a diſtinction,) we cannot help thinking, as even analogy itſelf affords no ſupport to this opinion, that he was ſwayed too much by an over-ardent zeal for premature generalization. It deſerves to be remarked, as an additional proof of the fairneſs with which we have interpreted Dr. Reid's opinion, that he ſays nothing of *habits of art* in his chapter on habit, except mentioning one ſolitary inſtance, merely to ſhew "the power of habits and their utility ;" whereas he expreſsly mentions, as belonging to that ſpecies which he calls *principles of action*, many "awkward habits in addreſs, motion, looks, geſture, and pronunciation, acquired by frequenting bad company ; to forbear which, when fully formed, a general reſolution (he ſays) is not ſufficient." He even affirms, that particular attention is neceſſary, on every occaſion, to reſiſt their impulſe, until they be undone by the habit of oppoſing them ; for *theſe habits* operate without intention." It is remarked by profeſſor Stewart, on the ſubject of habitual actions, "that the circumſtance of our inability to recollect our volitions does not authorize us to diſpute their poſſibility." To this obſervation we have no objection ; but when he further contends "that it does not add any force to the objection, to urge, that there are inſtances in which we find it difficult, or perhaps impoſſible, to check our habitual actions by a contrary volition ;" we muſt remark, that this very circumſtance, ſince it has not been obviated, renders the objection inſuperable, and the doctrine againſt which it militates, ſo far as that relates to the ſpecies of habits which we have called *principles of action*, altogether inconcluſive. Let any one try, by the moſt firm and perſevering efforts, to check for a ſhort time the moſt common of all habits, that of cloſing the eyelids, and he will find, though he may ſucceed for a few moments, that he cannot do ſo altogether. Nor is it an anſwer to this fact to ſay "that the contrary volition does not remain with us ſteadily, during the whole operation ; but is merely a general intention, or reſolution, which is baniſhed from the mind as ſoon as the occaſion preſents itſelf, with which the habitual train of our thoughts and volitions is aſſociated." For the time requiſite for trying this experiment, and being defeated in it, is ſo very ſhort, that the contrary volition may be eaſily kept in view, all the while, without its dwindling away into "a general intention or reſolution ;" and beſides, if the perſon who tries the experiment, thinks that he is unable to keep up the counter-volition ſteadily himſelf, he can eaſily have an aſſiſtant or two, to ſit near him, and remind him to keep his thoughts and attention fixed upon the object in view. Some may perhaps urge that this motion of the eyelids is *inſtinctive ;* but by the learned profeſſor himſelf it is allowed to be habitual. We may beſides remark, that there is a wide difference between our being unable to recollect the volitions, which in this theory are ſuppoſed to precede all our habitual actions, and that ſtate of mind in which we are not only not conſcious of any ſuch volitions, but fully aware that the habitual actions occur, even when we are conſcious of having exerted the ſtrongeſt efforts of volition to prevent them. But to conclude this preliminary, but neceſſary, diſcuſſion, we may, by way of recapitulation, obſerve, if the expoſition we have been giving be correct, that the difference between the four ſpecies of actions under one conſideration conſiſts nearly in the following circumſtances. That *rational* actions are done with *intelligence*, *will*, and *deſign* on the part of the agent; *inſtinctive* actions *ſpontaneouſly*, but with no proper intelligence or deſign in the doer; *mechanical* actions without will, *ſpontaneity*, deſign or intelligence; and *habitual* actions, like mechanical ones, (we mean the habits that may be properly called principles of action,) without ſpontaneity, deſign, or intelligence; but differing in this, that they are *accidental* in their origin, and in many inſtances capable of being checked and even removed by contrary habits; whereas *mechanical* actions, properly ſo called, are in a manner neceſſary in their origin (for inſtance circulation, ſecretion and reſpiration in animals), and can never be removed or ſuppreſſed altogether, without the deſtruction of the animal, by any voluntary effort of ours.

As we are of opinion, that the origin at leaſt of ſome of the actions of man cannot be explained, unleſs we admit the exiſtence of ſuch a principle as inſtinct, it becomes neceſſary to conſider ſome of thoſe actions of the lower animals, which are generally allowed to be inſtinctive. This ſtep ſeems the more neceſſary, as the exiſtence of inſtinct, even in the lower animals, ſeems of late to have been wholly denied, ſince it has been aſſerted, in a "New Syſtem of the Natural Hiſtory of Animals," publiſhed in Edinburgh, in 3 vols. 8vo. by Peter Hill, in 1791; "that the laws of analogical reaſoning do not juſtify the opinion, that the brutes act, on any occaſion, abſolutely without deſign." Whilſt, on the other hand, it has been maintained by Mr. Smellie, in his "Philoſophy of Natural Hiſtory," "that between reaſon and inſtinct there is no difference, and that the reaſoning faculty is itſelf the neceſſary reſult of inſtinct." Nothing can be more directly oppoſite than both theſe opinions; and like moſt extremes, nothing can be more eaſily ſhewn to be falſe. To prove that ſome of the natural operations of the lower animals are not performed with deſign, or with a view to conſequences, in oppoſition to the former, many examples will not be neceſſary; and firſt, let us attend to the operations of the winged tribe. The youngeſt pair of birds, it is known, without inſtruction or experience, build their firſt neſt of the materials commonly uſed by their ſpecies; in ſituations, whoſe privacy, &c. render them fit to afford them ſecurity, and convenient for incubation and the rearing of their young. It is alſo certain, that they ſhew equal ſkill with the oldeſt and moſt practiſed of their tribe, in the neatneſs, accuracy, and ſymmetry of their work. It is further known, whenever the climate or ſituation, or any change of circumſtances renders a change in the ſtructure of neſts neceſſary, that this change is made by all the individuals (young and old) of the ſame ſpecies equally, and that only when ſuch a change is neceſſary. Thus, "in countries infeſted with monkies, many birds, which, in other climates, build in buſhes and clefts of trees, ſuſpend their neſts upon ſlender twigs, and, by this ingenious device, elude the rapacity of their enemies." It is moreover certain, that no improvement has been made, within the memory of man, in the art of neſt-building, by any tribe, or by any of its individuals. Now the nature of all the arts with which we are acquainted is ſuch, and their hiſtory ſhews us, that they were firſt invented by ſome perſon, and then improved in the courſe of time, either by the inventor or by others, and finally brought to ſome degree of perfection. Hiſtory and experience alſo ſhew, that human arts are beſt known and practiſed with moſt ſkill and dexterity in general, by thoſe only to whom they have been taught; and that in different ages and countries they all undergo conſiderable variations. But in the arts of animals we obſerve no ſuch variations; nor can any individual be pointed out as the inventor, the improver, or the perfector of any of them; for inſtance, of neſt-building. Each of them is perfectly ſkilled in the workmanſhip of its tribe; we do not ſay that they know the nature and the rules of the different arts which they practiſe; but that they are acquainted with the mode of working in them to perfection. How many very ſimple arts do we daily ſee practiſed by our ſpecies, without being able to practiſe them, or learn them ourſelves. What a long apprenticeſhip is generally neceſſary before we can practiſe even ſome of the moſt common and neceſſary. A peaſant ſpends months and years under his ſimple roof, and yet is not able often to build ſuch a hut as that he inhabits. Birds require no ſuch teaching or experience: they ſerved no apprenticeſhips; and yet a pair of young birds kept ſolitary and ſequeſtered from their infancy, build exactly ſuch another neſt as that in which they themſelves had been brought into life. But what is the inference to be drawn from theſe facts? If the natural actions of the lower animals, for inſtance this of neſt-building, be all under the influence of motives, in other words, *rational*; we muſt conclude, ſince they are ſo invariable, either that their workmanſhip is perfect beyond the reach of improvement, or ſo imperfect as not to be capable of degenerating. The former of theſe concluſions cannot be ſupported, unleſs it be contended at the ſame time, that the lower animals have made more early and greater diſcoveries and advances in the arts and ſciences than we have. Nor will the latter be maintained by any man, who conſiders the ſtructure of a honey-comb, or who reflects, that all the ſkill of man has never yet excelled the workmanſhip even of a wren in the ſtructure of ſuch a neſt as he builds. However, if the ſuppoſition be admitted, the former ſeems the better inference. But, if this doctrine be true, we muſt ſay, that birds are good judges of climate and circumſtances; that they know the dangers and advantages reſulting from them, and the beſt methods for obviating the former and ſecuring the latter. We muſt ſay, that reaſoning ſhews them the neceſſity of equality in the ſtructure of their neſts; or when, after having been abſent for ſome time, they turn their eggs ſo as to heat them properly, and at all times equally, we muſt think, that they know heat, and even an equal diſtribution of it, to be neceſſary for incubation. But as none of theſe can, we think, be affirmed with the ſmalleſt appearance of truth, and ſince thoſe actions of birds are, without teaching, habit, or experience as perfectly performed by the young as by the old, and always ſo invariable, we muſt conclude, that in theſe inſtances we diſcover not the reaſoning of animals, pointing to conſequences and deviſing means, but the unerring reaſon and wiſdom of *Him* who made them, and implanted ſuch principles in their conſtitutions as guide them unceaſingly in the performance of their various natural operations, the complete purpoſes and utility of which *He* only knows. Our reaſoning is confirmed by that of Addiſon—"What," ſays he, "can we call the principle which directs every different kind of bird to obſerve a particular plan in the ſtructure of its neſt, and directs all of the ſame ſpecies to work after the ſame model? It cannot be *imitation*; for though you hatch a crow under a hen, and never let it ſee any of the works of its own kind, the neſt it makes ſhall be the ſame, to the laying of a ſtick, with all the other neſts of the ſame ſpecies. It cannot be *reaſon;* for were animals endued with it to as great a degree as man, their buildings would be as different as our's, according to the different conveniences that they would propoſe to themſelves." Some birds diſplay a wonderful ſhare of ſagacity in the proceſs of incubation and in rearing their young. Without attentive and cautious obſervation, one would be almoſt poſitive, that in every ſtep they are guided by reaſon. But it is eaſy to ſhew that this is not the caſe. Let us take a very familiar inſtance: a hen ſeeks a ſilent and an unfrequented place for her neſt; when ſhe has laid her eggs and began to cover them, ſhe takes care to turn them frequently, that the vital warmth may be communicated to all parts of them. When ſhe is obliged to leave them, in order to procure food, ſhe is ſure to return before they have time to cool, which would render them incapable of producing chickens. In ſummer ſhe will often ſtay away for two hours; but in winter, when the cold would deſtroy the principle of life, ſhe ſtays away a much ſhorter time. When the birth approaches, with how much nicety and attention does ſhe help the little ones to break their priſon. When brought forth, how cautiouſly does ſhe cover them from the injuries of the weather, provide them proper nouriſhment, and teach them to help themſelves. It deſerves alſo to be remarked, that ſhe forſakes the neſt if, after the uſual time of reckoning, the young do not begin to make their appearance. Can any thing have a greater appearance of reaſon and ſagacity than all this. "But, at the ſame time, the hen that has all this ſeeming ingenuity (which is indeed abſolutely neceſſary for the propagation of the ſpecies), conſidered in other reſpects has not the leaſt glimmering of thought or common ſenſe. She miſtakes a piece of chalk for an egg; and ſits upon it in the ſame manner; ſhe is inſenſible of any increaſe or diminution in the number of thoſe ſhe lays; ſhe does not diſtinguiſh between her own and thoſe of another ſpecies; and when the birth appears of ever ſo different a bird will cheriſh it for her own. In all theſe circumſtances, which do not carry an immediate regard to the ſubſiſtence of herſelf or her ſpecies, ſhe is a very idiot." None of theſe inſtances juſtifies the doctrine, "that animals, in all their natural operations, act with a view to conſequences." To confirm our reaſoning and opinion ſtill farther, out of the numberleſs examples afforded us by Natural Hiſtory, we ſhall content ourſelves with one, which, if we miſtake not very much, is deciſive of this quſtion. This we take from the operations of the bee, as it ſeems to act with a view to conſequences, and to be, as was ſaid of the ant, "haud ignara et non incauta futuri." Let us attend a little to the ſtructure of a honeycomb. The cells of the bees are equal and ſimilar; and of the three poſſible ways in which this can be effected, they have choſen the beſt for holding their honey and rearing their young. The cells are built on both ſides: they may then be placed exactly oppoſite one another, ſo that two would reſt upon the ſame bottom; or they may be ſo placed, that the bottom of one will reſt upon the point where the partitions meet on the oppoſite ſide. This latter mode gives them more ſtrength, and they are accordingly built thus. Further, the bottoms of the cells are not planes perpendicular to the ſides, but conſiſt of three planes meeting in a ſolid angle in the centre, exactly where the partitions on the oppoſite ſide croſs one another. And it has been demonſtrated, that this makes the cells ſimilar without loſs of room, and conſiderably ſpares both labour and materials. Thus, then, it is ſhewn, that bees build their cells ſo as as loſe no room; to have no uſeleſs partitions; in the ſtrongeſt poſſible manner; and with the leaſt poſſible expence of labour and materials. All this, as far as geometry and mathematics can ſhew it, has been rigorouſly demonſtrated by Mr. Maclaurin, and proves them, on the ſuppoſition that they act with a view to conſequences in this inſtance, more ſkilled in both theſe inſtances than the moſt philoſophical and learned men; and that too from the earlieſt ages. But as this is a doctrine too improbable to be inſiſted upon, we muſt rather conclude, that the bees, although they act geometrically, underſtand neither the rules nor the principles of the arts which they practiſe with ſuch accuracy; but that the geometry in this inſtance is in the Maker of the bee, "that Great Geometer, who made all things in number, weight, and meaſure." (Reid's Active Powers of Man, and the London Philoſophical Tranſactions.) Were a man to conſtruct ſo nice a piece of workmanſhip as a honeycomb, we ſhould immediately conclude, that he worked according to rule, and underſtood the principles upon which he proceeded. Is it neceſſary to remark, that we have no reaſon whatever for thinking, that bees underſtand one or the other? In the moſt complicated works of human contrivance, a man of equal knowledge and ſkill will comprehend the principles and general deſign of the artiſt: but to underſtand the rules and principles, which are ſo rigorouſly adhered to in the conſtructing of a honeycomb, is, and will always be, beyond the comprehenſion of the far greateſt part of mankind. The few inſtances of animal *inſtinctive* operations, which we have now briefly detailed, will, we hope, be ſufficient for the preſent: they correſpond fully with our notion and explanation of inſtinct, and ſerve our purpoſe, as well as a million of inſtances crowded together. But it is objected, that this inſtinct, which we call a ſimple, original principle, accommodates itſelf to circumſtances; that it is improved by experience and imitation; that no ſuch accommodation to circumſtances can take place without reaſoning, or a compariſon of ideas; and, therefore, that this principle of the conſtitution of the lower animals is not *inſtinct*, but *reaſon*. The inſtances to prove that inſtinct accommodates itſelf to circumſtances are numerous. Birds ſtay away from their eggs longer in warm than cold weather. The oſtrich in Senegal, where the heat is great, neglects her eggs during the day, but ſits on them during the night: but at the Cape of Good Hope, where the heat is leſs, ſhe ſits on them both night and day. In countries infeſted with monkies, birds, which in other climates build in buſhes and clefts of trees, ſuſpend their neſts upon ſlender twigs, and thus elude their enemies. The ſame ſpecies of birds build their neſts differently, when climate and circumſtances require it. We have numberleſs inſtances of this accommodation to circumſtances in the pairing inſtincts of animals. None, it has been obſerved, ever pair, except thoſe whoſe young require the nurſing care of both the parents. The extent and continuance of the parental care are in the proportion of the wants and helpleſſneſs of the young. When the wants of the young ceaſe, the mother withdraws her fondneſs, and leaves them to provide for themſelves; but the love of the parent may be lengthened out beyond its uſual time, as we ſee in birds, which continue to feed their young, if they are tied to the neſt, or confined within a cage, or by any other means appear to be out of a condition of ſupplying their own neceſſities. This laſt inſtance, whilſt it very finely exemplifies an accommodating inſtinct, affords the happieſt proof of the guardian care of a kind and parental Providence. In anſwer to the objection which theſe facts contain, it may be firſt obſerved, that taking inſtinct, as it is generally defined, to be a principle in the conſtitution of animals, given them by their Maker, for the purpoſe of preſerving the individuals and continuing the kind, in other words, a prediſpoſition to perform certain actions neceſſary for theſe ends, when incited by certain feelings or ſenſations, that its accommodating itſelf to circumſtances and ſituations is no argument againſt its exiſtence, nor a good proof, that it is the reſult of reaſoning; ſince *He*, who made it a part of the conſtitution of his creatures, knows, that the ſame ends muſt be often ſought by different means, particularly when times, places, and circumſtances are altered; and only manifeſts his wiſdom and goodneſs the more, by conſtituting this principle of ſuch a nature, as to vary when requiſite, and to change only when ſuch a change is neceſſary. Let us add to this, that did He not impart this accommodating property to inſtinct, it would not produce the effects for which it ſeems intended; as we know it to be impoſſible, that ſimilar means ſhould produce ſimilar effects, when circumſtances, climates, and ſituations, are different. Indeed this accommodating peculiarity, ſo far from being a good argument againſt it, is a neceſſary conſequence of inſtinct. The abettors of this principle do not maintain, that the accommodating variations will take place on every occaſion. They will occur only where the diſadvantages exiſt, againſt which the inſtinct is intended to provide. Inſtinctive actions take place when certain ſenſations exiſt, and when theſe do not exiſt, we cannot wonder that the actions do not occur. In the following remarks we follow the learned author of "Ancient Metaphyſics," a work, in which we find a juſt view of the ſubject of inſtinct. Before we poſitively conclude, that no accommodation to circumſtances can take place without reaſoning, or a compariſon of ideas, it may not be irrelevant to conſider ſome of the appearances which the vegetable and inanimate worlds exhibit. If, becauſe the operations of ſome animals are ſo artificial, and becauſe they ſometimes accommodate their actions to circumſtances, we muſt ſay, that they reaſon and compare ideas, we muſt contend, that vegetables and inanimate bodies do ſo likewiſe: we know, that a vegetable reared in a dark cellar, if ſome light be admitted, will bend itſelf towards the light: or, if made to grow in a flower-pot with its head downwards, that it will turn its head upwards, according to the natural poſition of a plant. Can it be maintained, that the plant in either caſe does what it does from any judgment or opinion, that it is beſt, and not from a neceſſary determination of its nature? The facts taken from the inanimate world are equally in point. How ſhall we account for the phenomena of elective attractions? when one body unites with another, and then, if a third is preſented to it, quits the firſt and unites itſelf with the other, ſhall we ſay that this is the effect of reaſoning and of a compariſon of ideas, and ſuppoſe, that this preference of the one to the other proceeds from any predilection or opinion, that it is better to cleave to one than to the other? What ſhall we ſay of the cryſtallizations and configurations of ſalts exhibited to us by the microſcope, ſo various and yet ſo conſtant and regular? Muſt we ſay, that their minute particles reaſon and compare ideas, becauſe their operations are ſo various, and, at the ſame time, ſo regular and conſtant? Or, if nobody affirms this, why ſhould we think, that the actions of animals, not more various and ſurprizing, not more conſtant or regular, than theſe motions of the ſalts, ſhould be the reſult of reaſoning and of a deduction of inferences? Should we not rather affirm, as thoſe inanimate ſubſtances arrange themſelves ſo regularly, and yet ſo variouſly, upon different occaſions, in conſequence of an original law of nature, that the benevolent Author of all ſuch laws, intending to diſplay his providence and wiſdom ſtill more conſpicuouſly in his animal kingdom, beſtowed upon his creatures this accommodating inſtinct, without which, (ſuppoſing that they act inſtinctively on any occaſion) the great purpoſes of their propagation and preſervation could never be attained? This objection, upon which we have been commenting, is contained in the "Syſtem of Natural Hiſtory" already mentioned in this article. The compilers of that work have been carried much too far in their zeal to do away Mr. Smellie's very unphiloſophical notions concerning inſtinct: and, although we have read over their opinions with much attention, we are ſtill at a loſs in ſome parts to comprehend their meaning. Their diſſertation on the ſubject is but ſhort, and yet, we think, they often contradict themſelves. One time you would ſuppoſe, that they admit ſuch a principle as inſtinct in the lower animals; at another they ſeem to reject it altogether. This latter, indeed, ſeems to be the faireſt account of their opinions. What theory they had in view, when they called inſtinct a *mechanical* principle, we know not. It could not be the exploded doctrine of Des Cartes, nor the equally unphiloſophical theory of Buffon, which has been ſo fully and ſo ably refuted by Condillac. Perhaps they referred to Dr. Reid's, who, as we have already obſerved, calls inſtinct a mechanical principle. We are equally at a loſs for their alluſions, when they call brutes *inſenſible inſtruments* under the influence of inſtinct, which they denominate a "myſterious influence." None of the advocates for inſtinct, ſo far as we know, haev ever held this abſurd opinion. On the contrary, they all allow them not only *ſenſibility*, but even *ſpontaneity*, in their inſtinctive operations. And, when they are allowed to poſſeſs theſe, we cannot deny them *conſciouſneſs*, by which they muſt know that they are acting. The ſupporters of inſtinct aſſert no more than this, ſince ſome of the natural operations of animals are ſo complicated, and yet ſo perfect and invariable, that it is irrational, with ſuch evidence as we poſſeſs, to ſuppoſe them acquainted with the rules of the arts which they practiſe, or the ends for which they operate. Theſe, however, are known to Him, and perhaps to Him only, who implanted ſuch principles in their conſtitutions, as direct them unerringly in all their ways. Beſides thoſe now mentioned, there are ſome other miſtakes and errors in this work on the ſubject under diſcuſſion. Theſe, however, with one exception, we ſhall paſs unnoticed. The error we mean, and which, indeed, is not peculiar to theſe writers, is their ſuppoſing, that the advocates of inſtinct deny reaſon altogether to the brutes. But this opinion is wholly groundleſs. That ſome animals diſplay wonderful ſagacity and docility, that they even reaſon on ſeveral occaſions, is, we think, clear from the moſt ſatisfactory evidence. We ſhall mention a few facts in ſupport of this opinion. On the northern coaſt of Ireland a friend of Dr. Darwin's ſaw above a hundred crows at once preying upon muſcles: each crow took a muſcle up into the air twenty or forty yards high, and let it fall upon the ſtones, and thus, by breaking the ſhell, got poſſeſſion of the animal. A few years ago there was ſhewn at Exeter Change, London, an old monkey, who having loſt his teeth, uſed, when nuts were preſented to him, to take a ſtone in his hand, and crack them with it one by one; thus, uſing means, like the crows in the preceding inſtance, to accompliſh his purpoſes as well as we do. We are told by Linnæus, that the martin dwells on the outſide of houſes in Europe under the eaves; and that, when it has built its neſt, the ſparrow frequently takes poſſeſſion of it. The martin, unable to diſlodge his intruding enemy, convokes his companions, ſome of whom guard the captive, whilſt others bring clay, completely cloſe up the entrance of the neſt, and then fly away, leaving the ſparrow to be ſuffocated,

cated, as the puniſhment due to his injuſtice and temerity. This fact is mentioned in the "Amuſement Philoſophique, &c." of Father Bougeant. There is alſo an inſtance of it in the "Gentleman's Magazine;" in which we find alſo ſome intereſting particulars concerning a raven kept, ſome years ago, at the Red Lion at Hungerford. The account is, however, too long to be tranſcribed, although very much to our preſent purpoſe. We recollect ſeeing, a few years ago, a very ſenſible cat, which, when out at night, would tap regularly at the windows, if the doors and ſhutters were cloſed; knowing by experience, that ſhe was often let in at the windows by day. And what is ſtill a better proof of her reaſoning and ſagacity, ſhe would always tap at the bed-room windows, when diſappointed at the others, or when the night was far advanced. A lady with whom we were acquainted, had a tame bird, which ſhe was in the habit of letting out of its cage about her room every day. One morning as it was picking up ſome crumbs of bread off the carpet, her cat, who always before ſhewed great kindneſs for the bird, ſeized it on a ſudden, and jumped, with it in her mouth, upon a table. The lady, alarmed for the fate of her favourite, on turning about, obſerved that the door had been left open, and that a ſtrange cat had juſt come into the room. After turning it out, her own cat came down from her place of ſafety, and dropped the bird, without injuring, if we may ſo expreſs it, a hair of its head. Cowper's beautiful little poem on the dog and the water lily, gives an amiable inſtance of the reaſoning of the lower animals, which has been ſo ſweetly, and yet with ſuch elegant ſimplicity, told in verſe, that we cannot think of melting it down into the languid coldneſs of proſe. When we ſee brutes thus uſing means to obtain their ends, as well as ourſelves, muſt we not conclude that they reaſon? When the cat watches for hours in ſilent expectation of her prey; when the hound traverſes a wide extent of country in the chace; when the meaneſt inſect that we tread on, drags its wounded frame to a ſafe retreat; they ſhew as much perſevering voluntarity as man can boaſt. No animal manducates its food, or laps its drink, from the mere pleaſure of the motions. It uſes them as means for an end; and if hunger and thirſt were not felt, they would be conſidered as labours, and would not be performed. "Animals (ſays profeſſor Stewart, nearly in the words of Mr. Hume,) are left to make ſome ſmall acquiſitions, by experience, as ſufficiently appears in certain tribes, from the ſagacity of the old, when contraſted with the ignorance of the young; and from the effects which may be produced on many of them, by diſcipline and education."—"It ſeems as evident to me," ſays Mr. Locke, "that ſome animals do, in certain inſtances, reaſon, as that they have ſenſe; but it is only in particular ideas, juſt as they receive them from the ſenſes. They are the beſt of them tied up within thoſe narrow bounds, and have not, as I think, the faculty to enlarge them, by any kind of abſtraction." The obſervations which Mr. Locke makes in this part of his work on the faculties of the brutes, as compared with our's, are in general very juſt and worthy of peruſal. But there are ſeveral facts, which our limits do not allow us to ſtate, from which it is evident that brutes on ſome occaſions exhibit proofs of the power of abſtraction. That an animal can be capable of gratitude and affection for its maſter, without reaſoning, can, we think, hardly be maintained. From the maſter's protection and kindneſs, it infers that it is under obligations to him, which it owes not to another. Before concluding our remarks on the reaſoning of animals, we may quote one inſtance of the affection of a dog, which we think has never been ſurpaſſed. And we do it the more readily, as the circumſtance has been very poetically deſcribed by an author, who, with all his great merits, ſeldom writes better than upon this occaſion. The inſtance to which we allude is very intereſting, from the incident to which it relates, the death of an unfortunate young gentleman of promiſing talents, who periſhed, by loſing his way, in the ſpring of 1805, on the mountain Hellvellyn. His remains were found three months afterwards, guarded ſtill by a terrier bitch, that had long been the companion of his ſolitary rambles. This laſt circumſtance in particular, is very finely alluded to by Mr. Scott, in his little piece on the ſubject, to which he has given the name of Hellvellyn. As the few inſtances now ſtated are ſufficient, and ſpeak fully for themſelves, we ſhall not add to the number, nor ſtop to make any comments upon them. But it has been aſked, if we allow reaſon to the lower animals, in what does the difference between them and man conſiſt? Do their faculties and our's differ in degree, or in kind? To this queſtion we have not the vanity of thinking that we are able to give a ſatisfactory anſwer; we may, however, offer a few remarks. We ſee that animals learn much from experience and obſervation as well as ourſelves. It is thus they learn the nature, or the properties, of the objects that ſurround them, ſuch as heights, depths, diſtances, &c. "A horſe that has been accuſtomed to the field, becomes acquainted with the proper height which he can leap, and will never attempt what exceeds his force and ability. An old greyhound will truſt the more fatiguing part of the chace to the younger, and will place himſelf ſo as to meet the hare in her doubles; nor are the conjectures which he forms on this occaſion, founded in any thing but his obſervation and experience." By training and education we can teach our domeſtic animals much more than they would ever learn, if left to themſelves and their own obſervation. If we put them in new ſituations, we ſee that their acquired knowledge is much increaſed and improved, and that by a proper and ſtrict diſcipline we can train them up to a mode of acting directly contrary to their inſtincts, or natural propenſities. If theſe obſervations be juſt, (and we cannot ſee how they can be queſtioned,) it follows, that in the lower animals inſtinct is ſuſceptible of very great and ſtriking modifications. To produce theſe, however, ſtrict culture and diſcipline are neceſſary; without which, we do not think, that their own experience and obſervation would ever teach them to deviate much from the line of acting chalked out to them by their inſtincts, or original propenſities. And accordingly we agree with a remark of Mr. Hume's, "that though animals learn many parts of their knowledge from obſervation, there are alſo many parts of it which they derive from the original hand of nature, which much exceed the ſhare of capacity they poſſeſs on ordinary occaſions, and in which they improve *little or nothing*, by the longeſt practice and experience." Yet, notwithſtanding this ſuſceptibility of improvement by culture and education in the lower animals, we can never obſerve in them any thing approaching to the knowledge and ſagacity of man. They do not, like him, heap obſervation upon obſervation, they do not improve by the experience of the paſt, nor manifeſt any indications of a regard to futurity; their manufactures are always ſtationary, and all their acquiſitions of knowledge periſh with the individual. They never learn the arts of man; for inſtance, though often as fond of artificial heat as we are, not one of them has been ever known to lay a piece of coal or of wood upon the fire to keep it from going out. All this may be owing to their want of language; but it ſeems ſtrange, that they poſſeſs not this art, as ſome of them ſeem to have organs of articulation, as perfect as our's. They uſe means, it is true, for obtaining their ends ſometimes; but theſe in general are very ſimple and obvious. They reaſon too on ſome occaſions; but the want of language, or of general ſigns, puts it out of their power to reaſon, but on particular facts. The powers of claſſifying objects, of abſtract reaſoning, of uſing artificial ſigns as inſtruments of thought and of mutual communication, ſeem to be almoſt altogether peculiar to man. From theſe conſiderations, and ſeveral others, relating both to the intellectual and moral faculties of man, as contraſted with thoſe of the lower animals, it has been inferred, that the regular chain of being every where elſe obſervable on our globe, fails entirely here, and that their faculties differ from our's, not in degree, but in kind.

Thus then we ſee, that animals perform certain operations that are neither *rational, habitual*, nor *mechanical;* and although it cannot be doubted but ſome of them reaſon in ſeveral inſtances, ſtill, even from the ſhort details now given, we cannot allow, that their natural operations are performed with a view to conſequences. Nor ought the effects of inſtinct, (the labours of birds and bees for inſtance) appear extraordinary to us, when we conſider what aſtoniſhing effects *habit*, which has been happily called "a ſecond nature," enables us to produce. For inſtance, we need go no farther than reading, writing, and playing upon muſical inſtruments, all of which we learn by great attention, pains, and ſtudy; and moſt of all, perhaps, correct and quick extemporary eloquence. And ſurely, when the effects of an acquired principle are ſo very uncommon, it cannot be deemed ſtrange, that an original principle of the conſtitution of animals ſhould perform works ſtill greater or more aſtoniſhing.

INSTITA, a word uſed by the chirurgical writers, for a fillet or other bandage of that kind; and by medicinal writers, for that ſort of flat worms bred in the inteſtines called by many the tape-worm, or flat worm.

INSTITUTE, NATIONAL, *of France*, was newly organized in purſuance of a decree of the French government, with the advice of the council of ſtate, as follows: I. It is now divided into four claſſes, *viz.* 1. Claſs of phyſical and mathematical ſciences. 2. Claſs of French language and literature. 3. Claſs of hiſtory and foreign literature. 4. Claſs of the fine arts.

The actual members and foreign aſſociates of the inſtitute, ſhall be divided into theſe four claſſes.

A committee of five members of the inſtitute, named by the Firſt Conſul, ſhall adjuſt this diviſion, which ſhall be ſubmitted to the approbation of government.

II. The firſt claſs ſhall be formed of the ten ſections which at preſent compoſe the firſt claſs of the inſtitute, with a new ſection of geography and navigation, and eight foreign aſſociates.

The ſections ſhall be compoſed and called as follows:

Mathematical Sciences.	Geometry - - - - - -	6 members.
	Mechanics - - - - - -	6 ditto.
	Aſtronomy - - - - - -	6 ditto.
	Geography and Navigation -	3 ditto.
	General Phyſics - - - -	6 ditto.
Phyſical Sciences.	Chemiſtry - - - - - -	6 members.
	Mineralogy - - - - - -	6 ditto.
	Botany - - - - - - -	6 ditto.
	Rural Economy and Veterinary Art - - - - - - -	6 ditto.
	Anatomy and Zoology - -	6 ditto.
	Medicine and Surgery - -	6 ditto.

The firſt claſs ſhall appoint, with the approbation of the Firſt Conſul, two perpetual ſecretaries, one for the mathematical ſciences, the other for the phyſical ſciences. The perpetual ſecretaries ſhall be members of the claſs, but ſhall not form a part of any ſection.

The firſt claſs may elect ſix of its members from the other claſſes of the inſtitute.

It may name an hundred correſpondents ſelected from the learned men of France and foreign countries.

III. The ſecond claſs ſhall be compoſed of forty members.

It is particularly charged with the compoſition of the dictionary of the French language. It ſhall examine, with reſpect to language, the important works of literature, hiſtory, and the ſciences. The collection of its critical obſervations ſhall be publiſhed at leaſt, four times in a year.

It ſhall name from its own body, and with the approbation of the Firſt Conſul, a perpetual ſecretary, who ſhall continue to be of the number of the forty members which compoſe it.

It may elect twelve of its members from the other claſſes of the inſtitute.

IV. The third claſs ſhall be compoſed of forty members and eight foreign aſſociates.

The object of its reſearches and labours ſhall be learned languages; antiquities and monuments; hiſtory, and all the moral and political ſciences connected with hiſtory. It ſhall particularly apply itſelf to the enriching of French literature with the works of Greek, Latin, and Oriental authors, which have not yet been tranſlated.

It ſhall employ itſelf in the continuation of diplomatic collections.

It ſhall name from its own body, under the approbation of the Firſt Conſul, a perpetual ſecretary, who ſhall be of the number of the forty members which compoſe the claſs.

It may elect nine of its members from the other claſſes of the inſtitute.

It may name ſixty correſpondents, natives or foreigners.

V. The fourth claſs ſhall be compoſed of twenty-eight members and eight foreign aſſociates.

They ſhall be divided into ſections, deſcribed and formed as follows:

Painting - - - - -	10 members.
Sculpture - - - - -	6 ditto.
Architecture - - - -	6 ditto.
Engraving - - - - -	3 ditto.
Muſic (compoſition) - - -	3 ditto.

It ſhall appoint, with the approbation of the Firſt Conſul, a perpetual ſecretary, who ſhall be a member of the claſs, but ſhall not be a part of a ſection.

It may elect ſix of its members from the other claſſes of the inſtitute.

It may name thirty-ſix correſpondents, national or foreign.

VI. The foreign aſſociated members ſhall have a deliberative voice only on ſubjects of ſcience, literature, and the arts; they ſhall not form part of any ſection, nor interfere in any uſage.

VII. The preſent actual national aſſociates of the inſtitute ſhall form part of the one hundred and ninety-ſix correſpondents attached to the claſſes of the ſciences, belles lettres, and fine arts.

Correſpondents may not aſſume the title of members of the inſtitute.

They ſhall loſe that of correſpondent when they ſhall be domiciliated at Paris.

VIII. Nominations to vacant places ſhall be made by each claſs in which the vacancy happens; the perſons elected ſhall be confirmed by the Firſt Conſul.

IX. The members of the four claſſes ſhall enjoy a reciprocal.

cal right to aſſiſt at the particular ſittings of each claſs, and may deliver lectures when they are requeſted.

They ſhall re-unite four times in a year into one body, to communicate their proceedings.

They ſhall elect in common the librarian and under librarian of the inſtitute, as well as all thoſe agents who belong to the inſtitute in common.

Each claſs ſhall preſent for the approbation of the government, the particular ſtatutes and regulations of its internal police.

X. Each claſs ſhall hold one public ſitting every year, at which the other three ſhall aſſiſt.

XI. The inſtitute ſhall receive annually from the public treaſury 1500 fr. for each of its non-aſſociated members, 6000 fr. for each of its perpetual ſecretaries; and for its expences, a ſum which ſhall be fixed every year, upon the demand of the inſtitute, and compriſed in the eſtimates of the miniſter of the interior.

XII. There ſhall be an adminiſtrative committee of the inſtitute, compoſed of five members, two from the firſt claſs, and one from each of the others, named by their reſpective claſſes.

This committee ſhall regulate in the general ſittings preſcribed by art. IX. all that relates to the adminiſtration, to the general expences of the inſtitute, and to the diviſion of its funds between the four claſſes.

Each claſs ſhall afterwards regulate the application of the funds aſſigned to it for its expences, as well as all that concerns the printing and publiſhing its memoirs.

XIII. Every year the claſſes ſhall diſtribute prizes, the number and value of which ſhall be regulated as follows:

The firſt claſs, a prize of 3000 francs.

The ſecond and third claſs, each a prize of 1500 francs.

The fourth claſs, grand prizes of painting, ſculpture, architecture, and muſical compoſition. Thoſe who ſhall have gained one of the grand prizes ſhall be ſent to Rome, and maintained at the expence of government.

The above decree was followed by a ſecond, appointing the members of the different claſſes, and regulating the days of their meeting.

The ſittings of the firſt claſs are to be held every Monday; thoſe of the ſecond claſs every Wedneſday; thoſe of the third every Friday, and thoſe of the fourth every Saturday.

Theſe ſittings are to be held in the ſame place, and to laſt from three o'clock till five.

INSTITUTES, *Inſtituta*, in the *Civil Law*, a book, containing the elements, or principles of the Roman law; and which conſtitutes the laſt part of the *corpus juris civilis*.

The inſtitutes are a compendium, or ſummary of the whole body of civil law, in four books, compoſed by Tribonianus, Theophilus, and Dorotheus, by order of the emperor Juſtinian, for the uſe of young ſtudents; who, having the firſt elements of the whole profeſſion in this little treatiſe, might the ſooner gain a competent knowledge of it without being diſcouraged by the bulk of the other books.

Theſe inſtitutes proceed, with no contemptible method, from I. "Perſons" to II. "Things;" and from things to III. Actions;" and the article IV. of "Private Wrongs" is terminated by the principles of "Criminal Law." For an abridged account of theſe inſtitutes, ſee Gibbon's Decl. and Fall of the Roman Empire, vol. vii. See alſo CIVIL *Law*

INSTITUTES likewiſe denote a ſyſtem of law, or rules in any ſcience.

INSTITUTION, in a general ſenſe, the act of ordaining, founding, or eſtabliſhing any thing.

Thus we ſay, Moſes inſtituted the ceremonies of the old law; Jeſus Chriſt inſtituted the ſacraments of the new.

INSTITUTION, in the *Canon* and *Common Law*, is the act of the biſhop, or of one commiſſioned by him, whereby a clerk, after the patron's preſentation has been admitted, is inveſted with the ſpiritualities of a rectory, or vicarage: for by inſtitution the care of the ſouls of the pariſh is committed to his charge. See PRESENTATION.

The clerk kneels down before the biſhop, whilſt he pronounces theſe words of inſtitution (inſtituo te rectorem eccleſiæ de A. B. cum cura animarum, & accipe curam tuam & meam); and the clerk holds the written inſtrument, with the epiſcopal ſeal annexed, in his hand, during the ceremony.

Before the clerk is inſtituted, he muſt ſubſcribe the thirty-nine articles of religion, in the preſence of the ordinary, or his ſubſtitute; and this ſubſcription muſt be without reſerve, exception, or qualification; elſe his inſtitution is, *ipſo facto*, void and null, and the church ſtill vacant. 13 Eliz. c. 12.— At the ſame time the ordinary requires the clerk to ſubſcribe the other two articles mentioned in the 36th canon about the king's ſupremacy, and the lawfulneſs and uſe of the liturgy: the clerk muſt alſo, before inſtitution, ſubſcribe to that part of the declaration enjoined by the act of uniformity, 14 Car. II. c. 24, *viz.* "I will conform to the Liturgy of England, as by law eſtabliſhed." – Before inſtitution, he muſt alſo take the oaths mentioned in the firſt ſtatute of William and Mary, c. 8. inſtead of the former oaths of allegiance and ſupremacy, required by ſtat. 1 Eliz. and then he muſt take the oath againſt ſimony, enjoined by the 40th canon, and the oath of canonical obedience; and if it is a vicarage, the oath of perſonal reſidence; and he is to have certificates given him of his ſubſcribing the declaration contained in the act of uniformity, in Engliſh, in a diſtinct inſtrument, under the hand and ſeal of the biſhop; and of his other ſubſcriptions and oaths, in Latin.

The clerk ought by all means to have witneſſes of his inſtitution, his taking the oaths, making ſubſcriptions, &c. and therefore he ſhould make ſome preſent to write their names on the back of his inſtruments, and make memorandums who they are, and where they live.

The church, by inſtitution, is full againſt all perſons but the king, but it is not full againſt the king, till induction; and the clerk by it may enter upon the parſonage houſe and glebe, and take the tithes; but he cannot let or grant them, nor ſue for them, if they be refuſed to be paid till he be inducted.

After inſtitution, the clerk is to receive a written mandate from the ordinary to the archdeacon, or other proper perſon, in order to his induction; without which he has not a full right to his temporalities, unleſs the benefice be a donative. See INDUCTION.

INSTITUTION, *African*, a ſociety formed by the friends of the Abolition of the Slave-trade aſſembled on the 14th of April 1807, and eſtabliſhed on the ſubſequent 15th of July. The reſolutions adopted by the conſtituent meeting, as the baſis of the aſſociation, are as follow: 1. That this meeting is deeply impreſſed with a ſenſe of the enormous wrongs which the natives of Africa have ſuffered in their intercourſe with Europe; and from a deſire to repair thoſe wrongs, as well as from general feelings of benevolence, is anxious to adopt ſuch meaſures as are beſt calculated to promote their civilization and happineſs. 2. That the approaching ceſſation of the ſlave-trade, hitherto carried on by Great Britain, America, and Denmark, will, in a conſiderable degree,

gree, remove the barrier which has ſo long obſtructed the natural courſe of ſocial improvement in Africa; and that the way will thereby be opened for introducing the comforts and arts of a more civilized ſtate of ſociety. 3. That the happieſt effects may be reaſonably anticipated from diffuſing uſeful knowledge, and exciting induſtry among the inhabitants of Africa, and from obtaining and circulating throughout this country more ample and authentic information concerning the agricultural and commercial faculties of that vaſt continent; and that through the judicious proſecution of theſe benevolent endeavours, we may ultimately look forward to the eſtabliſhment, in the room of that traffic, by which Africa has been ſo long degraded, of a legitimate and far more extended commerce, beneficial alike to the natives of Africa, and to the manufacturers of Great Britain and Ireland. 4. That the preſent period is eminently fitted for proſecuting theſe benevolent deſigns; ſince the ſuſpenſion, during the war, of that large ſhare of the Slave-trade, which has commonly been carried on by France, Spain, and Holland, will, when combined with the effect of the Abolition laws of Great Britain, America, and Denmark, produce nearly the entire ceſſation of that traffic along a line of coaſt extending between two and three thouſand miles in length, and thereby afford a peculiarly favourable opportunity for giving a new direction to the induſtry and commerce of Africa. 5. That, for theſe purpoſes, a ſociety be immediately formed, to be called the "African Inſtitution." See the firſt report of the ſociety, which proceeds to obviate the difficulties which may appear to lie in the way of the attainment of theſe intereſting objects; and particularly to remove the moſt ſpecious objection to the deſign, *viz.* deſpair of its ſucceſs. The means by which this laudable aſſociation purpoſed to accompliſh its noble and captivating objects are as follow: Firſt of all, this inſtitution, wiſe by the example of the Sierra Leone company, diſclaims in the outſet all projects of a colonial or commercial nature. It embarraſſes itſelf with no concerns of government—no mercantile ſpeculations—no factories or forts—not even with the poſſeſſion of a ſingle ſhip, or an acre of ground. This clears the way for exertion, not only by removing every ſuſpicion of unworthy or doubtful motives, but by throwing off a thouſand clogs which muſt have hampered an eſtabliſhment of a different character. For obvious reaſons the ſociety alſo diſclaims all ſchemes of religious miſſion; and avowing, upon that important ſubject, not certainly any kind of indifference, but a wiſe and neceſſary neutrality, it leaves in other hands the taſk of propagating the goſpel among the Africans, and confines its own exertions to the introduction of that civilization, which is the beſt preparative for the truths of Chriſtianity. Not to mention other reaſons for this ſalutary caution, it has one moſt important and beneficial effect. It opens wide the doors of the inſtitution to all ſects and denominations of Chriſtians,—whom it thus invites to co-operate for purpoſes equally ſubſervient to every form of worſhip, and every modification of religious belief. The means which it is propoſed by this ſociety to employ for the purpoſe of promoting civilization and improvement in Africa, are of the following kind: "1. To collect and diffuſe throughout this country accurate information reſpecting the natural productions of Africa, and, in general, reſpecting the agricultural and commercial capacities of the African continent, and the intellectual, moral, and political condition of its inhabitants. 2. To promote the inſtruction of the Africans in letters and in uſeful knowledge, and to cultivate a friendly connection with the natives of that continent. 3. To endeavour to enlighten the minds of the Africans with reſpect to their true intereſts; and to diffuſe information amongſt them reſpecting the means whereby they may improve the preſent opportunity of ſubſtituting a beneficial commerce in place of the ſlave-trade. 4. To introduce amongſt them ſuch of the improvements and uſeful arts of Europe, as are ſuited to their condition. 5. To promote the cultivation of the African ſoil, not only by exciting and directing the induſtry of the natives, but by furniſhing, where it may appear advantageous to do ſo, uſeful ſeeds and plants, and implements of huſbandry. 6. To introduce amongſt the inhabitants beneficial medical diſcoveries. 7. To obtain a knowledge of the principal languages of Africa, and, as has already been found to be practicable, to reduce them to writing, with a view to facilitate the diffuſion of information among the natives of that country. 8. To employ ſuitable agents, and to eſtabliſh correſpondences, as ſhall appear adviſable; and to encourage and reward individual enterpriſe and exertion in promoting any of the purpoſes of the inſtitution."—Firſt Report. Beſides, the ſociety has adopted from the beginning, and ſince ſteadily purſued, the reſolution of watching over the ſtrict execution of the abolition laws—of procuring all information reſpecting the evaſion or breach of thoſe laws, which daring ſpeculators may attempt—of keeping the attention of the government alive, and quickening the exertions of the crown-officers on thoſe points—of ſuggeſting, from time to time, ſuch improvements in thoſe laws as a practical experience of their imperfections, or the change of circumſtances, may point out;—and, finally, of promoting, as far as poſſible, by communicating information, and other appropriate methods, the abolition of the African Slave-trade in foreign countries. This latter ſervice is quite eſſential to the improvement of Africa; and it is ſuch as a body, like the African inſtitution, is well adapted to perform. The preſident of the African Inſtitution is the duke of Glouceſter; and of the directors, who chiefly carried on its ordinary buſineſs along with this diſtinguiſhed prince, we ſhall only mention the names of Meſſrs. Wilberforce, Thornton, Vanſittart, W. Smith, Brougham, Clarkſon, G. Sharp, Allen, Stephen, and Macaulay, who, much to the advantage of the ſociety, undertook the laborious and difficult office of ſecretary, until it could be filled by a permanent arrangement. A reſpectable ſubſcription of about 3000*l.* was immediately raiſed. At the end of 1808, this had increaſed to 4374*l.*, of which 531*l.* aroſe from annual ſubſcriptions. Since that time the funds have been augmented by many donations, and the liſt of annual contributors ſoon increaſed. For a further account of this inſtitution, we refer to its annual reports, and to the Edinburgh Review, No. 30.

INSTITUTIONS, in *Literary Matters*, denote a ſyſtem of the elements, or rules, of any art or ſcience. Such are inſtitutions of medicine, inſtitutions of rhetoric, &c.

INSTITUTORES, in *Botany*, that ſet of authors in this ſcience who have laid down certain ſettled rules, axioms, and inſtitutions in it.

INSTRUCTIVE COLUMN. See COLUMN.

INSTRUMENT denotes a thing which is ſubſervient to a cauſe for producing its effect.

A common caſe of mathematical inſtruments contains ſeveral compaſſes, a ſector, ſcale, drawing-pen, and protractor. A caſe of ſurgeon's inſtruments for the pocket contains different ſized lancets, ſciſſors of ſeveral kinds, plain and toothed forceps, ſtraight and crooked inciſion-knives, a ſpatula, probes, needles, &c. Aſtronomical inſtruments, are the teleſcope, quadrant, &c. Chemical inſtruments, ſee LABORATORY. For the method of dividing mathematical and aſtronomical inſtruments, ſee ENGINE and GRADUATION.

INSTRUMENTS *of Sacrifice*, in the *Antique Architecture*, are ornaments, as vaſes, pateræ, candleſticks, knives, &c. wherewith the victims were killed, &c. inſtances of which we ſee in a Corinthian frieze in the remains of a temple behind the Capitol at Rome, &c.

INSTRUMENT is alſo uſed, in *Law*, to ſignify ſome public act, or authentic deed, by means whereof any truth is made apparent, or any right or title eſtabliſhed, in a court of juſtice.

INSTRUMENT, primarily denoting writing, charter, or record, is ſometimes uſed by Latin writers for the Old and New Teſtament. It occurs ſeveral times in Tertullian, reckoned the moſt ancient Latin writer of the church now remaining. He calls the Goſpels, or the New Teſtament in general, the Evangelic Inſtrument, and ſays, "how large chaſms Marcion has made in the epiſtle to the Romans, by leaving out what he pleaſes, may appear from one entire Inſtrument," or one unaltered copy of the New Teſtament, particularly of that epiſtle. Speaking of the ſhepherd of Hermas, he ſays, it was not reckoned a part of the Divine Inſtrument; thereby meaning, as it ſeems, the New Teſtament. He calls the law and the prophets the Jewiſh inſtruments, that is, writings or ſcriptures. He ſpeaks of the antiquity of the Jewiſh inſtruments, or ſcriptures. He ſeems in one place (Apol. cap. 18.) to uſe the word inſtrument as equivalent to ſcriptures, containing the doctrine of revelation, or the revealed will of God. Lardner.

INSTRUMENT, in *Muſic*, is a generical term, under which all artificial bodies, capable of producing and varying muſical ſounds in imitation of the voice, are comprehended. Every body capable of agitating the air by ſome ſhock, and exciting by its vibrations in this agitated ſtate undulations ſufficiently frequent, may produce ſound; and all bodies capable of accelerating or retarding theſe undulations may vary their ſounds. See SOUNDS.

There are three ways of producing ſound by inſtruments: by the vibration of ſtrings, by the vibration of elaſtic bodies, and by the colliſion of air incloſed in pipes. The invention of theſe inſtruments will be conſidered at the word MUSIC.

Inſtruments are generally claſſed under the three following heads; ſtringed-inſtruments, wind-inſtruments, and inſtruments of percuſſion. The ſtringed-inſtruments of the ancients were very numerous. Thoſe moſt known were the following: the lyra, pſalterium, trigonum, ſambuca, cithera, pectis, magadis, barbiton, teſtudo, epigonium, ſimmicum, epandoron, &c. All theſe inſtruments were touched with the fingers or played with a plectrum.

Their principal wind-inſtruments were the tibia, fiſtula, tuba, cornu, lituus, hydraulicon, &c.

Their inſtruments of percuſſion were the tympanum, cymbalum, crepitaculum, tintinnabulum, crotalum, &c; but many of theſe are monotonous, and only render one ſound.

Of moſt of theſe ancient inſtruments repreſentations on plates have been given (Hiſt. Muſ. vol. i.) from drawings made at Rome under our own eye, and under the guidance of Piraneſi, and Meſſrs. Jenkins, Morriſon and Byers, the beſt antiquaries at Rome in 1770; with a deſcription and authorities for their local ſituation at the time.

The beſt books on the ſubject of ancient muſical inſtruments, and the moſt worthy of being conſulted, are Blanchini de Tribus Generibus Inſtrumentorum Veterum Organica; Gabinetto Armonica, del Bonanni; Bartolinus de Tibiis Veterum; and Eſſais ſur la Muſique par M. Laborde; who has given repreſentations very neatly engraved of the muſical inſtruments during the middle and lower ages, from illuminations in ancient MSS. of the Bibl. Royale at Paris in 1780; which, if the wiſh to render their delineation pictureſque had not a little injured their fidelity, would be invaluable.

INSTRUMENTS, *Muſical*, of the Abyſſinians, from Mr. Bruce, the authenticity of whoſe account ſeems to be no longer doubted, we ſhall give from his letter inſerted in Burney's General Hiſtory of Muſic, vol. i.

"There are ſix muſical inſtruments known in Abyſſinia; the flute, the trumpet, the kettle-drum, the tambourine, the ſiſtrum, and the lyre.

"The four firſt are uſed in war, and are by much the moſt common; the fifth is dedicated to the ſervice of the church; and the ſixth is peculiarly an attendant on feſtivity and rejoicings.

"There are two principal languages in Abyſſinia, the Æthiopic, which is the literal, or dead language; and the Amharic, or language of Amhara, ſpoken by the court.

"The flute, in the Æthiopic, is called *Kwetz*, a word difficult to be written or ſounded in Engliſh; in the Amharic, it is called Agădă: it is about the ſhape and ſize of the German flute, but played upon long-ways, with a mouth-piece reſembling that of the clarinet; its tone is not loud, but accompanied with a kind of jar, like a broken hautbois; not owing to any accidental defect, but to conſtruction and deſign, as it would not be eſteemed without it.

"The kettle-drum is called in both languages *Nagareet*, becauſe all proclamations are made by the ſound of this drum (theſe are called Năgăr), if made by governors, they have the force of laws in their provinces; but if made by the king, they are for all Abyſſinia. The kettle-drum is a mark of ſovereign power: whenever the king promotes a ſubject to be governor, or his lieutenant-general in a province, he gives him a kettle-drum, and ſtandard as his inveſtiture. The king has forty-five of theſe drums always beating before him when he marches. They are in ſhape and ſize like our's, only they are braced very diſadvantageouſly; for the ſkin is ſtrained over the outer rim, or lip of the drum, and brought a third down its outſide, which deadens it exceedingly, and deprives it of that clear, metallic ſound which our's has. Each man has but a ſingle drum, upon the left ſide of his mule, and beats it with a crooked ſtick, about three feet long. Upon the whole, its ſound is not diſagreeable, and I have heard it at an incredible diſtance.

"The third inſtrument is the ſmall drum, called Kăbăro, in Æthiopic and Amharic; though in ſome parts of Amhara it is alſo called Hătămo. It is about half the diameter, and twice the length of our common drum; it is juſt the tambourine of Provence, only rounded to a point at the lower end. This is beaten always with the hand, and carried ſometimes on foot, ſometimes on horſeback, when any inferior officer (not having a Nagareet) marches.

"The trumpet is called Mĕlĕkēta, or Mĕlĕket; and *Kenet* in Amharic, but *Keren* in Æthiopic (or horn); which ſhews of what materials it was anciently formed. It is now made of a cane that has leſs than half an inch aperture, and about five feet four inches in length. To this long ſtalk is fixed at the end a round piece of the neck of a gourd, which has juſt the form of the round end of our trumpet, and is on the outſide ornamented with ſmall white ſhells; it is all covered over with parchment, and is a very neat inſtrument. This trumpet ſounds only one note, E, in a loud, hoarſe, and terrible tone. It is played ſlow when on a march, or before an enemy appears in ſight; but afterwards it is repeated very quick, and with great violence, and has the effect upon the Abyſſinian ſoldiers of tranſporting them abſolutely to fury and madneſs, and of making them ſo regardleſs of life, as to throw themſelves in the middle of the enemy, which they do with great gallantry. I have often in time of peace tried what effect this charge would have upon them, and found that none who heard it could continue ſeated, but that all roſe up and continued the whole time in motion.

"The fifth inſtrument is the ſiſtrum: it is uſed in the quick meaſure, or in allegros, in ſinging pſalms of thankſgiving. Each prieſt has a ſiſtrum which he ſhakes in a very threatening manner at his neighbour, dancing, leaping, and turning round with ſuch an indecent violence, that he reſembles rather a prieſt of paganiſm, whence this inſtrument was derived, than a Chriſtian. I have forgot the name of the ſiſtrum in Ethiopic, but on looking into my notes I ſhall find it.

"The ſixth and laſt inſtrument is the lyre, which is never played ſolo, but always in accompanying the voice, with which it plays conſtantly in uniſon; nor did I ever hear *muſic in parts*, in any nation, ſavage or poliſhed, out of Europe: this is the laſt refinement muſic received, after it was in poſſeſſion of complete inſtruments, and it received it probably in Italy.

"The lyre has ſometimes five, ſometimes ſix, but moſt frequently ſeven ſtrings, made of the thongs of raw ſheep or goat ſkins, cut extremely fine, and twiſted; they rot ſoon, are very ſubject to break in dry weather, and have ſcarce any ſound in wet. From the idea, however, of this inſtrument being to accompany and ſuſtain a voice, one would think that it was better mounted formerly.

"The Abyſſinians have a tradition, that the ſiſtrum, lyre, and tambourine were brought from Egypt into Æthiopia, by Thot, in the very firſt ages of the world. The flute, kettle-drum, and trumpet, they ſay, were brought from Paleſtine with Menelek, the ſon of their queen of Saba, by Solomon, who was their firſt Jewiſh king.

"The lyre in Amharic is called bĕg (the ſheep); in Ethiopic, it is called mĕsīnkō; the verb *ſinko* ſignifies to ſtrike ſtrings with the fingers: no *plectrum* is ever uſed in Abyſſinia, ſo that *meſinko* being literally interpreted, will ſignify "the ſtringed inſtrument played upon with the fingers." This would ſeem as if anciently there was no other ſtringed inſtrument in Abyſſinia, nor is there any other ſtill." See THEBAN HARP, with Mr. Bruce's drawing and account of it, in the ſame volume.

Modern muſical inſtruments will be deſcribed under their ſeveral heads as they occur.

In modern times, ſince harmony has ſuſtained ſo important a part in muſic, muſical inſtruments have been divided into *perfect* and *imperfect*, the firſt of theſe being ſuch as are capable of executing or ſounding as many notes of different pitches within a given compaſs, as within an octave for inſtance, as the harmony of the muſic performed upon it may require, without being forced to introduce notes, which make falſe or tempered intervals, or *wolves* with the other notes of the piece, ſounded at the ſame time; as in the ſecond claſs neceſſarily happens, in very numerous inſtances, where the notes are previouſly fixed and tuned, as it is called, to ſome certain ſcale or ſyſtem of 12 notes within the octave, and which notes the performer of any one part in a piece of muſic has not the power of altering and adjuſting to the true harmonic relation with the ſimultaneous notes of the baſs, or other principal part: imperfect inſtruments are not, however, confined to thoſe with 12 ſtrings, pipes, &c. in an octave, but the term applies, though in a leſs degree, to inſtruments with 14, 16, or 17 ſtrings, as ſhewn in our article HAWKE'S *temperament* of the muſical ſcale, where his 17 notes in the octave are proved to be incapable of baniſhing wolves, or falſe intervals, even from tempered ſyſtems, and which Dr. Smith's harpſichords with 21 notes in the octave were alike unable to effect, in the numerous paſſages of modern muſic where double ſharps or double flats occur: but on the improved organs and piano fortes of D. Loeſchman, whoſe ſcale is extended to 24 notes, all ſuch notes as uſually occur can be truly given, according to any aſſigned ſyſtem of temperament. The violin, viola, baſs-viol or violoncello, and double baſs, have held a diſtinguiſhed rank in modern refined concerts as perfect inſtruments, and were, indeed, the only inſtruments that ſhould be admitted to accompany the human voice, which exceeds, in the perfection of its ſcale, any inſtrument whatever, ſince a vocal performer, with a good ear and intonation, can inſtantly ſtrike a perfect interval to any note whatever, without the leaſt beating or degree of temperament or imperfection in the harmony, and this he does, by attempering the leaps or intervals of the melody (ſee MELODY, *Temperaments of*): it being abſolutely and demonſtrably impoſſible to avoid temperaments, or the uſe of imperfect intervals, either in the harmony or in the melody, (but they need not be uſed in both,) on perfect inſtruments, as on imperfect inſtruments they neceſſarily muſt, as is ſhewn in our article HARMONY, *Temperaments of*: the late Mr. Maxwell, in the year 1781, in his "Eſſay on Tune," ſketched out the principles of an organ capable, by means of 44 pipes in each octave, of entirely baniſhing temperaments from the harmony, in 24 keys, 12 major and 12 minor: but we never heard until very lately, that any one had conſtructed ſuch an inſtrument. It appears, however, that on the 3d of July 1810 the Rev. Henry Liſton took out a patent for his *enharmonic organ*, and in the autumn of the year iſſued propoſals for publiſhing, by ſubſcription, "An Eſſay on perfect Intonation," and for exhibiting one of theſe patent organs in London, which had been completed in Scotland, and tuned, ſays his proſpectus, "perfectly true throughout, *without any temperament whatever*, and performs every chord, in every key *abſolutely perfect*, nor is there any combination which it is not capable of performing."—"The decided ſuperiority of the harmony has been acknowledged by the beſt judges, and the performers have found no ſerious difficulty in the moſt ſudden and extraneous modulation, or in the wideſt range of keys:" ſuch were the pretenſions of this inſtrument, and which no muſical perſons that we converſed or correſponded with ſeemed diſpoſed to expect would be realiſed: however, in the beginning of this month (April 1811), Mr. Liſton arrived in London with his organ, and had it put up at Flight and Robſon's, organ builders in St. Martin's lane, and tuned it, and on the 16th politely gave us the opportunity to be the firſt that heard it performed on in London, and of hearing the effect of ſome glees ſung to it; which proved delightful indeed, and rather exceeded our expectations than otherwiſe, though they had, as above hinted, been raiſed above thoſe of moſt muſical perſons. The Rev. Mr. Liſton alſo favoured us with the peruſal of the manuſcript of the firſt part of his intended work, in which we were delighted to obſerve, that a good knowledge and a correct application of mathematics is combined with a thorough knowledge of compoſition, and of the wants of the practical muſician; the defect of one of which eſſential qualifications we have ſo often had to deplore, and even to reprobate, in our numerous quotations and references to modern writings on temperament, and on the nature and magnitude of muſical intervals, in the different articles of our work. Mr. Liſton's work will deſcribe an inſtrument with 24 pipes in each octave, and to each of which two valves or ſhaders, of different ſizes, are adapted, affixed to radii from rolls or axles, that can be turned by means of pedals, ſo that each of theſe pipes can be made to ſound one major comma or two major commas flatter than the pitch of the pipe, making in all 72 ſounds in each octave, which, by the 12 uſual finger keys and the uſe of twelve pedals, enables the performer to give 33 perfect keys, without any tempered harmonies. The inſtrument, ſhewn as above, has not ♭ F, but contains 20 pipes, and gives 60 different ſounds within the octave. See the Philoſophical Magazine, vol. xxxvii. p. 273, and our article Liston's *Scales of Muſical Intervals*.

Instrument, *Wind*. See Wind.

INSTRUMENTAL Arithmetic. See Arithmetic.

Instrumental *Cauſe*. See Cause.

INSTRUMENTUM Synodale. See Synodale.

INSUFFLATIO, a term uſed by ſome writers in medicine, to expreſs the blowing into any part, in order to convey the fumes of medicine into it.

INSULATE, or Insulated, a term applied to a column or other edifice, which ſtands alone, or free and detached from any contiguous wall, &c. like an iſland in the ſea; whence the denomination is apparently derived.

Insulated, in *Electricity*, is a term applied to bodies that are ſupported by electrics or non-conductors; ſo that their communication with the earth, by conducting ſubſtances, is interrupted.

INSULT, in *Law*. See Assault.

Insult, a military term uſed for the attack of any poſt with open force: without the apparatus of trenches, ſaps, or any regular approaches. See Assault.

INSULTUS, a word uſed by the writers in medicine to ſignify the acceſs of the paroxyſm in intermittent diſeaſes, or ſometimes the firſt invaſion of a diſeaſe.

INSUMA, in *Geography*, a town of Arabia, in the province of Hedsjas; 10 miles S.W. of Mecca.

INSUPER, a word uſed by the auditors of the Exchequer. In their accompts they ſay, ſo much remains *inſuper* to ſuch an accomptant; that is, ſo much remains due on his accompt.

INSURANCE, or Assurance, in *Law* and *Commerce*, a contract or agreement whereby one party, in conſideration of a ſtipulated ſum, undertakes to indemnify the other, againſt certain perils or riſks to which he is expoſed, or againſt the happening of ſome event. The party, who takes upon himſelf the riſk, is called the "Inſurer," ſometimes the "Underwriter," from his ſubſcribing his name at the foot of the policy; the party protected by the inſurance is called the "inſured;" the ſum paid to the inſurer, as the price of the riſk, is called the "premium;" and the written inſtrument, in which the contract is ſet forth and reduced to form, is called a "policy of inſurance, or aſſurance." See Policy.

The riſks againſt which inſurances are made are infinitely various, and many frauds have been practiſed on the ignorant and credulous, under pretence of inſurance, which the legiſlature has found it neceſſary, from time to time, to repreſs. In the reign of queen Anne, ſeveral offices were opened for making inſurances on marriages, births, chriſtenings, ſervice, &c., and fraudulent practices prevailed to ſuch a degree, that by ſtat. 9 Ann. c. 6. § 37, a penalty of 500*l*. is impoſed on every perſon ſetting up ſuch office, and 100*l*. on every perſon making ſuch aſſurances in any office already ſet up. Fraudulent inſurances have alſo occurred among dealers in lottery tickets, the ſhares and the chances of them, which, beſides the reſtraints to which they are ſubject in the annual lottery acts, have occaſioned the ſtat. 27 Geo. III. c. 1, made expreſsly with a view to this evil, and by which they have been conſiderably diminiſhed. See Lottery.

Inſurances of the greateſt public utility are, "Marine Inſurances," including bottomry and reſpondentia, which are a ſpecies of marine inſurance (ſee each of theſe articles);—"Inſurance upon Lives" (ſee Assurance); and "Inſurances againſt Loſſes by Fire."

Insurances, *Marine*, are made for the protection of perſons having an intereſt in ſhips, or goods on board, from the loſs or damage that may happen to them from the perils of the ſea, during a certain voyage, or a fixed period of time. By "peril" is here meant, not danger or hazard, according to the common acceptation of the term; but it ſignifies the "happening" of the event or misfortune of which danger was apprehended. The utility of this contract conſiſts in the protection it affords to maritime commerce, by dividing loſſes, when they happen, between many, ſo as to make them fall leſs heavily on individuals, who are thus enabled to embark their whole capitals in hazardous enterpriſes. (See the preamble to the ſtat. 43 Eliz. c. 12.) As the Turks are unacquainted with inſurance, they require for the loan of money 15 or 20 *per cent.*; and when they lend money to merchants who trade by ſea, they charge 30 *per cent.* Some have aſcribed the invention of inſurance to the ancient Romans. Accordingly Puffendorf, Barbeyrac, Loccenius, Kulpis, and others, refer to a paſſage in Livy (l. xxiii. c 44.), who ſays, that when the Roman army in Spain was diſtreſſed for proviſions, cloathing, and other neceſſaries, a company engaged to convey to them every thing of which they ſtood in need, under this ſtipulation, that the ſtate ſhould make good their loſs, in caſe their veſſels ſhould be ſhipwrecked by ſtorms, or taken by the enemy. This was undoubtedly a promiſe of indemnification, but by no means an inſurance, in which it is always neceſſary to give a premium. Kulpis, Anderſon, Malyne, and others, rely on the authority of Suetonius (l. v. c. 18.) who tells us, that the emperor Claudius promiſed to indemnify merchants for their loſſes, if their ſhips ſhould periſh by ſtorms at ſea; but neither this paſſage nor another that has been referred to in Valerius Maximus (l. vi. c. 5.), contains any thing that can be applied to inſurance in the modern ſenſe of the term. A paſſage has alſo been quoted by Grotius from Cicero's epiſtles (Epiſt. ad Fam. ii. ep. 7.), as a proof that the Romans were acquainted with this contract. But Cicero's words, juſtly interpreted, ſeem to bear a much ſtronger alluſion to the practice of remitting money by means of bills of exchange, than to that of inſuring againſt the perils of the ſea. In the Pandects we have an obſervation of Ulpian, which affords greater reaſon for ſuppoſing that the contract of inſurance was not altogether unknown to the Romans, than any of the paſſages already cited. He ſays (Dig. l. xlv. de verb. oblig.), "Illa ſtipulatio, decem millia ſalva fore promittis? valet." This paſſage, however, ſhews, as ſerjeant Marſhall has obſerved, that the contract alluded to, whatever it might have been, was very little known at the time when Ulpian wrote, ſince he thought it neceſſary to remark, that "it was not illegal." Malyne, Anderſon, &c. affirm, that inſurance is mentioned in the marine laws of the iſle of Oleron, on the coaſt of France, which was much celebrated in the 11th, 12th, and following centuries, on account of its trade. But in theſe laws there is no trace of inſurance, as the learned editor, Cleirac, acknowledges. The celebrated maritime laws of the city of Wiſby, in the iſland of Gothland, are equally ſilent with regard to inſurance. Inſurance was, undoubtedly, not known in 1597, when the ordinances of the Hanſeatic league were framed, nor in 1614, when ſeveral new regulations were added; becauſe, though the contract of bottomry is mentioned in theſe regulations, there is not a word on the ſubject of inſurance, nor does any thing certain occur in the collection of maritime laws, intitled "Il Conſolato del Mare," written in the Catalonian dialect, partly framed in the 11th, but for the moſt part in the 13th century, and publiſhed at Leyden in 1704. (See *Marine* LAW.) Some have ſaid, without ſufficient authority, that the practice of inſurance was introduced by the Jews in 1182; and others have ſought its origin about the year 1560, in the great woollen commerce that ſubſiſted between England and the Netherlands. But as the maritime commerce of the Italian ſtates appears to have been carried on to a very conſiderable extent about the end of the 13th century, it is very probable that inſurance came into uſe in Italy about that time. From thence it was tranſplanted into all the countries where the Lombards had eſtabliſhed their trading companies. One of theſe companies ſettled in London, and from them Lombard-ſtreet in that capital took its name. According to Malyne inſurance was introduced into England by the Lombards ſomewhat earlier than into the neighbouring countries on the continent; and in proof of this, he ſays, that even Antwerp, in its meridian glory, borrowed inſurance from England; and that, down to the time in which he wrote (1622), there was, in every policy made at Antwerp, and other places in the Low Countries, a clauſe inſerted, that it ſhould be in all things the ſame as policies made in Lombard-ſtreet, in the city of London; the place where the Lombards are known to have firſt ſettled, and carried on their commerce in England, and where the merchants of London uſed to hold their meetings before the Royal Exchange was built. Anderſon (Hiſt. of Commerce) ſays, that the vaſt commerce carried on about the middle of the 16th century, between England and the Netherlands, introduced the practice of inſuring from loſſes by ſea, by a joint contribution. But the preamble to the ſtatute 43 Eliz. c. 12, already cited, which ſtatute was paſſed in 1601, diſtinctly ſtates, that it had been an "immemorial uſage" among merchants, both Engliſh and foreign, when they made any great adventure, to procure inſurance to be made on their ſhips or goods adventured. From this it may be reaſonably ſuppoſed, that inſurance muſt have been in uſe in England long before the middle of the preceding century. The law of inſurance, ſays Mr. Marſhall (ubi infra), is conſidered as a branch of marine law; and it is alſo a branch of the law of merchants (ſee LAW); and it may be collected from theſe two ſources in the ordinances of different commercial ſtates, in the treatiſes of learned authors on the ſubject of inſurance, and in judicial deciſions of this country, and alſo of others profeſſing to follow the general marine law and the law of merchants. The earlieſt ordinance now extant on the ſubject of inſurances is that of Barcelona, ſuppoſed to have been publiſhed about the year 1435. The next ordinance on this ſubject was publiſhed at Florence in the beginning of the year 1523. The emperor Charles V. in 1551 publiſhed ſeveral regulations concerning maritime commerce, called the "Caroline" code, to which his ſon Philip II. added a number of new ordinances in 1563 and 1565. Magens, in his "Treatiſe on Inſurance, Average, and Bottomry," publiſhed at Hamburgh in 1753, has collected many of theſe ordinances; but the moſt complete ſyſtem of poſitive law for the regulation of inſurances, that has yet appeared in any country, may be found in the celebrated ordinance of the marine of Louis XIV., publiſhed in 1681. The ſtatutes pertaining to this ſubject, which have been enacted in England, have not been numerous; and, therefore, the practice among us has been found moſt conformable to the general uſage of trade. As to treatiſes on inſurance, the earlieſt now extant is that entitled "Le Guidon de la Mer," which is found in the collection of marine inſtitutions, publiſhed at Rouen in 1671 by Cleirac, under the title of "Les Us et Coûtumes de la Mer." This is ſuppoſed to have been written about the 15th century. In France, Valin, Pothier, and Emerigon, have written on this ſubject. The treatiſe of the latter is, in the judgment of ſerjeant Marſhall, the moſt uſeful to an Engliſh lawyer of all the foreign publications on this ſubject. Roccus, Caſaregis, Locennius, Bynkerſhoek, and Santerna, have alſo publiſhed treatiſes on this ſubject. We have alſo in England detached obſervations on inſurance in the treatiſes of Malyne, Molloy, Beawes, Poſtlethwaite, and ſome others of leſs note. Mr. Magens, a merchant, in 1735, republiſhed in two volumes 4to. his "Eſſay on Inſurance," which he had before publiſhed in German at Hamburgh. Mr. Millar, a learned advocate at the Scots bar, publiſhed at Edinburgh, in 1787, the "Elements of the Law relating to Inſurances;" Mr. Park has alſo given to the world his excellent "Syſtem of the Law of Inſurances;" and in 1802 the public was favoured by Samuel Marſhall, ſerjeant at law, with his "Treatiſe on the Law of Aſſurance," in 4 books, containing an ample account of every thing that is eſſentially neceſſary to be known on this ſubject. As to judicial deciſions, none of theſe are conſidered as binding authorities in our ſuperior courts, except ſuch as have been there determined; and even theſe may be re-conſidered and over-ruled. Before the paſſing of the act of queen Elizabeth, above cited, almoſt all diſputes, ariſing upon contracts of inſurance, were ſettled by arbitration, and without recurring to any legal proceedings. And there ſeems to have been a particular tribunal for ſuch arbitrations, eſtabliſhed in London, compoſed of perſons annually appointed by the lord mayor. From Malyne we learn that there was an "office of aſſurances," on the weſt ſide of the Royal Exchange, where inſurances were made; and to this office belonged certain commiſſioners, who were annually appointed. The authority of theſe commiſſioners was confirmed by act of parliament, in the latter period of the reign of queen Elizabeth. (See COURT *of Policies of Aſſurance.*) This court gradually ſunk into diſrepute, and all ſuits on policies of inſurance were preferred in the courts of common law. After ſome of the deciſions of the courts of Weſtminſter, on queſtions of inſurance, came to be generally known, the confidence which the juſtice, impartiality, and ability of thoſe courts inſpired through Europe, ſoon induced the merchants of all countries to prefer Engliſh inſurances to thoſe of any other country.

The parties to the contract of inſurance are the inſured and the inſurers. In this country, all perſons, whether Britiſh ſubjects or aliens, may, in general, be inſured. The principal, if not the only exception to this rule, is the caſe of an alien enemy. The inſurance of the ſhips and merchandize of France, during a war with that country, is prohibited by 21 Geo. II. c. 4; and by 33 Geo. III. c. 27. § 4, which latter ſtatute not only declares ſuch inſurances to be void, but alſo ſubjects the parties concerned in them to three months' impriſonment. The policy of this prohibition was however diſputed in 1741, by ſir John Barnard, and in 1748 by ſir Dudley Rider and Mr. Murray, then attorney and ſolicitor-general. But their objections were over-ruled. Nevertheleſs, it appears that a neutral, though reſiding in the enemy's country, and carrying on trade there, and even in partnerſhip with an alien enemy, may inſure his intereſt in the joint property.

Thoſe who are inſurers, or underwriters, ſhould be perſons of great prudence and circumſpection; and caſes may occur, which will require more than ordinary ſagacity, penetration, and experience. At common law, any man, or company of men, might be inſurers; and individuals, upon their own ſeparate account, have ſtill the ſame right. But about the beginning of the laſt century it was thought expedient, partly with a view of counteracting the evil ariſing from inſurance by inſufficient perſons, and perhaps, principally for enabling government to raiſe a ſum of money by the ſale of a monopoly, to erect two companies for making marine inſurances, with ſuch funds to anſwer all demands on their policies as might give confidence to mercantile adventurers, who were unwilling to depend on individual underwriters; ſtill, however, leaving to merchants the option of inſuring with ſuch underwriters whom they thought proper. To this end the ſtat. 6 Geo. I. c. 18, authorized the king to grant charters to two diſtinct companies or corporations, for the inſurance of ſhips, goods, and merchandize, at ſea, or going to ſea, and for lending money on bottomry. In purſuance of the powers given by this act, the two propoſed companies, the one called the "Royal Exchange Aſſurance," and the other the "London Aſſurance," were eſtabliſhed by royal charter, bearing date June 22, 1720. The moſt important privilege granted to theſe companies was the excluſive right of making marine inſurances, and lending money on bottomry, as a "Company" or "Partnerſhip," on a "joint capital."

Inſurance is ſaid to be "a contract of indemnity from loſs or damage, ariſing upon an uncertain event." So that the object of inſurance is to avoid a poſſible loſs. Hence it appears, that there cannot be an indemnity without a loſs, nor a loſs without an intereſt. A policy, therefore, without intereſt, is not an inſurance, but a mere wager. It is not eaſy to define and aſcertain inſurable intereſt. The intereſts of commerce, and the various rights which different perſons may have in the ſame thing, require that not only thoſe who have an "abſolute" property in ſhips and goods, but thoſe, alſo, who have a "qualified" property in them, may be at liberty to inſure them; and this principle has been ſo extended, that if a merchant abroad, in order to ſecure the payment of a debt due to his correſpondent in England, mortgage to him his intereſt in certain goods and freight; the correſpondent, after the mortgage becomes abſolute, may inſure the "legal" intereſt on his own account, or the "equitable" intereſt on account of the mortgagor. A reaſonable expectation of "profit," or a well-founded expectation of a future intereſt in the thing inſured, is an inſurable intereſt. But a mere hope or expectation of future gain, however well founded, is not an inſurable intereſt, unleſs accompanied by poſſeſſion of the ſubject-matter of the inſurance. Of this nature is the intereſt which the captor acquires in a prize regularly taken in war. It alſo appears, that perſons in the character of "truſtees," for the diſpoſal of ſhips and goods according to ſuch inſtructions as they might receive from third perſons, may inſure ſuch ſhips and goods for the benefit of the perſons who may eventually be entitled to the produce of them. Accordingly, commiſſioners, entitled "The Honourable Commiſſioners for the Sale of Dutch Property," were appointed by 35 Geo. III. c. 80. § 21. to take into their care all Dutch ſhips, &c. detained in Britiſh ports, and to diſpoſe of them in purſuance of directions from the privy council; and they were authorized to inſure, in their own names, ſuch ſhips, after ſeizure at ſea, and while they were on their paſſage to England. At common law, an inſurance might have been made without intereſt; nor is it neceſſary to aver intereſt in any caſe not prohibited by 19 Geo. II. c. 37. An inſurable intereſt can only be founded on a legal or equitable title; but a mere claim, which the law cannot admit to be either legal or equitable, is not an inſurable intereſt. As freight can only be due to the legal owner of a ſhip, he only can inſure it; and no perſon can have either a legal or equitable title to a ſhip, unleſs he be named in the regiſter. Although "reſpondentia" and "bottomry" are of themſelves a ſpecies of inſurance, yet the lender has an inſurable intereſt in his ſecurities, and therefore may protect himſelf from the ſea-riſk by inſuring them. However, a policy on bottomry or reſpondentia cannot be ſubſcribed by the borrower of the money; for if he were to become an inſurer, this would be no longer a loan upon bottomry, but a cloak for uſury. See *Wager* POLICY, and the ſequel of this article.

Inſurances are of various kinds, as on ſhips or parts of ſhips, on merchandize ſingly, and on ſhips and goods jointly, on freight, and bottomry loans; and theſe are again branched out to run either for a time ſtipulated, or to one ſingle port, or out and home, with liberty to touch at the different places mentioned in the policy.

It is laid down as a general rule, that no inſurance can be legally made upon any voyage undertaken contrary to the laws of this kingdom, or to thoſe of its dependencies, or to the law of nations. Nor is it of any importance whether the inſurer was or was not informed that the voyage was illegal. Conſequently, an inſurance upon a voyage undertaken contrary to the navigation laws would be void. The caſe is the ſame with regard to a voyage prohibited by the laws made for the protection of the monopoly of the Eaſt India company. Under the treaty allowing the Americans to trade to the Britiſh colonies in India, concluded in 1795 and confirmed by 37 Geo. III. c. 97, it is not neceſſary that this trade ſhould be carried on from America to the Britiſh ſettlements in the Eaſt Indies "direct;" but it may be carried on "circuitouſly" by the way of Europe. With reſpect to the riſks or perils againſt which inſurances are uſually made, they are expreſſed in the words of the policy, which are as follow: "Touching the adventures and perils which we the aſſurers are contented to bear, and do take upon us in this voyage, they are of the ſeas, men of war, fire, enemies, pirates, rovers, thieves, jettiſons, letters of mart and countermart, ſurpriſals, takings at ſea, arreſts, reſtraints and detainments of all kings, princes, and people, of what nation, condition, or quality whatſoever: barratry of the maſter and mariners; and of all other perils, loſſes, and misfortunes, that have or ſhall come to the hurt, detriment, or damage of the ſaid goods and merchandize, and ſhip, &c., or any part thereof, without prejudice to this inſurance." But by the agreement of the parties, the general words of the policy may be altered or qualified, and any of the riſks may be wholly or in part excluded: and the inſurance may be made only againſt ſome particular riſks, or up to, or beyond certain degrees, or upon particular articles. In the policies of moſt countries it is ſtipulated that the inſurer ſhall not be liable for any partial loſs under a given rate *per cent*. A clauſe to this purpoſe, which was firſt introduced in 1749, is inſerted at the bottom of all Engliſh policies. Nevertheleſs, the inſurer is liable for loſſes, however ſmall, called "general average," and loſſes occaſioned by the "ſtranding of the ſhip." In the policies of private underwriters the memorandum is as follows: "corn, (comprehending every ſort of grain, and alſo peaſe and beans,) fiſh, ſalt (not including ſalt-petre), fruit, flour and ſeed, are warranted free from average, unleſs general (denoting loſſes ariſing from any cauſe affecting the general ſafety of the ſhip and cargo), or the ſhip be ſtranded: ſugar, tobacco, hemp, flax, hides and ſkins are warranted free from average, under 5 *per cent.*, and all other goods, alſo the ſhip and freight, are warranted free from average, under 3 *per cent.* unleſs general, or the ſhip be ſtranded." In 1754 the two companies, *viz.* thoſe of the *London* and *Royal Exchange* aſſurance left out the words, "or the ſhip be ſtranded;" but private underwriters have continued them. If any loſs or damage happen to the goods, from any fault or defect of the ſhip, the owner has his remedy againſt the proprietors of the ſhip, and the inſurer is not liable; becauſe, in every contract of inſurance, there is an implied warranty, that the ſhip is ſea-worthy: if otherwiſe, the contract is void. In many caſes the maſter alſo is liable. The marine law, with which agrees the common law of England, conſiders the owners, as well as the maſter, as common carriers, and anſwerable for all loſſes, except ſuch as ariſe from the act of God, the king's enemies, or the perils of the ſea. In order to charge the inſurer, the loſs muſt happen in the courſe of the voyage, and during the continuance of the riſk. In our policies the words uſually employed to expreſs the commencement and end of the riſks on goods are theſe: "Beginning the adventure upon the ſaid goods and merchandize *from the loading thereof aboard the ſaid ſhip*, and ſo ſhall continue and endure until the ſaid ſhip with the ſaid goods ſhall be arrived at ——— (her port of delivery), and until the ſame be diſcharged and ſafely landed." This rule, however, admits of ſome exceptions, which our limits will not allow us to enumerate. The duration of the riſk on the ſhip varies with us in almoſt every caſe. In outward-bound voyages it is generally made to commence from her beginning to load at her port of departure. Ships engaged in the coaſting-trade, or in ſhort voyages, are inſured for a limited period of time; and in ſuch caſes, the riſk commences and ends with the term, wherever the ſhip may then happen to be. If a ſhip be inſured *from* the port of London to any other port, and before ſhe breaks ground, an accident happen to her, the inſurers are not anſwerable; for the riſk does not commence till ſhe ſets ſail on her departure from the port of London: but if the inſurance be "*at and from*" the port of London, the inſurers are liable for any accident that may happen to her, "*from the time of ſubſcribing the policy.*" When a ſhip, in homeward voyages, expected to arrive at a certain place abroad, is inſured "*at and from*" that place, or from her arrival there, the riſk begins from the firſt moment of *her arrival at the place* ſpecified; and the words "*firſt arrival*" are implied, and always underſtood in policies ſo worded. As to the termination of the riſk on Engliſh policies, it is uſually made to continue only "*until the ſhip hath moored at anchor 24 hours in good ſafety.*" The riſk on the furniture, the rigging and tackle, and proviſions of the ſhip, may continue even when put on ſhore. With inſurers, a liberty to touch and ſtay at any ports and places, means ports and places in the uſual courſe of the voyage. This liberty to touch and ſtay at any ports or places, does not authorize the inſured to break bulk and trade. Although a ſhip, through neceſſity, change the order of the places at which ſhe is to touch, yet if ſhe do not abandon the original voyage, the riſk continues. In an inſurance upon freight, the riſk generally begins from the time the goods are put on board. If an accident happen to the ſhip before any goods are put on board, which prevents her from ſailing, the inſured cannot recover for the loſs of freight, which the ſhip might have earned if the accident had not happened. But if part of the cargo be put on board, and the reſt be ready to be ſhipped, the inſured may recover for the whole freight, upon a valued policy. (See POLICY.) If a ſhip be loſt in her way to her port of loading, the inſurer is liable for the whole freight.

If, after the inſurance is effected, any thing be done by the inſured to alter the nature of the riſk, this muſt be done with the conſent of the inſurer, otherwiſe it will avoid the contract.

Inſurances may likewiſe be made on goods ſent by land, or by hoys, &c. on rivers; and this is frequently done, more eſpecially on jewels, and other things of great value. They may likewiſe be made on ſhips and goods, loſt or not loſt, which is commonly done when a ſhip has been long miſſing; and thoſe words being inſerted in the policy, oblige the underwriters to pay, though the ſhip was loſt at the time of making ſuch inſurance, except the aſſured had then certain knowledge of the ſhip's being wrecked; in which caſe the ſubſcription ſhall not oblige, as this is accounted a mere fraud. So likewiſe if a perſon get more inſured than the ſhip is worth, with a villainous deſign to deſtroy her, this fraudulent act will not oblige the inſurers, but expoſe the proprietors to ſuffer death for their knavery. An inſurance made on prohibited goods is illegal and void, unleſs they were not prohibited till after the inſurance was made. The inſurance of ſeamen's wages is prohibited in all maritime countries; and by the law of England ſuch inſurance is unqueſtionably illegal. But they may inſure goods purchaſed abroad with their wages; and the captain is allowed to inſure goods which he has on board, or his ſhare in the ſhip, if he be a part-owner. By the law of France, the inſurance of freight, not actually earned, is prohibited; but in England the freight, as well as the ſhip, may be legally inſured. To entitle the owner, however, to recover for a loſs on a policy for freight, it muſt appear, that, before the loſs, the owner's right to freight had commenced; that is, that the ſhip had actually begun to earn freight, for till that time the riſk on freight does not commence. Although it is not unuſual in England to inſure profit, the queſtion whether this be a proper ſubject of inſurance has never yet come under ſolemn diſcuſſion. Where the policy expreſsly mentions that the ſhip is to depart with convoy, it is intended that ſhe ſhall, if poſſible, keep with the convoy during the voyage, and if ſhe depart wilfully from the convoy, it is a fraud; but if having departed with the convoy, ſhe by ſtreſs of weather loſes the convoy, and is taken, the inſurers are liable. (See WARRANTY.) If there be thieves on board among themſelves, the maſter of the ſhip is to anſwer for that, and not the inſurers; for though the words of the policy inſure againſt loſſes by thieves, yet aſſailing or external thieves are only here intended, and for external theft the inſurer as well as the owner of the ſhip is liable; but the proprietor of the goods, or the inſurers in his name, may recover againſt the owners. An inſurance made in a foreign country, may be ſued in England by the common law, if the inſurers come here. Where the policy is againſt reſtraint of princes, that does not extend to a navigation carried on againſt the law of nations, or where there ſhall be a ſeizure for not paying of cuſtoms or the like. If goods be inſured as the goods of an ally, when they are the goods of an enemy, it is a fraud, and the inſurance not good. If a man pays money on a policy of inſurance, ſuppoſing a loſs where there was none, this ſhall be money received for the uſe of the inſurer, for which he may maintain an action. A ſuppreſſion of the truth, or a falſe allegation, is ſufficient to diſcharge the policy; for it is a general rule, that the inſured ought to inform the inſurer of all material circumſtances that were come to his knowledge at the time of making the policy, in order that the contract may be fairly adjuſted; which being a contract upon chance, cannot be done, if one party knows more than the other; for equality in contracts, by the law-merchant, is eſſential; but a proof of an intention to make a deviation, will not avoid the policy before the deviation is actually made. See Representation.

By an act made in 19 Geo. II. c. 37. it is determined, that after the firſt day of Auguſt, 1746, no inſurance ſhall be made on ſhips or lading, "intereſt or no intereſt," or "without further proof of intereſt than the policy," or by way of gaming or wagering, or without benefit of ſalvage to the inſurer, and that every ſuch inſurance ſhall be void: that it ſhall not be lawful to make re-inſurance, unleſs the inſurer ſhall become inſolvent, become a bankrupt, or die: in which caſes ſuch inſurer, or his executors, &c. may make re-inſurance to the amount of the ſum before inſured, provided it be expreſſed in the policy to be a re-inſurance (ſee Reinsurance): that all ſums of money lent on bottomry or reſpondentia, upon any ſhips belonging to his majeſty's ſubjects, bound to or from the Eaſt Indies, ſhall be lent only on the ſhip or merchandize, laden, or to be laden, on board ſuch ſhip, and ſhall be ſo expreſſed in the condition of the bond; and the benefit of ſalvage ſhall be allowed to the lender, his agent or aſſigns, who alone ſhall have a right to make inſurance on the money ſo lent; and no borrower of money on bottomry, &c. ſhall recover more on any inſurance, than the value of his intereſt in the ſhip or merchandize, excluſively of the money ſo borrowed; and in caſe it ſhall appear, that the value of his ſhare in the ſhip and merchandize does not amount to the full ſum borrowed, ſuch borrower ſhall be reſponſible to the lender for ſo much of the money borrowed, as he hath not laid out on the ſhip or merchandize, with lawful intereſt for the ſame, together with the inſurance and all other charges, to the proportion which the money not laid out ſhall bear to the whole money lent, notwithſtanding the ſhip and merchandize be totally loſt. And, in all actions brought by the inſured, the plaintiff, or his attorney or agent, ſhall, within 15 days after he ſhall be required ſo to do, in writing, by the defendant, or his attorney or agent, declare in writing what ſum or ſums he hath inſured or cauſed to be inſured in the whole, and what ſums he hath borrowed, at reſpondentia or bottomry, for the voyage, or any part of the voyage in queſtion.

Whenever advice is received of the loſs of a ſhip or goods inſured, application is to be made to the inſurers, and the vouchers produced; and if they are ſatisfied, they will pay the money: but if they have cauſe to ſcruple the doing it, the inſured muſt ſtay till the inſurer can obtain a more ſatisfactory account; but if nothing be heard of the ſhip in any reaſonable time, the inſurers will be obliged to pay the money agreed upon.

In adjuſting a loſs, the quantity of damage for which the underwriters are reſponſible is firſt to be aſcertained; and the next point to be ſettled is by what rule this ſhall be appretiated. The adjuſtment is uſually indorſed on the policy and ſigned by the underwriters. When the loſs is admitted to be *total*, and the policy is a valued one, the inſured is entitled to receive the whole ſum inſured, ſubject to ſuch deductions as may have been agreed by the policy to be made in caſe of loſs. It is merely in reſpect of total loſs that any difference ſubſiſts between an open and a valued policy. Upon the latter the value is admitted, and the inſured has only to prove, if the inſurance was on goods, that the goods valued were on board. Upon an open policy, it is neceſſary to prove, not only that the goods were on board, but alſo the value of them, which the inſurers, provided it does not exceed the ſum inſured, are bound to pay. But in the caſe of a *partial* loſs, the amount of the loſs ſhould be aſcertained in both kinds of policy. When a part of the goods inſured is ſaved, and this exceeds the amount of the freight, the practice is to deduct the freight from the ſalvage, and to eſtimate the loſs by the difference; but when the freight exceeds the ſalvage, then it is a total loſs. If the goods inſured are damaged in the whole, or in part, it will be neceſſary to aſcertain the *quantity* of ſuch damage, which is done by taking the value of the goods, in their damaged ſtate, from the prime coſt; and the remainder will be the amount of the loſs. If ſeveral articles be inſured for one entire ſum, but with a diſtinct valuation to each, and only one be ſent in riſk, and if that one be loſt, the inſured ſhall recover ſuch a proportion of the ſum inſured as the value of that article bore to the value of the whole. If the policy has a clauſe, to be free of average from a particular riſk, under ſo much *per cent.* and a loſs occaſioned by that riſk takes place, the proportion which the loſs bears to the cargo muſt be calculated upon the cargo which was on board when the loſs happened, not upon that which was on board at any other time. With reſpect to the valuation of goods inſured, there has been a difference of opinion; ſome contending for the prime coſt, others for the current price at the time of loſs; ſome again inſiſting on the price at the time and place of ſhipping the goods, others on the price at the port of diſcharge. In England, if the policy be an open one, it is an invariable rule to eſtimate a total loſs, not by any ſuppoſed price which the goods might have been deemed worth at the time of the loſs, or for which they might have been ſold, if they had reached the market for which they were deſtined; but according to the prime coſt, that is, the invoice price, and all duties and expences till they are put on board, together with the premium of inſurance. The value is never affected by the riſe or fall of the market, nor by the courſe of exchange. A ſhip is valued at the ſum ſhe is worth at the time when ſhe ſails on the voyage inſured, including the expence of repairs, the value of her furniture, proviſions and ſtores, the money advanced to the ſailors, and, in general, every expence of the out-fit, to which is added the premium of inſurance. A partial loſs upon either ſhip or goods is that proportion of the prime coſt, which is equal to the diminution in value occaſioned by the damage. An adjuſtment, being indorſed on the policy and ſigned by the underwriters, with a promiſe to pay in a given time, is *primâ facie* evidence againſt them, and amounts to an admiſſion of all the facts neceſſary to be proved by the inſured to entitle him to recover in an action on the policy. It is like a note of hand, and being proved, the inſured has no occaſion for further proof. An adjuſtment, however, may be impeached by ſhewing that the underwriter was induced to ſign it by ſome fraud or concealment, or by ſome miſconception of the law or fact; but this muſt be done by evidence, and not by doubts or ſurmiſes after the time for payment is come.

If it be inquired, under what circumſtances the inſured ſhall be entitled to demand a return of premium, the particular caſes are as follow. In general, the premium ought to be returned, when the contract is void *ab initio;* that is, either for want of intereſt in the inſured, or becauſe the inſurance is illegal, or on account of fraud on the one ſide or the other. However, upon a wager-policy the inſured cannot recover back the premium, at leaſt after the riſk is run. 19 Geo. II. c. 37. But before the riſk is run, and while the contract is executory, the inſured may recover back the premium. If the contract be void, as being a re-inſurance, within the above cited ſtatute, the inſured ſhall not be intitled to a return of premium. If, under any circumſtances, the inſurer might, at any time, have been called upon to pay the whole ſum inſured, the premium is earned, and he ſhall not be obliged to return any part of it. Although an inſurance to protect trading with the enemy is void, yet the inſured ſhall not recover back the premium. In the caſe of fraud likewiſe on the part of the inſurers, the premium ſhall be returned. However it has been doubted, whether the inſurer be bound to return the premium, in a caſe where fraud has been committed by the inſured. The court of chancery, in two inſtances, ordered a return of premium where the policies were declared void for fraud committed by the inſured. The courts now hold a contrary doctrine. As to the commencement of the riſk, the rule in England is, that where the riſk has not been begun, whether this be owing to the fault, pleaſure, or will of the inſured, or to any other cauſe, the premium ſhall be returned. But if the inſurances be upon a voyage, diviſible into ſeveral diſtinct riſks, or, which amounts to the ſame, into ſeveral diſtinct voyages, the premium may be apportioned, according to theſe ſeveral riſks; and if one or more of theſe riſks ſhould not have been commenced, the proportion of premium applicable to thoſe parts ſhall be returned. But if the riſk be entire and be once commenced, there ſhall be no return. If part of the premium is to be returned upon the performance of ſome ſtipulation agreed upon between the parties, this ſhall be returned, though the inſurer be obliged to pay a partial loſs. As the inſurer can never, by his own act, diſcharge himſelf from the contract, it ſeems reaſonable, that, where the inſured thinks proper to put a ſtop to the adventure, and prevent the riſk from ever commencing, he ſhould make ſome compenſation to the inſurer for his trouble and diſappointment; it is therefore the general cuſtom in all the maritime countries of Europe, to allow him to retain one-half *per cent.*

With regard to actions on policies of inſurance, the ſole juriſdiction belongs to the courts of common law; and the proper form of action againſt private underwriters, is ſpecial "Aſſumpſit;" which ſee. The two inſurance companies, being corporations, can do no act but by deed under their common ſeals. Their policies of inſurance, being under ſeal, no action of "Aſſumpſit" will lie upon them, but only debt of covenant. See ſtat. 6 Geo. I. c. 18, and 8 Geo. I. c. 30. The evidence generally adduced on the part of the plaintiff is reducible to the following heads, *viz.* proof of the contract, payment of the premium, intereſt of the inſured, performance of warranties and loſs. For a further detail of theſe and other particulars, relating to matters of inſurance, and the determinations of judges and courts of law in illuſtration and confirmation of them, ſee "A Treatiſe on the Law of Inſurance," by Samuel Marſhall, ſerjeant at Law, in 2 vols. Lond. 1802. On this ſubject, ſee farther under BARRATRY, *Inſurance* BROKERS, DEVIATION, POLICY, SALVAGE, UNDERWRITERS, and WARRANTY. See alſo BOTTOMRY and RESPONDENTIA.

INSURANCE *upon Lives*, is a contract by which the inſurer, in conſideration of a certain premium, either in a groſs ſum or by annual payments, undertakes to pay the perſon, for whoſe benefit the inſurance is made, a ſtipulated ſum of money, or an equivalent annuity, upon the death of the perſon whoſe life is inſured, whenever this ſhall happen, if the inſurance be for the whole life, or in caſe this ſhall happen within a certain period, if the inſurance be for a limited time. For the principles on which this kind of inſurance is made, and other particulars relating to it, ſee the article ASSURANCE. It is generally a condition or warranty, in inſurances upon lives, either inſerted in the policy, or contained in a declaration or agreement ſigned by the inſured, that the perſon whoſe life is meant to be inſured has not any diſorder which tends to the ſhortening of life; that he has, or has not, had the ſmall-pox; and that his age does not exceed ſo many years; that this declaration ſhall be the baſis of the contract between the inſurers and the inſured; and that if any untrue averment be contained therein, the contract ſhall be void, and all money paid on account of the inſurance forfeited. As this declaration is to be taken as part of the written contract, amounting to a warranty, it behoves every perſon who makes an inſurance upon a life, to be very circumſpect in aſcertaining the truth of the allegations which it contains; becauſe upon that the validity of the contract muſt depend. When there is no warranty, the inſurer takes the riſk upon himſelf, whatever may be the ſtate of health of the perſon whoſe life is inſured, unleſs there be ſome fraudulent miſrepreſentation or concealment.

In order to check the ſpirit of gaming, which is ready to avail itſelf of inſurance upon lives, it is enacted by ſtat. 14 Geo. III. c. 48. § 1, that no inſurance ſhall be made by any perſon or perſons, bodies politic or corporate, on the life or lives of any perſon or perſons, or on any other event or events whatever, wherein the perſon or perſons, for whoſe uſe or benefit, or on whoſe account, ſuch policy or policies ſhall be made, ſhall have no intereſt, or by way of gaming or wagering; and that every inſurance made contrary to the true intent and meaning of this act, ſhall be null and void to all intents and purpoſes whatſoever; and that it ſhall not be lawful to make any policy or policies on the life or lives of any perſon or perſons, or other event or events; without inſerting in ſuch policy or policies the name or names of the perſon or perſons intereſted therein, or for what uſe or benefit, or on whoſe account, ſuch policy is ſo made or underwrote;—and that in all caſes where the inſured hath an intereſt in ſuch life or lives, event or events, no greater ſum ſhall be recovered, or received from the inſurer or inſurers, than the amount or value of the intereſt of the inſured in ſuch life or lives, or other event or events. This act extends to every ſpecies of inſurance except marine inſurances, which are expreſly excepted. The different inſurance companies annex to the contract certain conditions or exceptions. For thoſe of the "Royal Exchange Aſſurance" (ſee ASSURANCE.) The ſame exceptions are adopted by the "Weſtminſter Society." The "Equitable Aſſurance," and the "Pelican Life-inſurance," adopt the ſame exceptions, only omitting the word "duelling," even where the party inſures his own life. Other ſocieties for inſurance on lives, ſuch as the "Rock Inſurance Society," &c. have been more recently eſtabliſhed, and inſurances of this kind are made by ſome of thoſe ſocieties, which will be noticed in the next article.

The ſocieties which reſtrict themſelves to inſurance on lives are the following; *viz.* the "Amicable Society," incorporated by royal charter of queen Anne in 1706, ſanctioned by the grant of two ſubſequent charters in 1730 and in 1790, and further improved under the powers conferred by a new charter in 1807. By virtue of this charter, perſons are admitted to inſure their own lives, or the lives of others, in which they may have an intereſt, on the following payments:

Table for the whole of life, for each ſhare, amounting to 180*l. with ſuch addition as the circumſtances of the year may produce*, to be paid on the death of the inſured.

Age.	Premium on Admiſſion.	Annual Contribution.	Age.	Premium on Admiſſion.	Annual Contribution.

The whole of the annual contributions for every ſhare granted previous to the laſt charter, and ſeven eighths of the contributions on ſhares ſubſequently granted, are to be divided every year amongſt the claimants by deaths which happen in that year: a principle of diviſion, which is calculated, in the general courſe of things, to raiſe each claim conſiderably above 180*l.* which ſum at leaſt the corporation engages each ſhare ſhall produce to the claimant. See ASSURANCE.

The "Society for Equitable Aſſurances on Lives and Survivorſhips" was eſtabliſhed by deed, inrolled in his majeſty's court of king's bench, Weſtminſter. For an account of this ſociety, which has acquired high reputation, under the conduct of its preſent actuary, William Morgan, eſq. ſee ASSURANCE. The "Weſtminſter Life Inſurance Office" was eſtabliſhed in 1792. The "Pelican Office" for inſurance of lives, granting annuities and endowment of children, was eſtabliſhed in the year 1797. The "Rock Life Aſſurance Company" was inſtituted in 1806, on a principle different from that of any ſociety hitherto eſtabliſhed for the aſſurance of a ſum to the repreſentatives of a perſon aſſured. The company conſiſts of a number of proprietors, poſſeſſing a capital ſtock of one million; and each proprietor is under the neceſſity of aſſuring a ſum on his own life, if accepted by the directors; or on that of an approved nominee, to the amount of one quarter of the ſtock in his name. Thus by aſſuring each other's lives, the proprietors have a mutual intereſt in the ſupport of the ſociety, and are engaged to each other to take care that no improper life, with their knowledge, be admitted into it. By the mode of aſſuring property in this ſociety, the repreſentatives of the aſſured receive a certain ſum at his deceaſe, and whatever addition may have been aſſigned to that ſum by the previous reſolution of the ſociety, agreeably to its deed of ſettlement. The perſons who aſſure in this office are not all partners; they are not all reſponſible for the payment of the ſum aſſured to each individual. The aſſured are either proprietors or non-proprietors. The proprietors are anſwerable each to a certain amount; they lay down a certain ſum, and form a determinate capital to anſwer all contingencies, and by thus forming a capital, they are enabled to make a due aſſignment of the ſum to be added at different periods to various policies of aſſurance. The aſſured non-proprietors have no ſhare in the riſk: they pay down definite premiums, which aſſure to the repreſentatives the ſum aſſured, and who partake equally with proprietors in the addition which may be made at different periods to each policy. The ſecurity for the payment of that ſum is the capital ſtock of the company and the amount of all the premiums, with the intereſt upon them. Such a ſecurity, it is ſaid, may be deemed as a "rock," whence we apprehend the company derives its appellation; for the transfer of ſhares will produce a continual renovation of policies, which, with the capital of the company, and the amount of annual payments from aſſurances, will form an increaſing fund, adequate to every purpoſe of profit and ſecurity. The character of William Frend, eſq. the actuary of this ſociety, as a mathematician, is well known. The "Provident Life Inſtitution" was eſtabliſhed in 1806. In the ſame year was alſo eſtabliſhed the "Philanthropic Annuity Inſtitution;" the object of which is to enable thoſe, who wiſh to raiſe an immediate ſum of money by the grant of annuities, or to inveſt money for the purpoſe of accumulation, to do it on the moſt advantageous terms ſuited to the various circumſtances and contingencies of life; and alſo to provide endowments for children, &c. The inveſtment of money in this inſtitution may be made in three different ways: 1ſt, by paying a certain ſum of money down, to receive an annuity, to commence immediately: 2dly, by paying down a certain ſum of money, to receive an annuity, to commence at a future time: and, 3dly, by paying a ſum of money at particular periods, to receive back a ſum, or an annuity when the inveſtor requires it. The "London Life Aſſociation" for the aſſurance of lives, conſiſts of perſons inſuring their reſpective lives for the whole term of life; and the members become, to the amount of their policies, mutual aſſurers to one other. The ſociety alſo undertakes every deſcription of aſſurance on the lives of perſons, not members; and it is part of its plan to make endowments, and to grant and purchaſe annuities, by virtue of an act of parliament of the 47th Geo. III. c. 32. The diſtinguiſhing principle of this ſociety is, that the benefits reſulting from its tranſactions ſhall be enjoyed by the members, during life, ſo as to render life aſſurance as eaſy to the aſſured, as a due regard to ſecurity will admit. The "Royal Exchange Aſſurance Annuity Company" has been already mentioned under the article ASSURANCE: but in May 1803, the following table of rates was formed:

A Table of Rates of the Royal-Exchange Aſſurance Annuity Company.

N. B. The foregoing annuities are receivable in quarterly Payments.

Insurances *againſt Fire*, are founded on a contract, by which the inſurer, in conſideration of a certain premium, received by him, either in a groſs ſum, or by annual payments, undertakes to indemnify the inſured againſt all loſs or damage which he may ſuſtain in his houſes or other buildings, goods, and merchandize, by fire, during a limited period of time. Although the preciſe time of the introduction of this kind of inſurance into England cannot be aſcertained, it has certainly been in uſe here conſiderably more than a century. Of late years, notwithſtanding a very heavy, and we may add impolitic, ſtamp-duty impoſed on theſe inſurances, they have very generally, not to ſay univerſally, prevailed in this country: particularly in London, and other cities and large towns. In other countries they have been leſs general, and more recently introduced. The fire-office at Paris is ſaid to have been eſtabliſhed in 1745. In Holland, though inſurance againſt fire is not altogether unknown, yet few people ſeek its protection; becauſe they rely on their own caution, and do not chuſe to incur the expence of any greater ſecurity. It has, indeed, been confidently aſſerted, by perſons well acquainted with the cities both of London and Amſterdam, that after making all fair allowances, there is, upon an average, more property deſtroyed by fire in the former in one year than in the latter in ſeven years. Some perſons have charged many of the fires that occur in London and its vicinity on inſurance; but though negligence and fraud may in ſome inſtances derive encouragement from this eſtabliſhment, the benefits muſt be allowed far to overbalance the miſchiefs of which it is, directly or indirectly, productive. In London and other parts of the kingdom, companies or ſocieties for inſurances againſt fire have been very numerous; and their number has poſſibly been augmented by the emoluments that accrue to thoſe who eſtabliſh and conduct them. Some of theſe are called "Contribution Societies," in which every perſon inſured becomes a member or proprietor, participating in profit and loſs. Such are the "Hand in Hand," and the "Weſtminſter" fire-offices, for the inſurance of houſes and other buildings; and the "Union" fire-office, for inſurance of goods. The other companies inſure both houſes and goods at their own riſk. Of theſe the principal are the "London" and "Royal-Exchange" Aſſurance Corporations, the "Sun," the "Phœnix," and the "Britiſh" fire-offices.

As to the duties to which this contract is liable, the ſtat. 37 Geo. III. c. 90. § 23. repeals all the former ſtamp-duties impoſed on policies of inſurance againſt fire; and (by § 24.) impoſes on every policy, in lieu thereof, a new duty of *three ſhillings*, where the ſum inſured is under 1000*l.*, and of *ſix ſhillings* where the ſum inſured amounts to 1000*l.* or upwards. And by the ſtat. 44 Geo. III. a duty of *two ſhillings and ſixpence per cent. per annum* is to be levied on property inſured againſt fire. It is much to be regretted, that inſurances againſt fire are often made to a large amount upon property of very ſmall value; this can only be done with a fraudulent view, and a premeditated fire muſt be the neceſſary conſequences. Such practices require caution in the inſurers, ought to be reſtrained, and when they occur ſeverely puniſhed. If there be ſeveral inſurances on the ſame property in different offices, each office ſhould have notice, that the ſame may be allowed by indorſement on the policy; in order that each office may bear its rateable proportion of any loſs that may happen. But unleſs ſuch notice be given to the office where another inſurance is made on the ſame effects, the inſurance made without ſuch notice will be void. In general, the riſk commences from the ſigning of the policy, unleſs ſome other time be ſpecified; and it will of courſe end with the term for which it is made. Inſurances againſt fire are, in general, either annual or for a term of ſeven years, at an annual premium; and the offices, as an indulgence to the inſured, generally allow fifteen days from the expiration of each year for the payment of the premium for the next ſucceeding year. But the inſured has always been conſidered as being under the protection of the policy till the expiration of the fifteen days, provided the premium were paid within that time. Several offices now hold themſelves liable for any loſs during the fifteen days that are allowed for the payment of the renewed premium upon annual policies, and others for a longer period; but every policy for a ſhorter period than a year ceaſes at ſix o'clock in the evening of the day that is mentioned in it. A policy of inſurance, being a choſe in action, is, in ſtrictneſs, not aſſignable at law; but it may be aſſigned in equity. However, the mere aſſignment of the policy would be of little avail without an aſſignment of the ſubject-matter of the inſurance alſo. In the printed propoſals of all the offices, it is declared, that, upon the death of an inſured, his intereſt in the policy ſhall be continued to his repreſentative to whom the property inſured belongs, provided that ſuch repreſentative, before any new payment be made, procure his right to be indorſed on the policy at the office. The policies of the Contribution Societies, *viz.* the "Hand in Hand," "Union," and "Weſtminſter," may be aſſigned, without any expreſs permiſſion from the reſpective offices for that purpoſe; and it is ſufficient if the aſſignment be brought to the reſpective offices to be entered. But the other offices give notice, generally upon the policy, that it ſhall be of no force if aſſigned, unleſs ſuch aſſignment be allowed by an entry in the books of the office, or indorſed on the policy: and hence it ſeems to be a ſettled rule in all the offices, not to allow any transfer of any policy without the conſent of the managers. If an aſſignor of the property inſured undertake to get the policy transferred to the aſſignee, he will be liable to an action for neglecting to do it; even though his undertaking was merely gratuitous. For the proof and recovering of loſs, the following article is found in the propoſals of ſeveral of the offices, importing, "that perſons inſured ſuſtaining any loſs or damage by fire, are forthwith to give notice thereof at the office, and, as ſoon as poſſible afterwards, deliver in as particular an account of their loſs and damage as the nature of the caſe will admit of; and make proof of the ſame by their oath or affirmation, according to the form practiſed in the ſaid office; and by their books of accounts, or other proper vouchers, as ſhall be reaſonably required; and procure a certificate under the hands of the miniſter and churchwardens, together with ſome other reputable inhabitants of the pariſh not concerned in ſuch loſs, importing, that they are well acquainted with the character and circumſtances of the perſon or perſons inſured, and do know, or verily believe, that he, ſhe, or they, really and by misfortune, without any fraud or evil practice, have ſuſtained by ſuch fire the loſs and damage, as his, her, or their loſs, to the value therein mentioned. But till ſuch affidavit or certificate of ſuch inſured's loſs ſhall be made and produced, the loſs-money ſhall not be payable. And if there appears any fraud or falſe ſwearing, ſuch ſufferers ſhall be excluded all benefit by their policies." In the policies of theſe offices the inſurers undertake to pay the loſs, not exceeding the ſum inſured, "according to the exact tenor of their printed propoſals," deſcribing their propoſals by their reſpective dates.

Inſurances againſt fire are deſcribed in the plans and propoſals of the different ſocieties, with little variation, as *common*, *hazardous*, and *doubly hazardous*; and they comprehend buildings and goods. *Buildings* ſubject to *common* inſurances are thoſe of brick or ſtone, ſtanding alone, or ſeparated by partition walls, and covered with ſlate, tile, copper, lead, or iron, with brick chimnies; in which no hazardous trades are carried on, or hazardous goods depoſited. *Goods* are houſhold goods, in private dwellings, merchandize and ſtock, not hazardous, in brick or ſtone buildings as above deſcribed, and in which no hazardous trades are carried on, nor hazardous goods depoſited. *Hazardous* inſurances comprehend *buildings* of timber or plaſter, brick and timber, or brick and ſtone, not having party walls of brick or ſtone, wherein no hazardous trades are carried on, or hazardous goods depoſited, brick or ſtone buildings in which hazardous trades are carried on, or hazardous goods depoſited; alſo thatched barns and out-houſes (having no chimnies, or adjoining to any building having a chimney), containing farmer's ſtock or implements of huſbandry: likewiſe all ſhops and warehouſes which have German or metal ſtoves with pipes. *Goods* ſubject to the ſame kind of inſurance are the ſtock and goods of bread-bakers, brewers, vinegar and ſweet-makers, printers, hot-preſſers and calenderers, carpenters, chemiſts, coach-makers, colour-men, coopers, hemp and flax-dreſſers, innholders, malthouſes, oil leather-dreſſers, ſhip and tallow-chandlers, ſtable-keepers, pawn-brokers, hemp, flax, pitch, tar, turpentine, roſin, tallow, hay, ſtraw, and all manner of fodder, and corn unthraſhed, apothecaries' ſtock; alſo, oil and ſpirituous liquors, as merchandize and the ſtock in timber-yards. *Doubly hazardous* inſurances comprehend *buildings* which are thatched, alſo timber or plaſter buildings, in which hazardous goods are depoſited, or hazardous trades carried on; and *goods* or ſtock in thatched dwellings; alſo ſalt-petre, working-perfumers, tallow-melters, wax-chandlers, ſpermaceti candle-makers, and rope-makers in brick and tiled buildings, boat-builders, china, glaſs, or earthen wares.

The "Hand in Hand Fire-office" was inſtituted in the year 1696; and its terms are, for *common* inſurances, 3000*l.* or under, 2*s. per cent. per annum:* for *hazardous* inſurances, 3000*l.* or under, 3*s. per cent. per annum:* for *doubly hazardous* inſurances, 3000*l.* or under, 5*s. per cent. per annum.* If inſurances are deſired for any larger ſums than are ſpecified in the table of premiums, a ſpecial agreement may be made for the ſame, and alſo for particular buildings, goods, &c. not included in the ſecond and third articles above enumerated. Perſons inſuring in this office are allowed one year's premium and duty, and muſt pay the requiſite premiums and depoſit according to the nature of the riſk. They become joint proprietors and members of the ſociety, and are entitled to a proportionate ſhare of the profits.

The "Union Fire-office" was inſtituted in 1714, for inſuring houſes and buildings, goods, merchandize, and ſhips in harbour, in dock, or while building, from loſs or damage by fire. The ſeptennial inſurances are allowed one year's premium and duty, and become proprietors, partaking of the profits of the ſociety. The annual or ſhort period inſurers are completely protected from any loſs or damage by fire, or from any call or contribution towards any loſs or damage happening to others, by a very ample fund which has been raiſed for that purpoſe.

TABLE OF ANNUAL PREMIUMS.

(Excluſive of Government Duty.)

	Common.	Hazardous.	Doubly Hazardous.
£.	£. s. d.	£. s. d.	£. s. d.
On ſums not exceeding 3000	0 2 0 *per cent.*	0 3 0 *per cent.*	0 5 0 *per cent.*
——— 6000	0 2 6 *per cent.*	0 4 0 *per cent.*	0 6 0 *per cent.*
Larger Sums may be inſured by ſpecial Agreement.			

No charge is made for policies of 300*l.* and upwards. Farming ſtock may be inſured at 2*s. per cent.*. The "Royal Exchange Aſſurance," of which we have given an account, as far as it is a life-inſurance office, under ASSURANCE, inſures alſo from loſs or damage by fire.

TABLE OF ANNUAL PREMIUMS.

(Not including Duty.)

Common Aſſurances.	Hazardous Aſſurances.	Doubly Hazardous Aſſurances.
Not exceeding 3000*l.* 2*s. per cent.*	Not exceeding 2000*l.* 3*s. per cent.*	Not exceeding 2000*l.* 5*s. per cent.*
Larger Sums may be aſſured by ſpecial Agreement; and Farming Stock at 2*s. per cent.*		

The corporation of the "London Aſſurance" inſures houſes and goods from fire, and alſo inſures lives. (See ASSURANCE.) The premiums are as follows:

Common Aſſurances.	Hazardous Aſſurances.	Doubly Hazardous.
Sums not exceeding 10,000*l.* 2*s. per cent.*	Sums not exceeding 3000*l.* .... 3*s.* 0*d. per cent.*	——— 5*s. per cent.*
—— above 10,000*l.* 2*s.* 6*d.*	Above 3000*l.* and not exceeding 5000*l.* 3*s.* 6*d.*	Farming Stock, 2*s.* with average clauſe.
	Above 5000*l.* .... 4*s.* 0*d.*	

Perſons aſſuring for ſeven years, will be allowed one year's premium, and duty; for ſix years, 10 *per cent.* on the premium; for five years, 8 *per cent.*; for four years, 6 *per cent.*; for three years, 4 *per cent.*; for two years, 2 *per cent.*

Premiums of aſſurance from fire for ſhips in harbour, building, or repairing, or for cargoes, or for veſſels and other craft employed in inland navigation, and goods, &c. laden thereon.

		For one Year.	For ſix Months.	For three Months.	
	£.	*s.* *d.*	*s.* *d.*	*s.* *d.*	
Sums not exceeding	10,000	3 0	2 6	2 0	*per cent.*
Above	10,000	4 0	3 0	2 6	

Five *per cent.* diſcount allowed on premium. The premium on goods, hazardous or not hazardous, in any of the warehouſes or ſheds, or on the open wharfs, or in any part of the port of London, within five miles of the Royal Exchange (the Weſt India docks excepted), with the average clauſe, 5*s.* *per cent.*; on goods not hazardous, ſimilarly ſituated, 3*s.* *per cent.* The average clauſe, ſo often referred to, is as follows: It is agreed, that if the goods aſſured ſhall be of greater value than the ſum aſſured, and the ſame ſhall not be totally conſumed, the inſurer ſhall only be liable to pay ſuch a proportion of the loſs as the ſum aſſured ſhall bear to the whole value of the goods at the time of the breaking out of any fire. On ſums of 300*l.* and upward, the policy and mark are allowed gratis.

The "Sun Fire-office" was eſtabliſhed in the year 1710, and inſures againſt loſs or damage by fire, upon the following terms.

Table of Rates.

Annual Premiums to be paid for Inſurances.				
Sums not exceeding	10,000	Common	2*s.* *per Cent.*	Sums above may be inſured by Special Agreement.
	6,000	Hazardous . . .	3*s.* Ditto.	
	3,000	Doubly Hazardous .	5*s.* Ditto.	
Farming Stock, on any Part of the Farm, inſured under General Policies, without the Average-Clauſe, at 2*s.* *per Cent.*				
N. B. Any barn, or other out-building, and the farming ſtock therein, may be inſured under one ſum:—premium 3*s.*				

Perſons may inſure for more years than one, not exceeding ſeven; and, in ſuch caſe, there will be an abatement of ſix-pence in the pound per annum, on the premiums agreed for, for every year except the firſt: In a common inſurance of 1000*l.* for ſeven years, the premium to be paid, by the table, will be ſeven pounds, in which the ſix-pence in the pound per annum is to be deducted for the laſt ſix years, that is, three ſhillings and ſix-pence per annum, which amounts to one pound one ſhilling, and reduces the ſum to be paid to five pounds nineteen ſhillings, and the ſame in proportion for any other ſum or number of years; and perſons inſuring can never be ſubject to any calls or contributions to make good loſſes.

The "Sun Life Aſſurance Society" grants annuities, makes aſſurances on lives and ſurvivors, and provides for the endowment of children; on the terms, and in the manner of other offices for inſuring lives.

"The Weſtminſter Fire-office" was eſtabliſhed in the year 1717. The terms are, in the firſt claſs of common inſurances, for any ſum not exceeding 10,000*l.*, 2*s.* *per cent.* *per annum*; in the ſecond claſs of hazardous inſurances, for any ſum not exceeding 6000*l.*, 3*s.* *per cent.* *per annum*; in the third claſs of doubly hazardous inſurances, for any ſum not exceeding 3000*l.*, 5*s.* *per cent.* *per annum.* The fourth claſs includes inſurances by ſpecial agreement. Every ſeptennial inſurer becomes a member of the ſociety, and ſhall be allowed one year's premium; he will alſo have a proportionable ſhare of the profits, and be liable to contribute to loſſes, but not to exceed 10*s.* *per cent.* on the firſt; 15*s.* on the ſecond; and 20*s.* on the third claſs of inſurances.

The "Phœnix Fire-office" was eſtabliſhed in 1782; and its premiums are for common inſurances, for ſums not exceeding 3000*l.*, 2*s.* *per cent.* *per annum*; for hazardous inſurances, for ſimilar ſums, 3*s.* *per cent.* *per annum*; and for double hazardous inſurances, the ſums being the ſame, 5*s.* *per cent.* *per annum.* Hay and corn in barns or ſtacks, and other farming ſtock, may be inſured at 2*s.* *per cent.* *per annum.* Ships, barges, and all kinds of water-craft; alſo, cargo on board may be inſured at 3*s.* *per cent.* *per annum*, for ſums not exceeding 3000*l.* Inſurances on larger ſums, and on goods, &c. peculiarly hazardous, may be effected by ſpecial agreement. Perſons chuſing to inſure for ſeven years, will be charged for ſix years only; and for any number of years, more or leſs than ſeven, will be allowed a reaſonable diſcount both on the premium and the inſurance tax.

"The Globe Inſurance" was eſtabliſhed in 1803, and comprehends the granting inſurances againſt loſs or damage by fire, on lives and ſurvivorſhips, the endowment of children, and immediate, deferred, and progreſſive annuities. This office makes common inſurances at an annual premium of 2*s.* *per cent.*; hazardous inſurances at 3*s.* *per cent.*; and doubly hazardous inſurances at the annual premium of 5*s.* *per cent.* Farming ſtock is inſured at 2*s.* *per cent.*; and this may be inſured for three, ſix, or nine calendar months at certain ſtipulated rates. Policies are allowed in all caſes where the annual premium amounts to 6*s*. Inſurances for ſeven years are charged only ſix years premiums; and a conſiderable reduction is made on country inſurance. The inſurances on lives and on ſurvivorſhip are made at the rates of other offices; nor does the company require entrance money, or admiſſion fees, from perſons effecting life inſurances. The capital of the company is ſtated to be one million ſterling, the whole of which has been inveſted in government or real ſecurities, and it is ſtipulated that no members of the company ſhall be liable to pay any ſum beyond the amount of his ſubſcription or ſhare in the ſaid capital of one million.

The "Imperial Fire-office" was eſtabliſhed in 1803. Its capital, of one million two hundred thouſand pounds ſterling, has been ſubſcribed in ſhares of 500*l.* each; and no member is a ſubſcriber for more than 5000*l.* Each member has depoſited 10*l. per cent.* on the amount of his ſubſcription, amounting in the whole to 120,000*l.* which ſum is inveſted, and to accumulate for five years, without dividends to the members of the company. In caſe the current premiums on inſurances, with the depoſit of 120,000*l.* and all its accumulations, ſhall prove inadequate to ſatiſfy the loſſes which may ariſe, the members of the company are, from time to time, to be called upon for farther ſums, in proportion to their ſubſcriptions, and even to their full extent, if neceſſary. If the current premiums ſhall be more than ſufficient to anſwer loſſes, and the expences of management, the ſurplus is, from time to time, to be inveſted; but ſuch profits are in no event to be divided, but are to be applied for augmentation of the capital ſtock; and the dividends and intereſt of the profits only are to be divided, after the expiration of five years. The premium in common inſurances is 2*s. per cent. per annum* for 3000*l.* and under; in hazardous inſurances, 3*s. per cent. per annum*, for 1000*l.* or under; and in double hazardous inſurances, 5*s. per cent. per annum*, for 1000*l.* or under. Perſons chuſing to inſure for ſeven years will be charged for ſix years only; and for any number of years, leſs than ſeven, will be allowed a reaſonable diſcount, both on the premium and duty.

The "Albion Fire and Life Inſurance Company" was inſtituted in the year 1805; and is ſtated to poſſeſs a capital of one million ſterling. Its inſurance againſt loſs or damage by fire is in the firſt claſs of common inſurances 2*s per cent. per annum*, to the amount of 3000*l.*; in the ſecond claſs of hazardous inſurances, 3*s. per cent.* annually; and in the third claſs of doubly hazardous inſurances, 5*s. per cent. per annum* both to the ſame amount. Inſurances are taken to a larger amount than that above ſtated; and policies are granted at ſuitable premiums for leſs than 12 months. On inſurances for ſeven years, or for any greater or leſs term, exceeding one year, a conſiderable allowance is made, both on the premium and duty. The following abatements are made on the premiums of fire inſurances of the firſt claſs, out of London; *viz.* 25 *per cent. per annum* on policies for ſingle years; 30 *per cent.* on policies for three years; 35 *per cent.* on policies for five years; 40 *per cent.* on policies for ſeven years; and in the like proportion for policies for other periods. Inſurances on lives are conducted on the ſame terms with thoſe of other offices of a ſimilar kind. No admiſſion fine is charged on life inſurance.

The "Britiſh Fire Office" inſures houſes and goods in the three claſſes above ſpecified at 2*s.*, 3*s.*, and 5*s. per cent. per annum* reſpectively.

The "Hope Fire and Life Inſurance Company" was inſtituted in 1807. Its annual rates of inſurance on the three claſſes above recited are, 2*s. per cent.*, 3*s. per cent.*, and 5*s. per cent.* on ſums not exceeding 10,000*l.*, 6000*l.*, and 3000*l.*, reſpectively. Farming ſtock is inſured at 2*s. per cent.* on a ſum not exceeding 10,000*l.* Special riſks may be inſured on terms correſponding to them. The following abatements are made upon country aſſurances, *viz.* 10 *per cent.* on policies for a ſingle year; 15 for three years; 20 for five years; 25 for ſeven years. Every perſon not being a proprietor of a ſhare or ſhares in the company, and who ſhall inſure or procure to be inſured, property to the amount of 1000*l.*, ſhall, upon the payment of 5*l.* beyond the premium of inſurance, be entitled, out of the profits (ariſing from fire inſurance only) to ſuch intereſt or dividend as may ariſe and become payable on one 50*l.* ſhare in the capital ſtock of the company; and ſo on in like manner for every additional 1000*l.* ſo inſured; and ſuch intereſt or dividend ſhall continue to be paid to ſuch perſon or perſons, or to his or their legal repreſentative or repreſentatives, during ſuch period as ſuch inſurances ſhall continue to be effected, and in the event of the ſame being diſcontinued, all dividends and intereſt, which may be then due or payable, together with the ſum of 5*l.* ſo paid for every 1000*l.* ſo inſured as aforeſaid, ſhall be forfeited and become the property of the company. Life inſurances are effected by this company on the ſame terms with thoſe of other offices. Perſons not being proprietors, who inſure, or procure to be inſured, 500*l.* upon their own lives, or lives of others, will, upon the payment of ten ſhillings *per cent.* (on the admiſſion of the party) beyond the premium paid for the inſurance, be entitled, out of the profits of the life fund, to ſuch intereſt or dividend as may be paid on a 50*l.* ſhare to the ſeveral proprietors thereof, and ſo on in like manner for every 500*l.* ſo inſured; but in no caſe whatever are they to be reſponſible for any claims which the life fund may be called upon to pay, the capital of the company being of a ſufficient magnitude for that purpoſe.

The "Eagle Inſurance Company" was inſtituted in 1807, for fire and life inſurance, and for granting annuities. Its capital is ſtated at two millions ſterling. The annual rates of inſurance againſt fire are as follows:

Annual Rates of Inſurance.

	s.	*d.*	
Common Inſurance, not exceeding 10,000*l.*	2	0	*per cent.*
Above	2	6	
Hazardous ditto, not exceeding 6000*l.* .	3	0

Farming Stock.

		s.	*d.*	
Without average clauſe,	for three months	1	3	*per cent.*
	for ſix months	1	6	
	for any longer period, not exceeding 12 months	2	0	

The building and ſtock of ſugar refiners, ſugar grinders, ſea biſcuit bakers, diſtillers, muſical inſtrument makers, cotton-ſpinners, calico printers, flax dreſſers, and other extraordinary riſks, may be inſured by ſpecial agreement.

Policies for ſhort periods, or leſs than a year, may be effected at conſiderably reduced premiums, and will pay only a proportionable part of the duty. The inſurance on lives is conducted as in other offices.

The "County Fire Office" was eſtabliſhed in 1807, for the expreſs benefit of country reſidents. The diſtinguiſhing principles of this inſtitution are, that its buſineſs conſiſts of a ſelection of the beſt riſks; that the perſons inſured become members; that all the members ſhare the profits equally, according to the ſums which they reſpectively contribute during ſeven years (whether their policies be taken out originally for ſeven years, or be renewed annually), and with the important advantage of not being liable to make good the loſſes of others, as a ſurplus capital of 400,000*l.* has been provided to meet any exceſs of loſſes that may occur. In common inſurances of 5000*l.* and under, in one riſk, the annual premium is 2*s. per cent.*; in hazardous inſurances, of 3000*l.* and under, in one riſk, 3*s. per cent.*, above 3000*l.* and under 5000*l.*, 4*s. per cent.*; in doubly hazardous inſurances, 3000*l.* and under, in one riſk, 5*s. per cent.*, above 3000*l.* and under 5000*l.*, 7*s. per cent.* Larger inſurances, according to the above deſcription of riſks, may be made by ſpecial agreement: and other inſurances againſt more hazardous riſks may be ſettled in the ſame manner. Hay, corn, and other agricultural ſtock, of whatever deſcription, on any part of a farm, may be inſured in one general ſum, at the reduced rate of 2*s. per cent.* without the average clauſe. Perſons inſuring for ſeven years will be charged only for ſix; and for any number of years more or leſs than ſeven, diſcount will be allowed both on the premium and duty. All the offices inſure againſt fire by lightning. It will be remembered, that a duty of 2*s.* 6*d. per cent. per annum*, on all property inſured from fire, is payable to government, under an act of the 44th of George III.

The "Atlas Aſſurance Company" was eſtabliſhed in 1808, and undertakes to aſſure the proprietors of buildings, merchandize, furniture, farming ſtock, goods and effects, and alſo of craft and ſhipping upon canals and in harbour, againſt loſs by fire; and alſo grant aſſurance upon lives. The capital is ſtated at one million two hundred thouſand pounds, of which the ſum of 120,000*l.*, inveſted in government or real ſecurities, will be applicable to the immediate purpoſes of the inſtitution; and the remainder guaranteed under a deed of ſettlement by a numerous and reſpectable proprietary.

Rates of Aſſurance per Annum.

Riſks.	Quality.	*Per Cent.*		On Sums not exceeding—	
		s.	*d.*	£.	
Firſt . . .	Not Hazardous	2	0	5000	Unleſs by Special Agreement.
Second . .	Hazardous	3	0		
Third . . .	Doubly Hazardous	5	0	3000	
Fourth . .	Farming Stock	2	0	5000	
Fifth . . .	Riſks, to which none of the above rates will apply.—Theſe may be aſſured by Special Agreement, on Terms as moderate as the nature of them will permit.				
	N. B. An additional premium of Sixpence *per cent.* will be required on buildings or goods within the Water-Side Diſtrict, for extra riſk.				

No charge is made for policies or indorſements on them: and for the encouragement of perſons making aſſurance for ſeven years by one payment, a deduction of one-ſeventh part of the premium and duty will be made; and if at the end of that period a further aſſurance of ſeven years be effected on the ſame property, a deduction of one-fifth part of the premium, and ſo on for ſucceeding years. The terms of life-aſſurances are much the ſame as thoſe of other offices.

A Table, exhibiting the Amount of the Duty on Inſurances for the Year 1810.

INTACTÆ, right lines to which curves do continually approach, and yet can never meet with them; more uſually called *aſymptotes*.

INTAGLIOS, precious ſtones, having the heads of great men, inſcriptions, and the like, engraven on them; ſuch as we frequently ſee ſet in rings, ſeals, &c.

IN-TAKER, a name anciently given to certain banditti, or free-booters, who inhabited part of the North of England, and made frequent incurſions into the very middle of Scotland; plundering the inhabitants wherever they came.

Thoſe who made the expeditions, were called *out-parters;* and thoſe who were left behind to receive the booty, *in-takers*. 9 Hen. V. c. 7.

INTAVOLARE, *Ital.* to write muſic for the lute and guitar in tablature, inſtead of muſical characters. See Tablature and Time-table.

INTAWA, in *Geography*, a town of Hindooſtan, in Bundelcund; 15 miles E. of Pannah.

INTEGERS, in *Arithmetic*, denote whole numbers; in contradiſtinction to fractions.

Integers may be defined to be, numbers which refer to unity, as a whole to a part.

INTEGRAL, or Integrant, is applied by the ſchoolmen to thoſe parts which are neceſſary to the integrity of a whole. In which ſenſe they ſtand contradiſtinguiſhed from *eſſential* parts.

Thus the arms, legs, &c. are integral parts; body and ſoul, eſſential parts of a man.

Integral *Calculus*, in the *New Analyſis*, is the counter part to the differential calculus.

This laſt has been completely explained by the marquis De l'Hoſpital; but the other ſtill remains imperfect, having been yet but little cultivated.

The integral calculus of Leibnitz, and other foreigners, anſwers to what the Engliſh call *inverſe method of fluxions*. See Fluxions, and Calculus.

INTEGRANT Parts, in *Philoſophy*, the ſimilar parts of a body, or parts of the ſame nature with the whole; as filings of iron are the integrant parts of iron, and have the ſame nature and properties with the bar they were filed off from. The chemiſts diſtinguiſh, in their reſolutions of bodies, between the dividing and reſolving them into integrant parts like theſe, and what they call conſtituent parts; that is, diſſimilar parts, or the principles of the bodies they work upon. Thus when crude mercury is diſſolved in aquafortis, though held imperceptibly in the menſtruum; yet when that menſtruum is diluted with water, and a copper-plate is ſuſpended in it, the menſtruum leaves the mercury, to work upon the copper, and the mercury ſubſides unaltered and in its own natural form; the mercury, therefore, in this operation, was only divided into its integrant parts, or ſmall parcels of the ſame nature and properties of the whole; but when artificial cinnabar is reſolved or divided into crude mercury and ſulphur, neither of theſe are of the ſame nature and properties with the cinnabar, and are not its integrant but its conſtituent parts. This therefore is the dividing a body into its conſtituent parts or principles.

INTEGRITY *of the Action*. See Action.

INTEGRUM Folium, among *Botaniſts*. See Leaf.

Integrum, *in reſtitutio*. See Restitution.

INTEGUMENTS, in *Anatomy*, the coverings of the body; the word is generally employed with the epithet *common*, as they are of the ſame nature and number in all parts of the frame. They conſiſt of the cuticle or epidermis, with its appendages the nails, of the rete mucoſum, and of the true ſkin, cutis, or dermis. The hair in its nature ſeems to reſemble the cuticle; but it grows from the cutis. To theſe three layers a fourth is ſometimes added, under the name of the *adipous membrane*. In truth, the ſkin is always connected to the ſubjacent organs by cellular tiſſue, the interſtices of which in moſt caſes contain fat, but not invariably ſo. This connecting ſtratum belongs entirely to the cellular organ. See Cellular *Subſtance*.

To the technical expreſſion of common integuments, the word ſkin correſponds in common language; but this term is often uſed by anatomiſts to denote the cutis, in oppoſition to the cuticula.

The three parts compoſing the integuments of the body are ſo different in their organization and functions, that we cannot approve the common arrangement, by which they are all conſidered together as forming one organic ſyſtem. We prefer the method of Bichat, who deſcribes the cutis, with the mucous layer on its ſurface, under the name of the *dermoid* ſyſtem; the cuticle with the nails under that of *epidermoid* ſyſtem; and the hairs under that of *hairy* ſyſtem (ſyſtème pileux). We ſhall employ this diviſion, and derive our account of the ſubject chiefly from the Anatomie Generale of that writer.

Dermoid Syſtem.—The ſurface of the body is covered in all animals by a more or leſs denſe membrane, generally proportioned in its thickneſs to the volume of the body, and ſerving the purpoſe of protecting the ſubjacent organs, of ſeparating a conſiderable portion of the reſidue of nutrition and digeſtion, and eſtabliſhing the relations between us and ſurrounding objects. In man it is the ſenſitive limit of his frame, placed at the extremity of his ſentient powers, inceſſantly expoſed to external impulſes, thus giving riſe to the relations of his animal life, and connecting his exiſtence to that of external objects. This covering is the ſkin or cutis.

Being every where proportioned to the external parts over which it is applied, it follows their chief inequalities, rendering the large projections very ſenſible, but concealing a great number of the ſmaller: hence the different appearances of the body in its entire and flayed ſtates. It is continuous throughout, and reflected at the different openings into the interior of the body, giving origin to the mucous ſyſtem. The limits of the two ſyſtems are conſtantly marked by a reddiſh line, the mucous being within, and the dermoid on the outſide of that boundary. The demarcation, however, is not ſo decided in the organization as in the colour; they appear to be inſenſibly blended. The dermoid ſyſtem becomes thinner in the neighbourhood of theſe openings, particularly about the face. At their commencement the mucous organ borrows more or leſs of the characters of the dermoid.

The external ſurface of the dermoid ſyſtem is every where contiguous to the epidermis, and is remarkable on account of the hairs implanted in it, of the oily matter which habitually covers it, of the ſweat which is depoſited on it, and of the ſenſe of touch reſiding in it. We ſhall diſregard theſe points at preſent, and confine ourſelves to the conſideration of the external forms of the ſyſtem.

Various kinds of folds are ſeen on the external ſurface.

1. Some depend on certain ſuperficial muſcles, which, adhering cloſely to the dermis, and almoſt conſolidated to its ſubſtance, throw it into wrinkles when they contract. Such are the wrinkles of the forehead produced by the epicranius; the radiated folds round the eyelids formed by the orbicularis; thoſe of the cheeks by the zygomatici and levator anguli oris; thoſe round the mouth when the lips are contracted by the orbicularis oris, &c. Theſe folds ariſe from the circumſtance that the ſkin cannot contract

as the muſcles do; and they are of the ſame nature with what we obſerve in mucous ſurfaces, particularly in the ſtomach, when the contiguous muſcular plane is contracted. Hence their direction is always perpendicular to that of the ſubjacent muſcles, whoſe fibres they cut at right angles. As the motions of theſe parts in the human countenance are much influenced by the paſſions, the wrinkles and irregularities in the face are highly important in a phyſiognomical point of view. The repeated actions of particular muſcles, under the habitual impreſſion of particular paſſions, produce permanent lines, which give the character of the individual.

2. Other wrinkles ariſe from the motions of parts, but not from thoſe of the ſubjacent muſcles: ſuch are thoſe of the palm and ſole. Here there is no ſub-cutaneous muſcle adhering to the ſkin, except the palmaris brevis, which has no ſhare in producing the folds, where the ſkin is habitually modified by the flexion of the organ. To this claſs belong the impreſſions at the articulations of the phalanges. In the palm there are three principal ones: at the baſis of the thumb, produced by the motion of oppoſition of that organ, at the front of the palm, by the flexion of the fingers, and in the middle of the palm. The cutis forms folds in theſe depreſſed lines when the palm is rendered hollow. Numerous other ſmall folds, correſponding to leſs marked and frequent motions, cut the former at various angles.

In the back of the foot and hand we obſerve numerous wrinkles at each articulation of the phalanges, when they are extended: they diſappear on flexion, and ariſe from the ſkin being looſer and more copious in theſe parts to accommodate the motions. There are analogous folds at moſt of the articulations, but they are leſs ſtrongly marked, becauſe the ſkin is leſs adherent to the neighbouring organs. Over the whole trunk, on the arm and fore-arm, the leg and thigh, no depreſſions are obſerved except thoſe produced by muſcular prominences.

3. A third kind of wrinkles, or rather of cutaneous impreſſions, which are very inconſiderable, occurs particularly in the ſole and palm, where they are eaſily diſtinguiſhed from the foregoing. They indicate the rows of papillæ: and nothing of the kind occurs on the ſurface of the trunk.

4. Laſtly, there are the wrinkles of old age, the nature of which is quite different. When the ſub-cutaneous fat has begun to diſappear, the ſkin is too large for the parts which it covers: it loſes its contractility by age, and cannot therefore accommodate itſelf to the altered bulk of parts. Thus, where there was moſt fat, as in the face, the wrinkles are moſt ſtrongly marked. When young perſons are ſuddenly emaciated, the ſkin contracts, and no wrinkles enſue.

The internal ſurface of the ſkin correſponds every where to the cellular tiſſue, which is looſe on the trunk, the thighs, arms, &c. and more denſe on the cranium, hand, &c. In moſt animals, a muſcular plane, named panniculus carnoſus, and analogous in its form to that which is every where connected to the mucous membranes in man, ſeparates the ſkin from the other organs, and imparts to it various motions. Traces of ſuch a ſtructure occur in a few inſtances in man, as in the latiſſimus colli, the epicranius, and the muſcles of the face.

The cellular tiſſue connects the cutis to muſcles almoſt univerſally in the trunk; but it has nothing to do with the motions of theſe muſcles, and receives from them no ſenſible influence. It is ſeparated from the muſcles in the limbs by aponeuroſes. Many veſſels purſue their courſe under it: large veins may be obſerved through its ſubſtance; numerous arterial ramifications are diſtributed on its ſurface; and nerves are found among theſe.

Organization of the Dermoid Syſtem.

1. *Proper Tiſſue of this Syſtem.*—This comprehends, 1ſt, the corion; 2dly, the rete mucoſum; and, 3dly, the papillæ or villi. The corion is the eſſential part, which determines the thickneſs and form of the ſkin: the rete mucoſum is not very diſtinct from it; and the papillæ manifeſtly grow out of it.

The corion is always white in the human ſubject. Its thickneſs varies conſiderably. In the head it poſſeſſes oppoſite characters on the cranium and the face: in the former it is very thick and denſe in its texture, in conſequence of the numerous hairs which traverſe it: in the latter it is every where thin and delicate, but more particularly in the eyelids and lips. On the poſterior part of the trunk, and eſpecially along the back, its thickneſs is nearly double that which it has in front, where it is nearly uniform in the neck, cheſt, and abdomen. We muſt except, however, the penis, ſcrotum, labia, and breaſts, where its texture is much thinner. The corion is nearly of equal thickneſs in the ſhoulder, arm, and fore-arm; in the hand its thickneſs is rather increaſed, and more ſo in the palm than on the back. It is generally much thicker on the thigh and leg, where there are more bulky muſcles than in the arm and fore-arm. It grows thicker in the foot, but leſs ſo in the dorſal than in the plantar region, which is the thickeſt part of the ſyſtem. The relation of its functions to the various degrees of thickneſs obſerved in the hand, foot, and cranium, may be eaſily underſtood; but in other parts we do not clearly ſee the reaſon of theſe differences.

It is generally thinner in women than in men, ſo as to preſent a ſenſible difference when the two are contraſted in any region of the body.

In order to examine the interior ſtructure of the corion, it ſhould be carefully ſeparated from the cellular and adipous tiſſue, to which the inner ſurface adheres more or leſs cloſely: we ſhall then find that ſurface differently diſpoſed in the different regions.

1. In the ſole and palm we ſee an infinite number of whitiſh fibres, ſhining like thoſe of an aponeurotic nature, detached from the inner ſurface of the ſkin, decuſſating each other in every direction, leaving, particularly towards the heel, numerous areolæ of different ſizes filled with fat, and gradually loſt in the ſub-cutaneous tiſſue. Hence there is not the ſame mobility of the ſkin over the covered parts, on theſe ſurfaces, as in moſt other ſituations; an arrangement well ſuited to the functions of prehenſion and ſupport belonging to theſe parts.

2. The cutis of other parts of the body has theſe fibres much leſs diſtinct, not interwoven with the cellular tiſſue, and ſeparated by ſmaller areolæ: hence it is much looſer, and more eaſily diſſected from the ſubjacent parts. The areolæ repreſent a vaſt number of openings placed irregularly by the ſide of each other, and lodging ſmall maſſes of fat: when theſe are carefully removed very ſenſible vacuities are left. The fibres, which form them, are ſufficiently cloſe to give the appearance of an uniform ſtructure perforated by numerous apertures. Theſe areolæ are very favourable to the action of the tanning principle, which is introduced through them to the corion much more effectually than it can penetrate on the oppoſite ſide. Bichat aſcertained this point by a direct experiment on the human ſkin. Chaptal has obſerved that the epidermis is a real obſtacle to the action of tanning, and that its removal, with that of the hair, is an eſſential preliminary for this reaſon; but that the hide, even when thus prepared, is affected much more eaſily on the inner than on the outer ſide.

3. On the back of the hand and foot, as well as on the forehead, the corion does not exhibit theſe numerous openings on its inner ſurface; it is ſmooth and whitiſh, particularly after being macerated a little: the ſame obſervation may be made concerning that of the ſcrotum, prepuce, and labia. Its tiſſue is more compact, and exhibits no intervals; ſo that although it is thinner than on the limbs and trunk, it contains nearly as much ſubſtance. In that, which correſponds to the hair and beard, we obſerve only the openings neceſſary for the tranſmiſſion of thoſe parts.

The three great modifications in the organization of the ſkin, which we have juſt deſcribed, are merely differences of form, and not in the eſſential nature of the organ. The areolæ may be ſeen in all parts, where they exiſt at all, by means of maceration, which is a very good method of examining the ſtructure of the ſkin. Immerſion in water ſoftens the ſkin by ſeparating the fibres of its corion, and rendering their intervals more diſtinct: we then find that the areolæ are not confined to the internal ſurface, but are prolonged into its ſubſtance, which is penetrated by them in its whole thickneſs. Theſe areolæ do not terminate in cul-de-ſacs towards the external ſurface, but they open on that ſurface by numerous holes very apparent in ſkin, which has been macerated for a month or two. The epidermis muſt be removed in order to render them ſenſible: they penetrate the ſkin obliquely, and admit in ſome parts and ſome ſubjects the introduction of a pin's head. They are ſimple communications from the interior to the exterior for the paſſage of hairs, exhalants, and abſorbents, as they come to the ſurface: thus the ſubjacent areolæ are merely cells containing the blood-veſſels, and the tiſſue of the ſkin altogether is a true cellular net-work, of which the interſtices are very diſtinct on the inſide, but leſs obvious externally. Thus the corion conſtitutes the baſis or ſkeleton of the cutaneous organ, lodging in its areolæ all the other parts of the organ, and giving to them their proper form.

Bichat conſiders that the areolar tiſſue, which compoſes the corion of the ſkin, has much analogy with that of the fibrous ſyſtem. Its denſity and reſiſtance are nearly the ſame in the heel: it becomes yellowiſh and tranſparent by boiling; it reſiſts maceration for a long time; and it receives in ſome ſituations the inſertion of muſcular fibres. Yet the ſenſibility and the diſeaſes of the two ſyſtems differ altogether.

The acute ſenſibility of this organ does not reſide in the areolar tiſſue of its inner ſurface, but in the part containing the papillæ. And we find that the ſame part is the ſeat of moſt cutaneous eruptions. The external ſurface only is coloured by the blood in eryſipelas; and hence ſlight preſſure, by driving this fluid into the deeper veſſels, removes the red colour. In meaſles, ſcarlet-fever, &c. the redneſs is alſo ſuperficial. Injections occaſion much greater redneſs of the external than of the internal ſurface; as the arterial trunks are found in the latter, and the numerous exhalants in the former. Theſe conſiderations prove clearly that the cellular tiſſue of the ſkin has much leſs vital activity than its outer ſurface; that this tiſſue is foreign to almoſt all the great phenomena occurring in the ſkin, particularly thoſe of ſenſation and circulation, which take place in the papillæ and the reticular body. Its functions, like thoſe of the fibrous ſyſtem, ſuppoſe it almoſt always in a paſſive ſtate, as they conſiſt merely in ſhielding the body, and protecting it againſt external agents. Its properties are well ſuited to this office of a general protecting medium. Very large weights are ſupported by ſlender ſtrips of ſkin, and dragging in any direction tears them with great difficulty. Yet this reſiſtance is ſtill much leſs than when the corion has been ſubmitted to the action of the tanning principle. After ſuch preparation it offers the ſtrongeſt connecting medium which we have in the arts: no other tiſſue in the animal economy, except the fibrous, unites in ſo remarkable a degree pliability and reſiſtance.

Haller, who regarded cellular ſubſtance as the principal component part of moſt organs of the human body, and particularly as forming the baſis of membranes, deſcribes the cutis as being made up of this tiſſue in a condenſed form. "Its ſtructure," ſays he, "is on the whole the ſame as that of membranes; *viz.* made of ſhort, intricate, and cloſely-adhering threads and laminæ. Its external ſurface is denſe; the internal is gradually reſolved into the cellular texture, ſo that there are no accurate limits between the two parts. Under maceration it ſwells and becomes looſened, and ſeparates into its component laminæ and fibres, both in man and animals." Elements Phyſiolog. t. v. p. 3.

The *rete mucoſum*, or reticular body of the ſkin, is ſo called from its ſuppoſed perforations by the papillæ and the hairs, and becauſe it appears of a ſoft mucous nature. It was firſt noticed by Malpighi, after whom it is ſometimes named rete Malpighii. The colour of the ſurface of the body ſeems to reſide entirely in this membrane: Riolan ſaid that the cauſe of the black colour in the negro is in the epidermis, and does not go ſo deep as the true ſkin. Malpighi, by ſhewing the diſtinction between the cuticle and rete mucoſum, demonſtrated the true ſeat of the colour of the body. "Ex quo," ſays he, "deduco non incongruam forte nigredinis Æthiopum cauſam: certum enim eſt ipſis cutam albam eſſe ſicuti et cuticulam, unde tota nigredo a ſubjecto mucoſo et reticulari corpore ortum trahit."

The rete mucoſum in the negro is a thin black layer, about as thick as the cuticle itſelf. Putrefaction eaſily detaches it with the cuticle from the cutis; but it can hardly be ſeparated from the former. It diſſolves in water, and communicates a turbid cloud to it, like that produced by the pigmentum nigrum. Mr. Cruikſhank deſcribes it as being "double, and conſiſting of a grey tranſparent membrane, and of a black web, very much reſembling the nigrum pigmentum of the eye." The demonſtration of this reticular body is much leſs eaſy in the white races than in the negro; and indeed very little ſeems to be known concerning its anatomy in the former. "Moſt authors," ſays Bichat, "repreſent the rete mucoſum as a mucous ſtratum interpoſed between the cutis and epidermis, and pierced by a large number of openings for the paſſage of papillæ: but I do not underſtand how this can be demonſtrated on detaching the cuticle, if it be fluid according to the uſual deſcription. I have employed, for diſcovering it, ſeveral means, none of which has ſucceeded. So cloſely does the cuticle adhere to the cutis, that they cannot be ſeparated without injuring one or the other in the recent ſtate. Yet, if we ſucceed in an attempt of this kind, there is no appearance of mucus on the corion. After a longitudinal ſection, particularly in the foot, where the epidermis is very thick, the line of diſtinction between it and the corion is very manifeſt: but nothing eſcapes from between them. When the cuticle has been removed, after boiling the ſkin, nothing remains on either of the ſurfaces. Maceration and putrefaction, but particularly the latter, produce a kind of viſcid covering on the ſkin, very obvious when the epidermis is detached: but this is produced by decompoſition, and nothing of the kind is ſeen under ordinary circumſtances. I believe, from all theſe conſiderations, that there is no ſubſtance depoſited by the veſſels on the ſurface of the cutis, and forming an exterior covering in the ſenſe in which Malpighi has repreſented the matter. I think we ſhould underſtand, by the reticular body, an inter-texture of extremely fine veſſels, the trunks of which, already very minute, after paſſing through the numerous perforations of the corion, are ramified on its ſurface, and contain different kinds of fluids. The exiſtence of this vaſcular net-work is placed out of all doubt by minute injections, which entirely change the colour of the ſkin on the outſide, without altering it much internally. This is the principal ſeat of the various eruptive diſorders, moſt of which are altogether foreign to the corion.

"We may then conceive the reticular body as a general capillary ſyſtem, ſurrounding the cutaneous organ, and forming, with the papillæ, a ſtratum intermediate to the corion and epidermis. In the white part of the human race this ſyſtem contains only white fluids; in the negro they are black, and of various tints in the other varieties of our ſpecies. The enumeration of the different ſhades of this organ, and the conſideration of the cauſes of theſe varieties, belong to the natural hiſtory of man. Hitherto we have very few data concerning this ſubſtance: it does not ſeem to circulate in the part. We ſee that the negro's ſkin is black, and we know very little more. The rete ſometimes adheres to the cutis, but generally to the cuticle, when they are ſeparated after maceration. It is manifeſtly foreign to both, ſince they have the ſame colour in the dark as the white races."

It ſeems really to be a matter of doubt, whether in the white races there be any colouring-matter in the exterior capillary ſyſtem analogous to the black ſubſtance of the negro, or whether the colour of their ſurface ariſe merely from that of the cutis and cuticle. That there is ſome colouring-matter is rendered probable by the ſingular anomaly exhibited in the *albinos*; which ſee. We can demonſtrate in that caſe the abſence of the pigmentum nigrum of the eye, and we ſee clearly the deficiency of colour in the hair. The peculiar dead white of the ſkin is referred, by analogy, to the want of the colouring principle in that organ. There is generally a connection between the colour of the ſkin, hair, and eyes, which is remarkably evinced in this inſtance. A dark complexion is accompanied with black hair and dark eyes; and the light irides, as the blue and grey, occur in individuals with red, flaxen, or other light ſhades of the hair and light ſkin. All theſe circumſtances lead us to conclude that the ſkin, hair, and eyes have their colour dependent on ſome peculiar matter, the tint of which follows a general law in all theſe parts.

Even in the white races certain portions of the ſkin ſometimes exhibit a dark colour. The areola round the nipple becomes black or dark brown in women who are ſomewhat advanced in pregnancy, and affords a very ſure mark that they are pregnant. Haller ſays that he ſaw the ſkin of the pubes in a woman approaching nearly to that of the negro in blackneſs; and Albinus mentions a ſimilar circumſtance in a man.

The colour of the ſkin is tranſmitted to the offspring, and is ſurpriſingly altered by intermarriages of the different races. Where a black and a white individual copulate, the offspring has the middle tint between thoſe of its parents. If the child of a black man ſhould intermarry with a white perſon, and their child with another white individual, and ſo on, the offspring will be white in the fourth generation; or *vice verſâ*. But the detailed conſideration of this ſubject belongs, more properly, to natural hiſtory.

The colour of the cutaneous organ in the white races of the human ſpecies is much modified by accidental circumſtances. Expoſure to the ſun's rays produces various ſhades of a reddiſh-brown colour, which effect is commonly called tanning: this alteration is very rapidly produced by going much on the water, in conſequence of the reflection of the light from its ſurface. That this is the conſequence of the cauſe juſt aſſigned, and that the effect is not produced by heat, is rendered obvious by the difference of colour in the face and hands, and on thoſe parts of the body which are habitually covered: alſo by the brown tint of the face produced by a ſummer's ſun, which offers a remarkable contraſt to that of the forehead, where it is protected by the hat. Our clothes do not prevent the action of heat upon the ſkin, but will intercept the luminous rays. The pale and ſallow tints of the inhabitants of large towns, compared to the florid countenances of country people, ariſe from the ſame cauſe. Men are blanched like plants when ſhut out from the influence of the ſun. Tanning takes place much more quickly in individuals of light complexion, than in thoſe of an oppoſite character. The effect in all caſes is temporary, and goes off when the cauſe no longer acts. It is produced in a greater and more permanent degree in white individuals who move into warm climates: but neither here nor in any other inſtance is it tranſmitted to the offspring. Phyſiologiſts have choſen to repreſent this as a change occurring in the rete mucoſum; on what authority we do not know. The light brown ſpots, called freckles, which occur about the head and neck when expoſed to ſun and air, ſeem to be of the ſame nature with the tanning. The colours impreſſed on the ſkin in the operation of tattowing, reſide in the cutis, and conſequently remain when the cuticle and rete mucoſum have been deſtroyed by maceration. Theſe colours are permanent: they remain through life, and the marks can only be deſtroyed by removing the ſkin which contains them; a circumſtance which is hardly reconcileable to our notions of the conſtant changes of decompoſition and compoſition in all parts of the frame.

Mr. Cruikſhank deſcribes a vaſcular membrane as exiſting between the rete mucoſum and cutis; and apparently it is the ſame as the vaſcular net-work of Bichat. He injected this in the ſkin of perſons who had died of ſmall-pox; and was led to inveſtigate the matter from a converſation with a gentleman who conceived that he had injected veſſels in the rete mucoſum. He macerated in putrid water, during the ſummer, portions of ſmall-pox ſkin, which had been kept for ſome time in ſpirits. "Cuticle and rete mucoſum were already turned down; and upon the eighth or ninth day I found I could now ſeparate a vaſcular membrane from the cutis, in which were alſo ſituated the injected ſmall-pox puſtules. Theſe laſt conſiſted of circles of long-floating villi at the circumference, but of a white uninjected ſubſtance in the centre. This central part Mr. Hunter had previouſly ſaid was a ſlough formed by the irritation of the variolous matter. The ſurface of the ſkin, from whence this membrane was ſeparated, was elegantly porous. The pores now appeared exceedingly more numerous, and this ſurface of the ſkin was ſtill tough and ſhining. I macerated the ſame ſkin for four or five days more, and ſeparated another membrane, more delicate than the former, but alſo vaſcular. The former I eaſily preſerved; the latter, attracted by the inſtrument that ſeparated it, or unable to bear the agitation of the water or ſpirits in which it was ſeparated, conſtantly broke down. But the correſponding ſurface of the ſkin was ſtill tough and ſhining; the pores were now much larger and more diſtinct than before, and convinced me that the appearance was natural, and that the ſkin had ſuſtained no real injury in the proceſs." Experiments on the inſenſible Perſpiration of the Human Body, &c. p. 38.

It has generally been ſtated that the rete mucoſum is not regenerated when it has been deſtroyed in ulcers; and conſequently that the cicatrices of blacks are always white. We believe that this point is not clearly proved.

Whatever opinion we may form concerning the different ſtrata deſcribed above, as intervening between the cuticle and cutis, whether we regard them as diſtinct membranes, or as portions detached by art from the cutis, they are of importance, as containing an extenſive diſtribution of capillary veſſels. Independently of the colouring matter, theſe veſſels ſeem ordinarily to be filled with white fluids: the exhaling pores, which furniſh the matter of perſpiration, ariſe from them, and the ſame vaſcular net-work is the ſeat of eryſipelas, and of all the cutaneous eruptions which do not affect the corion.

"The blood," ſays Bichat, "does not penetrate this capillary ſyſtem in the ordinary ſtate: but numerous cauſes will lead to its being ſuddenly diſtended. Rub the ſkin a little roughly, and it is inſtantly reddened. Irritate it mechanically or chemically, its ſenſibility is immediately awakened, it becomes filled with blood, which could not enter before, and is reddened in a ſurface proportioned to the extent of the irritation. The cheeks exhibit an analogous phenomenon in bluſhing; and all rubefacient membranes ſhew the great tendency of the ſuperficial capillary ſyſtem to admit, under circumſtances of excitation, that blood which it rejects in its natural ſtate. Bliſters, and fire, applied to a degree ſhort of deſtroying the ſurface, act in the ſame way: they cauſe a ſudden ſpecies of eryſipelas, which is followed by an abundant ſerous exhalation under the cuticle.

"Irritation of the ſkin is not the only cauſe which determines an influx of blood into the exterior capillary ſyſtem. Whenever the action of the heart is accelerated, and the motion of the blood conſequently precipitated, there is a tendency to this paſſage, as we ſee clearly after violent exerciſe, or on the acceſs of the hot ſtage in fevers.

"The capillary ſyſtem of the face is more ſubject to this ſudden influx of blood than that of any other part. This is ſeen in the two caſes juſt mentioned, of exerciſe and fever, where the action of the heart is accelerated. In various diſeaſes of internal organs the facial capillaries are ſympathetically affected, and produce redneſs or paleneſs of the countenance; and their diſtention always gives to the face in aſphyxia a livid tint, which is confined to that part. In deaths reſembling aſphyxia, where the circulation becomes embarraſſed in the lungs, and in apoplexy, the head is equally remarkable for its lividity. Three circumſtances may be noticed, in explanation of this great ſuſceptibility of the facial capillary ſyſtem for the admiſſion of blood; 1ſt, the ordinary redneſs of the cheeks ſhews that blood is habitually contained in theſe capillaries in a certain quantity, which is not the caſe in other parts; 2dly, anatomical injections ſhew us that the arteries communicate here more freely with the capillaries; fine injections colour the face much more deeply than other parts; and, 3dly, there is a more acute ſenſibility in the face; a ſlight blow will bring the blood into the cheeks in an inſtant, although it would produce no redneſs in the arm.

"The blood quits the capillaries of the face as quickly as it enters them; the paſſions produce here, almoſt in inſtantaneous ſucceſſion, the lively red of a febrile attack, the deadly paleneſs of ſyncope, or any intermediate ſhades. Thus the face becomes well adapted to ſerve as a kind of ſcene, painted ſucceſſively by the paſſions with numerous ſhades, which are effaced, return, and undergo a thouſand modifications according to the ſtate of the mind.

Let me obſerve further on this ſubject, that the paſſions have a threefold mode of expreſſion in the countenance; 1ſt, by the capillaries which, being altogether involuntary, often betrays what we ſhould be inclined to conceal; 2dly, the muſcular motions, which contract or expand the features to expreſs the ſad or the joyful affections, and thus produce the wrinkles already noticed; and, 3dly, the eye, which, as Buffon obſerves, not only receives ſenſitive impreſſions, but alſo expreſſes mental emotion. The two latter are in ſome degree voluntary; we can feign them, although we cannot deceive with the firſt.

"The tendency of the facial capillaries to become diſtended with blood, diſpoſes them to numerous morbid affections. Eryſipelas frequently attacks this part; variolous puſtules are particularly active here; and ſeveral eruptions occur more frequently in the face than in other ſituations.

"We muſt therefore diſtinguiſh two parts in the capillary ſyſtem exterior to the corion. One contains habitually the colouring matter of the ſkin, which is at reſt, or experiences at leaſt no other motion, than the flow and almoſt inſenſible one of compoſition and decompoſition, and which therefore never exhibits ſuch ſudden changes as we have juſt deſcribed. Though the other fluids are habitually circulated, and are conſtantly eſcaping by tranſpiration; their place is often ſupplied by blood. We know of no communication between theſe; they appear to be abſolutely independent. Some white fluids remain in the latter part at the time of death, as the following experiment will prove. Immerſe a piece of ſkin in boiling water for a ſhort time, and the epidermis will be elevated into numerous ſmall veſicles containing a ſerous fluid."

The *papillæ* of the ſkin are ſmall eminences of its external ſurface, ſuppoſed to perforate the reticular body, and conſequently to be contiguous by their extremities to the epidermis; they differ in form in various ſituations, and are called villi where they are ſmall and fine. Malpighi firſt obſerved in animals, and particularly in the foot of the pig, that the external ſurface of the ſkin is not level, but elevated into certain prominences under the cuticle. This ſtructure does not belong to the whole ſurface of the cutaneous organ, which, although rather unequal in conſequence of ſmall riſings about the hairs, has no regularly arranged parts deſerving to be called papillæ. Thus Ruyſch could find nothing of this kind on the back of the foot, and acknowledges that they are obſcure in other parts, and only to be ſeen after injections; and other anatomiſts have experienced conſiderable difficulty in detecting theſe parts, even with the aſſiſtance of glaſſes.

"Neither," ſays Bichat, "are we to miſtake for papillæ the numerous and very ſenſible tubercles, which make the ſkin of certain ſubjects very rough. Theſe conſiſt of ſmall cellular and vaſcular faſciculi, or of ſebaceous glands found at the openings of the corion under the epidermis, through which the hairs are tranſmitted; elevate the external ſurface, and thus cauſe projections. Maceration for two or three months converts theſe bodies, which always contain a little fat, into the firm, whitiſh, unctuous and ſpermaceti-like ſubſtance always produced from adipous matter by maceration; the ſkin at the ſame time becomes ſoft and pulpy, and is looſened round theſe tubercles, which are clearly ſeen to be continuous with the ſubjacent fat. Theſe prominences are more frequent on the limbs and back than on the front of the trunk; and they are more numerous in the former, on the aſpect of extenſion than of flexion. The abſence of theſe riſings, and a conſequent ſmoothneſs of the outer ſurface of the corion, belong to our notion of a beautiful ſkin; and this character belongs much more to the cutaneous organ of women than of men. The epidermis covering theſe prominences is often detached in ſcales, particularly by any rather ſtrong rubbing; and this contributes ſtill more to the roughneſs and harſhneſs of the ſkin; it might lead us to ſuppoſe that the epidermis forms them, although it is only acceſſary. Where the latter is thick, as in the palms and ſoles, theſe cutaneous tubercles are never ſeen."

The proper papillæ of the ſkin are very viſible in the hands and feet, and may be ſeen when the cuticle has been carefully removed after ſimple maceration for a ſufficient time; but ſtill more plainly when the cutis has been minutely injected previous to the macerating proceſs. We obſerve narrow, longitudinal, and ſlightly prominent lines in the cutis, diſtributed ſpirally at the ends of the fingers and toes. From theſe ridges ariſe very ſmall conical proceſſes like fine threads or hairs, ſlightly inclined towards the nail, ſhorter and more imperfect in the ſmaller toes and fingers; they give a rough villous appearance to the ſurface, which is repreſented in the ſeventh figure of Mr. Cruikſhank's work on the inſenſible perſpiration. They are very diſtinct in the red part of the lips, where they are numerous and long, and produce a villous appearance; Ruyſch has figured them in his eighth Theſaurus. The ſoft and ſpongy ſkin of the glans penis is remarkable for a ſimilar ſtructure, which is well repreſented by Albinus in the Annot. Acad. lib. iii. tab. 4. They are more obtuſe in the female mammæ. The minuteneſs of theſe organs renders it difficult to aſcertain their internal ſtructure ſatisfactorily. They receive numerous blood-veſſels, ſo as to become much more deeply tinged by coloured injections than the ſurrounding ſkin. They receive numerous nerves, and have generally been regarded by anatomiſts in a particular manner as organs of a nervous ſtructure. That a conſiderable ſupply of nerves is beſtowed on thoſe parts of the ſkin which have theſe papillæ is very clear; but, that the minute filaments can be traced into the very prominences, and that they lay aſide their coverings, ſo that the nervous pulp is bare in them, muſt be regarded as inferences from analogy rather than from direct obſervation. The denſity of the corion, and the extreme ſlenderneſs of the nervous threads, are almoſt inſuperable obſtacles to our tracing the nerves into the papillæ.

We can ſcarcely doubt, ſays Haller, that theſe bodies are the organs of touch, when we obſerve them larger, more diſtinct, and receiving a greater ſupply of nerves where this ſenſe exiſts in the moſt acute degree, hardly diſcernible in other ſituations; and particularly calculated by their prominence to be impreſſed by external objects. Perhaps their exiſtence in the ſole of the foot, where they are covered by ſo thick a cuticle, is hardly reconcileable with this opinion.

That the veſſels, which they contain, contribute to the ſeparation of the matter of perſpiration, is ſo conformable to general analogy, that we can eaſily admit it. Mr. Cruikſhank was diſpoſed to regard them as the organs of cutaneous abſorption from their reſemblance to the inteſtinal villi, on which he diſcovered the orifices of the lacteals.

Effect of various Agents on the Dermoid Tiſſue.—We have noticed already, under the head of the rete mucoſum, the action of light upon the living ſkin.

The action of caloric on the living integuments preſents different phenomena, according to the degree in which it is applied. A warm atmoſphere relaxes its tiſſue, increaſes its action, and promotes the evacuation by the exhalants of the reſidual fluid of nutrition and digeſtion. It is contracted and corrugated by cold, and refuſes to admit theſe fluids, which then go off chiefly by urine. The gradual change from one to the other of theſe ſtates does not produce any unpleaſant effect: but ſudden viciſſitudes are not ſo free from danger. The cold produced by the evaporation of the cutaneous exhalation, enables the human ſubject to preſerve his ordinary temperature in air, heated above the degree of boiling water. See the very curious facts on this ſubject detailed in the article HEAT, *Animal*. The interruption of the cutaneous diſcharge on the corrugation produced by cold ſuſpends this evaporation, and thereby prevents the temperature from being lowered beyond the natural ſtandard.

When more conſiderable heat is applied to the ſkin, it produces firſt a ſenſible redneſs, which is followed by veſications. If it be increaſed in degree, the texture of the organ is deſtroyed; it is hardened and curled up, like any other animal tiſſue when burnt; beyond this point it is blackened and converted into a coal. The firſt operation is on the vital powers of the organ, and conſequently can take place only during life: the latter effects are produced on the tiſſue, and may be exhibited in dead ſkin. The latter, when heated, contracts, and then ſwells, exhales a fetid odour, and leaves a denſe charcoal, difficult to incinerate. On diſtillation it yields the ſame products as fibrine. Intenſe cold produces in the firſt place a redneſs of the organ, as in the noſe, ears, fingers, &c. of individuals expoſed in a very cold climate: inflammatory action and mortification enſue. The latter occurs immediately on the application of high temperature, but after ſome interval in the oppoſite caſe.

The air evaporates and carries off habitually the matters ſecreted from the ſkin: and when this effect is not produced, they are accumulated on the ſurface, and render it moiſt. This evaporation is a phyſical phenomenon entirely diſtinct from the vital action of tranſpiration. The latter takes place in a warm bath, as well as in the air; but in the former caſe the fluid is diſſolved by the water. Does free expoſure of the ſkin to air increaſe or diminiſh the amount of its exhalation? The common opinion ſeems to be that the latter effect is produced; the exhaling pores are ſuppoſed to be obſtructed by the impreſſion of cold on the ſkin. Dr. Stark, however, proved by direct experiment in his own perſon, that the body loſt more weight in a given time when naked, than when covered by the ordinary clothing.

Moiſture of the ſkin may be produced in two perfectly diſtinct ways; 1ſt, by increaſed exhalation, which may ariſe from accelerated action of the heart, as in violent exerciſe or fever; from relaxation of the organ by the warmth of the air, or by baths; or from ſympathy, as in conſumption, fear, &c. Under all theſe circumſtances the increaſed diſcharge will keep the ſkin moiſt. 2dly. The ſame effect will be produced by inſufficient diſſolution of the perſpiration when it is produced, as in bed, or in damp weather.

When the air has acceſs to dead ſkin on all ſides, it is dried, and becomes tranſparent, unleſs it ſhould contain blood; it is then firm, but admits of being bent. In this ſtate it yields very little to external agents, does not readily abſorb moiſture, and has no diſagreeable ſmell. Hence ſkins ſimply dried are of great uſe in the arts, and afford ſerviceable and pleaſant coverings; hence, too, probably the great durability of the mummies.

If the ſkin be left on the body, or expoſed in moiſt air, it putrefies, aſſuming ſucceſſively a brown, a greeniſh, and laſtly ſomewhat black colour. It exhales a moſt fetid odour, and becomes ſwollen by the liberation of gas. A fluid mucus appears on its ſurface, from which the epidermis is then ſeparated. When all the fluids are evaporated, a blackiſh ſubſtance remains.

Water removes from the living ſkin thoſe parts of the perſpired matter which are not diſſolved by the air; and the uſe of bathing, which is much neglected in theſe days, muſt be regarded as an efficacious means of preſerving the ſurface free from acrid and irritating matters, and conſequently in a ſtate of health. We cannot ſtate preciſely what action baths have on the living ſkin; we are told indeed that they relax and ſoften, or conſtringe and brace; but no preciſe meaning is attached to theſe vague expreſſions. They ſeem to affect the vital powers of the part, to augment or diminiſh them, but we know of no influence on the tiſſue.

After macerating the ſkin for ſome hours in water, with agitation and preſſure, evaporation of the fluid yields a little gelatine. When macerated longer it becomes ſoftened, and ſenſibly whiter, ſwells a little, and remains for a long time without undergoing any other alteration than a degree of putrefaction, much leſs than what occurs in the muſcular, glandular, and other tiſſues. This putrefaction is more marked on the ſurface in contact with the cuticle, but at the end of two months the ſkin has loſt but little of its conſiſtence; it begins to be reduced into a fetid pulp at the end of three or four months. According to Fourcroy, ſpontaneous decompoſition in water or moiſt earth converts it into a fatty matter, and into ammonia, which compoſe a kind of ſoap. It produces very little froth when boiled. Juſt before ebullition commences, ſo as always to be convex on the ſide covered by the epidermis, and concave on the oppoſite; the fibres are contracted and condenſed at this time, and the contraction is greater on the inner ſurface, where the intervals are the largeſt. At the ſame period ſmall veſications are obſerved. This criſpation of the ſkin renders it denſe, hard, and elaſtic, but reduces its dimenſions. It ſoon acquires a ſemi-tranſparency and yellowiſh colour, like that of the fibrous organs when boiled. The hardneſs which it had acquired at the inſtant of criſpation is now gradually loſt; the ſkin is ſoftened, yields much gelatine to the water in which it is boiled, but inſtead of diminiſhing, is rather increaſed in thickneſs. All appearance of fibres is loſt in this ſtage; a ſemi-tranſparent, gelatinous, and homogeneous maſs remains; ſtill it does not loſe its elaſticity; probably the large quantity of gelatine, which it contains, occaſions it to retain this property. The ſlighteſt motion excites in it a general vibration as in the different animal jellies. By a continuance of the boiling nearly the whole gelatine is diſſolved, conſtituting a viſcid liquor, which by proper evaporation is converted into glue; and a ſmall membranous reſidue only, which is diſſolved with great difficulty, remains; a long time is required to reduce the ſkin to this ſtate. From this ſolubility in water, the cutis of animals is moſtly employed in the manufacture of glue.

Sulphuric, nitric, and muriatic acids act on the ſkin, as on any other animal ſubſtances, but much more ſlowly, particularly on the ſurface covered by the epidermis. The firſt reduces it quickly to a blackiſh pulp; the two others, even in a concentrated ſtate, bring it leſs readily into a pulp: the oxymuriatic acid produces very little effect on it. Nitric acid converts it into oxalic acid and fat, while, at the ſame time, azotic gas and pruſſic acid are emitted. Acids do not act in this way during life: they never produce this pulpy ſtate of the organ. A piece of cauſtic, enveloped in a portion of ſkin, is reduced to a yellowiſh-red thick fluid in the courſe of a day: the ſkin is criſped and contracted, but not penetrated; its tiſſue does not even appear injured on the ſurface. Alkalies have different effects, according to circumſtances, in the living ſtate; they deſtroy ſome granulations much more readily than others. An alkaline lixivium, applied to the ſurface of the body, cauſes an unctuous and ſlippery feel, as its combination with the unctuous matter produces a ſoap. Concentrated alkalies diſſolve the dead ſkin, converting it into oil and ammonia.

"The cutis," ſays Dr. Thomſon, "appears to be a peculiar modification of gelatine enabled to reſiſt the action of water, partly by the compactneſs of its texture, and partly by the viſcidity of the gelatine, of which it is formed; for thoſe ſkins which diſſolve the moſt readily in boiling water, afford the worſt glue. Mr. Hatchett has obſerved that the viſcidity of the gelatine obtained from ſkins is nearly inverſely as their flexibility, the ſuppleſt hides always yielding the weakeſt glue; but this glue is very ſoon obtained from them by hot water." Syſtem of Chemiſtry, v. 5. p. 575.

The production of leather, by the action of the tanning principle of vegetables upon the ſkin, is a ſubject of ſuch importance, that it would be uſeleſs for us to enter on it here: it will be conſidered ſeparately in the articles of the dictionary relating to tanning: further information on the chemical properties of the ſkin may alſo be derived under the heads GELATIN, GLUE, &c.

Very little is known of the chemical conſtitution of the rete mucoſum. Oxymuriatic acid deprives it of the black colour, and renders it yellow in the negro. Beddoes ſtates that immerſion for ſome time in water, impregnated with that acid, will diſcharge the colour in the living ſubject. (On Factitious Airs, p. 45.) Fourcroy mentions that the foot of a negro, after a ſimilar expoſure, nearly loſt its colour, but that the original black hue returned in a few days. Syſt. des Connoiſſ. Chimiques, t. ix. p. 259.

Common Parts belonging to the Tiſſue of the Dermoid Syſtem.—The ſkin contains a large proportion of cellular ſubſtance. Numerous prolongations of the ſubcutaneous cellular ſtratum penetrate the contiguous areolæ of the corion, then paſs into the more exterior ones, and end at the numerous pores which tranſmit the veſſels, nerves, and hairs. Thus, if the cellular tiſſue could be completely ſeparated, the cutaneous organ would repreſent a piece of ſponge, being perforated in every direction. According to Bichat, boils perform this diſſection, deſtroy the cellular organ, and leave the ſkin in this cribriform ſtate. He adds, that the corion itſelf is not the ſeat of any acute affection: that all diſeaſes of this nature either affect its ſurface, or the cellular tiſſue of its areolæ. But it may be altered by chronic diſeaſes; and is manifeſtly diſorganized in elephantiaſis.

In anaſarca of long continuance the ſubcutaneous ſeroſity gradually penetrates the cellular ſubſtance of the dermoid areolæ, ſeparates its fibres, and ſometimes arrives even at the epidermis, which it burſts; through theſe openings it eſcapes.

Probably, ſays Bichat, the cellular tiſſue does not extend ſo far as the external ſurface, under the epidermis: for when that covering is removed, no granulations are formed, although theſe are always produced whenever cellular tiſſue is expoſed.

The arteries, running in the ſubcutaneous cellular ſubſtance, furniſh an infinite number of ſmall branches, which enter the areolæ of the ſkin with the cellular prolongations, anaſtomoſe at every point in the areolæ of the organ, and penetrate at laſt through the pores of the exernal ſurface to produce the capillary net-work already deſcribed, which, in the ordinary ſtate, contains very little red blood. In this paſſage, through the areolæ of the ſkin, very few branches ſeem to terminate on the fibres of the corion itſelf.

After penetrating the ſkin in the oppoſite direction, the veins opens into the large ſubcutaneous trunks, which in many parts may be ſo clearly ſeen through the integuments. The venous ramifications of the areolæ are nearly inſenſible in the natural ſtate, but are conſiderably dilated over cancerous tumours, ſo that the ſkin is marked by numerous blueiſh ſerpentine lines. All gradual extenſions of the cutaneous organ, as in aneuriſms, pregnancy, dropſy, &c. are attended with the ſame phenomenon, which is never exhibited in acute caſes.

Numerous and conſiderable branches of nerves form a kind of ſubcutaneous nervous ſyſtem, producing the filaments which enter the ſkin. They communicate with each other in traverſing the areolæ of the organ, and probably terminate on the papillæ. In the hand, where theſe prominences are very numerous and clearly marked, there are more ſubcutaneous nerves, in proportion to the ſurface, than in any other part.

A great number of abſorbing veſſels is found under the ſkin; inſomuch, indeed, that this is the moſt favourable ſituation for inveſtigating them. The veins are ſurrounded by them, and ſeveral faſciculi are obſerved in the intervals of theſe veſſels; ſo that we may repreſent the ſkin and aponeuroſes as being ſeparated, in the limbs, by a continuous ſtratum of theſe veſſels. We muſt refer the origin of many of them to the corion, from the areolæ of which they carry into the blood the fat and cellular lymph, as well as the nutritive matter of its fibres. But is there, moreover, a particular order of branches opening on the epidemis, for the purpoſe of abſorbing ſubſtances from the ſurface of the body under certain circumſtances? Anatomical inveſtigations do not enable us to decide this queſtion directly: the abſorbing pores cannot be demonſtrated: we muſt therefore inquire whether the phenomena of the cutaneous functions indicate their exiſtence. We may obſerve, previouſly, that the ſuperficial abſorbents are very numerous, and ſeem to be in greater number than would be required for abſorbing the contents of the cellular ſubſtance.

It had long been received as an eſtabliſhed truth, that the ſkin is an inhaling or abſorbing, as well as an exhaling organ; that though the loſs by perſpiration commonly greatly exceeds what the ſyſtem gains by abſorption, yet ſometimes, according to the varying circumſtances of external relations and conditions of the body itſelf, the inhalation balanced, and even ſurpaſſed the exhalation. Of late this doctrine of inhalation has been called in queſtion, and, in the opinion of many, has been completely overthrown.

The moſt direct argument in favour of abſorption from the ſkin, is the action of various ſubſtances upon the body, when applied to this organ. This is ſhewn in a particularly clear view in the inſtances of opium and mercury. Dr. Currie (Medical Reports, chap. 19.) conſiders, that in all ſuch caſes the article abſorbed is forced through the epidermis by mechanical preſſure; or that the epidermis has been previouſly deſtroyed by injury or diſeaſe; or if ſound, that the article applied to it is of an acrid nature, which firſt irritates and erodes this tegument; and then coming into contact with the mouths of the lymphatics under it, is of courſe abſorbed. This explanation is quite unſatisfactory. The firm adheſion of the cuticle and cutis is well known: on the ſuppoſition juſt mentioned they ought to be ſeparated, which is not the fact, we ought to ſee the ointment under the cuticle, which is equally untrue, and the ointment ſhould penetrate equally in the dead ſubject, which is not the caſe. However, the action of mercurial fumigations, where no friction is employed, affords a caſe of abſorption from the ſurface of the ſound cuticle, which cannot be denied.

On the ſame ſide of the queſtion, it has been aſſerted, that water is taken up by the ſkin in various caſes. Many inſtances have been known of perſons at ſea, with no freſh water, having their thirſt much allayed by wetting their cloths with the ſalt water. Haller affirms, too, on the authority of Deſault, that the body acquires an increaſe of weight in the warm bath: "denique vapor aquæ calidæ in manum reſorbetur, et homini in balneo conſtituto cutis tumet et rubet, corpus pondere augetur, ſitis ſedatur, et omnia ſigna eduntur aquæ reſorbtæ et ſanguini admiſtæ." t. v. p. 88. Experiments have ſince been made with every neceſſary care, which ſeem to contradict this poſition, and to prove that the body acquires no additional weight in the warm bath. Seguin, from a great many experiments of this deſcription, concludes that there is no inhalation, becauſe the body, ſo far from gaining, always loſt ſome part of its weight during immerſion, although much leſs than in the air in equal times. Thus, in a bath heated from 10° to 12° of Reaumur, the loſs of weight was to that ſuſtained during the ſame time in air as 6.5 to 17; at the temperatures from 15° to 18°, as 7.5 to 21.7; and from 26° to 28°, as 13 to 23. La Medecine eclaircé par les Sciences Phyſiques, tom. iii.

In other experiments, again, as in thoſe of Drs. Gerard and Currie, there was no increaſe of weight; but neither was the body in general obſerved to have ſuffered any loſs during immerſion in the warm bath. "When I was at Buxton," ſays Dr. Currie, "in 1788, I made an experiment on the effects of bathing on the weight of my body, and after half an hour's immerſion, I found it rather diminiſhed than increaſed. This experiment had, I believe, been made before by Dr. Pearſon with the ſame reſult; it has ſince been repeated with great care, and it is aſcertained, as a fact, that no increaſe in the weight of the body is produced by immerſion in water at the temperature of 82°. In the year 1790, I had a patient in diabetes, whoſe cuticle, as is uſual in that diſeaſe, was in a morbid ſtate; and being deſirous of trying how far the inordinate action of the kidnies might be affected by a gentle ſtimulus applied to the ſkin, I immerſed him in a bath of the temperature of 96°, weighing him before and after immerſion. There was no ſenſible variation in the weight. This experiment has ſince been made by Dr. Gerard in another caſe of diabetes, an account of which is given in the publication of Dr. Rollo; and as it was repeated a great number of times with the utmoſt care and accuracy, it may be conſidered as eſtabliſhed, that immerſion in the warm bath in diabetes produces no increaſe in weight. I have made five different experiments of the ſame kind on myſelf, varying the heat of the bath from 87° to 95°, but never in any inſtance found my weight augmented." (Medical Reports, vol. i. p. 302.) The doctor then details a caſe of ſtrictured œſophagus, where the patient gradually waſted, and ultimately died of inanition, although he was immerſed daily in a tepid milk and water bath.

We may obſerve, concerning the facts juſt quoted, that they by no means warrant a deciſive negative inference. We have every reaſon to ſuppoſe that the action of the ſkin goes not uninterruptedly in the bath, and that the pulmonary exhalation proceeds as uſual. Yet the weight either continued unchanged, or, if any loſs was obſerved, this was conſtantly leſs, much leſs, than is experienced during the ſame interval in air: hence we may argue, that there muſt have been abſorption. Dr. Currie's caſe of ſtrictured œſophagus merits further conſideration: no experiment could be more unfavourable for an opponent of cutaneous abſorption. The patient, it is true, gained no weight while in the warm bath, but the loſs continually going on in the air, was, as in other trials, ſuſpended during the immerſions. "It is worthy of obſervation, that there was neither increaſe nor decreaſe of weight in the bath; yet Mr. M. was at this time waſting twenty ounces in 24 hours, and conſequently, if there was no abſorption in the bath, it might be ſuppoſed that he would have loſt five-ſixths of an ounce during the hour of immerſion. It is the more remarkable that there was no decreaſe, becauſe in the bath the ſkin always ſoftened, and the forehead became covered with a gentle moiſture." Beſides, "he always expreſſed great comfort from the bath, with abatement of thirſt,"

thirſt,” and “ ſubſequent to the daily uſe of it, the urine flowed more plentifully, and became leſs pungent.” An obſervation preciſely ſimilar is made by Mr. Cruikſhank: “ a patient of mine, with a ſtricture of the œſophagus, received nothing, either ſolid or liquid, into the ſtomach for two months; he was exceedingly thirſty, and complained of making no water. I ordered him the warm bath for an hour, evening and morning, for a month; his thirſt vaniſhed, and he made water in the ſame manner as when he uſed to drink by the mouth.” Anatomy of the Abſorbing Veſſels, p. 101.

Dr. Currie ſtates further, concerning his patient, that the diſcharge by urine alone exceeded much in weight the waſte of his whole body; and it cannot be doubted, he adds, that the diſcharge by ſtool and perſpiration exceeded the weight of the clyſters. Thus it appears that the egeſta exceeded the ingeſta in a proportion much greater than the waſte of the body will explain.” That cutaneous abſorption affords the only adequate ſolution of this phenomenon is an irreſiſtible concluſion. Still, however, this is denied. When forced to confeſs that there are caſes where the egeſta exceed the ingeſta, and which can only be accounted for by abſorption, the opponents of the cutaneous inhalation deny this function to the ſkin, and beſtow it moſt gratuitouſly on the lungs.

Many other examples might be cited, in which the body evidently acquired weight from ſome other quarter than by the food or drink. Haller has many ſuch inſtances. Rye and Linings gained ſeveral ounces by expoſure in a moiſt atmoſphere: and Fontana experienced a ſimilar occurrence.

Some facts, which oppoſe the notion of inhalation by the ſurface of the ſkin, have been obſerved in the applications of medicated ſubſtances to the body. Seguin made numerous experiments of this kind, with ſolutions of muriate of mercury on ſyphilitic patients: we are informed, that in caſes where the epidermis was perfectly ſound, neither the known effects of mercury on the body, nor any amelioration of the venereal ſymptoms, was ever obſerved. He alſo immerſed his own arm in a ſolution of two drachms of the mercurial muriate in ten pounds of water. At the temperature of 10° and 28° of Reaumur, no part of the ſalt was miſſing at the end of the experiment; but when the bath was at 18° of the ſame ſcale, there was a loſs of one or two grains of the muriate in the hour, though the quantity of fluid was not diminiſhed. It appears to us that the experiments on the whole ſhew that the muriate of mercury was not abſorbed; we can hardly admit that two grains were taken up as ſtated in this account. The entrance of ſo large a quantity of this very active preparation into the ſyſtem, muſt have been attended with very unpleaſant effects on the ſubject of the experiment, which do not ſeem to have occurred.

The effects produced on the odorous properties of the urine, by expoſure of the body to oil of turpentine, are well known. By inhaling the vapour of this fluid, the violet ſmell is imparted to the urine very ſpeedily: even a ſingle full inſpiration is ſufficient to produce the effect. Walking in a room where it has been ſpilled will operate in the ſame way. It has been proved by experiment that the lungs are the organs by which the abſorption takes place, and that the fluid is not taken up by the ſkin. Dr. Rouſſeau, of Philadelphia, expoſed his body freely to the turpentine vapour, breathing through a pipe, which communicated with the external air, and had no connection with the air of the room. No effect was produced on the urine. He immerſed his arm in ſpirit of turpentine for two hours, luting the veſſel containing it to the arm, ſo that no vapour could eſcape; no change was perceptible in the properties of the urine. He ſmeared his body all over ſeveral times with the ſpirits of turpentine, guarding againſt the inhalation of the vapour of the lungs, by breathing the external air through a tube. He continued this for ſome time, until the ſurface was irritated, and the pulſe quickened; the reſult was the ſame. Theſe experiments were frequently repeated, and with the ſame reſult, whether the ſpirit of turpentine was employed, or camphor, garlic, or muſk. Currie's Med. Rep. v. 1. chap. 19.

The exhalant veſſels of the ſkin ariſe in the exterior capillary ſyſtem, which ſurrounds the corion, and which affords the point of termination of the cutaneous arteries. They draw from this ſource the fluid which they pour out on the epidermis. We are entirely ignorant of their form, length, courſe and direction: but the phenomena of the cutaneous diſcharge, and of injections prove their exiſtence. They do not ſeem to be equally abundant in all parts: in the face and cheſt they are numerous, ſo that we ſweat eaſily in thoſe parts; the number is ſmaller in the back and limbs. Sweat is very ſeldom obſerved in the palms and ſoles: but there is great variety in theſe reſpects in different individuals.

It appears from experiments, that a conſiderable diſcharge takes place from the ſkin habitually, although not in a form cognizable by our ſenſes. This is called inſenſible perſpiration, or tranſpiration. Under particular circumſtances, the cutaneous diſcharge conſiſts of fluids poſſeſſing very ſenſible properties: this is called ſweat. The epithet inſenſible is applied to the former, to diſtinguiſh it from the ſweat, but under certain circumſtances it may be rendered obvious to the ſenſes. It has been often aſſerted that a vapour may be obſerved to ariſe from the body, and may be recognized by its ſhadow againſt a white wall in the ſummer. This is obſerved more readily in a denſe atmoſphere. Haller ſaw a kind of cloud or ſmoke ariſing from the face, hands, and indeed every part of the naked body in the ſubterraneous excavations of Clauſthal and Rammelſberg. A ſtill more obvious demonſtration of the tranſpiration is yielded by holding a finely poliſhed metallic ſurface near the ſkin; the watery vapour is condenſed by the metal, and clouds it. Under ordinary circumſtances, the whole diſcharge is evaporated as it is produced, and paſſes off in this inviſible form. As all bodies abſorb heat in changing from a fluid to a gaſeous form, this evaporation muſt have a very powerful effect in regulating the temperature of the animal frame. When the nature of our clothing confines the perſpiration, and prevents its evaporation, an unpleaſant feeling of heat is produced; this is particularly obſerved when the body is covered with oiled ſilk. On the other hand, expoſure of the ſkin in a naked ſtate, particularly in the wind, has a very rapid and powerful cooling effect. The importance of this function in regulating our heat did not eſcape the notice of that ſagacious obſerver Benj. Franklin: “ during the hot Sunday at Philadelphia, ſays he, in June 1750, when the thermometer was up at 100° in the ſhade, I ſat in my chamber without exerciſe, only reading and writing, with no other clothes on than a ſhirt, and pair of long linen drawers, the windows all open, and a briſk wind blowing through the houſe. The ſweat ran off the backs of my hands, and my ſhirt was often ſo wet as to induce me to call for dry ones to put on. My body, however, never grew ſo hot as the air, or as the inanimate bodies immerſed in the air.” (Letters and Papers, p. 365.) It does not appear that Franklin actually meaſured his heat; but he makes the inference of his comparative coolneſs from remembering that all the bodies about him, even the ſhirt out of his drawer, felt warm to the touch; and he concludes that he was kept cool “ by the continued ſweating, and by the evaporation of that ſweat.”

Probably ſweat is only an increaſed quantity of the ſame kind of fluid with that of the tranſpiration : very ſmall particles of fluid are obſerved on the ſkin, and they unite into larger and larger drops. Heat is the moſt common cauſe of ſweating, as it is a very powerful means of exciting the action of the heart, on which this phenomenon depends in many caſes : hence warm air and the warm bath are powerful cauſes. Strong bodily exertion, and warm food, by ſtimulating the vaſcular ſyſtem, produce the ſame effect. Fear, and other affections of the mind, fainting, and various morbid ſtates of the frame, alſo produce ſweating. We cannot name any particular degree of heat at which ſweating is certainly produced : and the pulſe is often very greatly accelerated in diſeaſe without this conſequence. Sometimes a particular part of the body only ſweats : ſometimes one ſide, as Haller has noticed in his own perſon.

Bichat enquires whether the nerves have any influence on the cutaneous diſcharge. He obſerves, that in palſied patients ſweat takes place on the diſeaſed as well as on the ſound ſide. "I lately," ſays he, "attended at the Hôtel Dieu a patient, in whom the left ſide of the body was rendered perfectly paralytic, in conſequence of an apoplectic attack : yet he ſweated only on this ſide. Examples of the oppoſite phenomenon are adduced ; but they cannot invalidate the common obſervation that the diſcharge is equal on both ſides. Is it not well known, that when the nervous action is entirely annihilated in a paralytic limb, bliſters affect it in the uſual manner ? Do convulſions, in which the nervous action is increaſed, augment the cutaneous exhalation ? Have the ſtates of acute ſenſibility, where there is in the cutaneous nerves ſo great a ſuſceptibility of impreſſions, any known influence on perſpiration ? Let us then confeſs, that in cutaneous exhalation, as well as in ſecretion, we are entirely ignorant of the nature of the nervous influence, if any ſuch exiſt."

The diſcharges by the ſkin and the kidney ſeem to be regarded by phyſiologiſts as the principal means by which the reſiduary matter of nutrition and digeſtion is expelled from the body : and they have attempted to ſhew the ratio which theſe bear to each other, to the pulmonary exhalation, and to the feces. We have not derived much information from theſe labours, which merely prove, in a general manner, that the diſcharge is effected through the internal organs in cold climates and ſeaſons, and through the ſkin under oppoſite circumſtances. In this reſpect, the kidney and the ſkin are always in oppoſite ſtates in relation to each other : in winter the urine is much loaded with ſubſtances, and in ſummer the perſpiration has a ſalt taſte and other peculiar characters, ariſing from matters which it does not contain in the former ſeaſon. Every individual muſt have obſerved in his own perſon that while he ſweats freely no urine is collected in the bladder ; and, that when the cutaneous diſcharge is interrupted, the ſecretion of the kidney goes on very actively.

We do not know much about the pulmonary exhalation, either as to its quantity, its nature, or its relations to the cutaneous diſcharge : but that the two organs very powerfully influence each other, is rendered very obvious by the phenomena of diſeaſe. The effect of expoſure to cold and moiſture in exciting pulmonary affections, and the diſpoſition to ſuch diſorders in the winter, when the cutaneous exhalants are leſs active, are well known.

We often have occaſion to obſerve a manifeſt connection between the perſpiration and the alvine diſcharges.

When the extent of the exhaling organ, the innumerable tubes by which it is penetrated, the quickneſs with which we can even ſee the perſpiration produced, are regarded, we ſhall expect to find that the quantity of the diſcharge is very conſiderable. Although it was known to the ancients, who had noticed its influence on the health, and introduced it into their pathology, we find little detailed information concerning this function before the ſeventeenth century, about the beginning of which it became the ſubject of the moſt patient reſearch, and of the moſt extenſive experiments perhaps ever undertaken. Sanctorius, a Venetian phyſician, dedicated thirty years to his experiments, which conſiſted chiefly in weighing whatever he ate and drank, as well as what he diſcharged by urine and ſtool. From him the inſenſible perſpiration has ſometimes received the epithet of Sanctorian. His example was followed by ſeveral perſons in different countries ; by Dodart in France ; by Keil, Robinſon, Rye, and Home in this country ; and by Linings, in South Carolina. Even our gay monarch, Charles II. amuſed himſelf with ſome experiments on this ſubject. Something muſt be taken from the numbers expreſſing the quantity of perſpiration, on account of the pulmonary exhalation, the mucus of the air paſſages and noſe, and ſpitting. For, in the experiments now alluded to, all the difference between the ingeſta and the egeſta is ſet down as loſs by inſenſible inſpiration.

In the experiments of Home, in Scotland, the food amounted to 4 lb. 3 oz. ; the feces to $3\frac{1}{2}$ oz. ; the urine to $2\frac{1}{2}$ lb., or $3\frac{1}{2}$ lb. ; the perſpiration, in the courſe of an hour, varied from two-thirds of an ounce to 4 oz., and even ſix under expoſure in the ſun. In the twelve hours of night, the perſpiration varied from 12 to 18 oz. ; and in $23\frac{1}{2}$ hours the diſcharge amounted to 3 lb. $3\frac{1}{2}$ oz. ; and on another occaſion, to 2 lb. $6\frac{1}{2}$ oz.

Rye, who lived at Cork, in Ireland, found the urine in the winter ſeaſon to amount in one day to $42\frac{7}{10}$ oz. ; the perſpiration to 53 oz. in ſpring, the urine wae 40 oz. ; the perſpiration 60 : in ſummer the numbers were 37 and 63. The average daily quantity of urine, therefore, was rather leſs than 40 oz., and that of the perſpiration $56\frac{1}{2}$ oz. The average daily amount of the feces was $4\frac{1}{2}$ oz. ; that of the food 96 oz. The large quantity of perſpiration in the winter is chiefly made up of what is produced during the night.

Keil found the medium quantity of perſpiration to be 31 oz. ; of urine 38 ; of feces 5 ; food 78.

Robinſon allows that the urine is diminiſhed, and the perſpiration increaſed in a very ſenſible manner in the ſummer, ſo that the average number of ounces of the former is in ſummer 27, in winter above 30. In the ſummer months the perſpiration and urine are as 5 and 3, in the winter as 2 and 3 ; in April, May, October, November, and December, they are nearly equal. In a young perſon he eſtimates the ratio of the perſpiration to the urine as 1340 to 1000 ; in an old one as 967 to 1000. He makes the average quantity of food 86 oz., and 58 when he was old ; the urine 35 and 28 ; the perſpiration 46 and $27\frac{1}{2}$; the feces $5\frac{1}{2}$ and $3\frac{1}{2}$. Thus the food and all the excretions are diminiſhed as age advances.

Hartman, in Germany, found the food to be 8 oz. ; the urine 28 ; feces 6 or 7 ; and perſpiration 45 or 46.

Dodart, in France, found that the perſpiration was to the feces as 7 to 1. He eſtimates the diſcharge in ſummer at 40 oz. 3 dr. 26 gr. ; in winter at 26 oz. 46 gr.

Sanctorius, in the warm and humid air of Venice, took 8 lb. of food ; the perſpiration amounted to 5 lb. ; the feces to 4 oz. ; and the urine in the night to 16 oz. ; in the twenty-four hours to 44 oz.

Linings has given us very accurate accounts of his experiments, which were performed in South Carolina. From his labours, as well as from thoſe of Robinſon, in Ireland, it appears that the perſpiration is moſt abundant in the warm months, and the urine in the cold: the former was in greater quantity during five months, and the latter during ſeven. The largeſt proportion of urine was 143 oz. which occurred in the month of December; and of the perſpiration 130 oz. in September. The average daily amount of the food, on a mean of experiments continued for a year, was 27,18 oz.; of the drink 102,17; of the urine 64,84; of the perſpiration 60,10; of the feces 4,35. The ingeſta were to the urine, throughout the whole year, as 2,02 to 1: but at many particular times they were as 3 to 2; their ratio to the perſpiration as 2,18 to 1; to the fecal diſcharge as 30,13 to 1; and the perſpiration of the whole year to the urine as 1 to 1,08. Theſe experiments differ from thoſe of Sanctorius and of Rye, in ſhewing that the urine exceeds the perſpiration even in a hot climate.

It appears doubtful, ſays Haller, on comparing together the reſults of the trials made by individuals of different ages in various climates and ſeaſons, whether the diſcharge by the ſkin exceeds that by the urine. On ſuch a compariſon we muſt ſet down the cutaneous exhalation much below the quantity aſſigned by Sanctorius, as it did not exceed 60 oz. in a very hot climate, and in colder countries was 56, 46, or even 30 oz.

It will be readily perceived, as we have already obſerved, that theſe calculations do not give the meaſure of the perſpiration alone, but of the cutaneous and pulmonary diſcharges together. To ſeparate theſe, and to determine the quantity of each, ſtill remained an important problem, the ſolution of which has been attempted only of late years.

Mr. Cruikſhank introduced his hand into a glaſs jar, and tied a bladder, fixed to the mouth of the jar, round his wriſt. In leſs than a minute the inſide of the bottle was rendered dim, as if it had been held over the ſteam of warm water: ſmall drops appeared in leſs than ten minutes, and a teaſpoonful of tranſparent and perfectly inſipid fluid, weighing 30 gr., was collected in an hour. Aſſuming that the hand is to the whole body as 1 to 60, and that the whole ſurface perſpires equally, the exhalation at this rate would be 7 lb. 6 oz. in 24 hours. When the experiment was repeated after taking exerciſe, 48 gr. were collected in an hour, which is at the rate of 12 lb. in 24 hours. By breathing into a bottle for an hour, this gentleman collected 124 gr. of inſipid tranſparent fluid: the produce in 24 hours at this rate would be 6 oz. 1 dr. 36 gr. If this be added to the former ſtatement of the cutaneous exhalation, the ſum will be 8 lb. 1 dr. 36 gr.; and the evaporation from the lungs will be little more than $\frac{1}{17}$th of the whole. Bichat ſays that he collected 2 oz. of fluid by breathing for an hour into a veſſel. Anat. Gener. t. 2, p. 701.

Mr. Abernethy collected from his hand and wriſt, incloſed in a glaſs jar for ſix hours, about 3 dr. of fluid. He eſtimated the ſurface from which this was collected at $\frac{1}{25}$th of the whole body: hence, if the perſpiration be equal at all times and in all parts, the produce in one day would be about 2½ lb. This reſult is ſo different from that of Mr. Cruikſhank, that there muſt be ſome ſignal error in the data on one ſide or the other.

The method adopted by Lavoiſier and Seguin ſeems calculated to afford reſults more worthy of our confidence. The whole body was incloſed in a ſilk bag, varniſhed with elaſtic gum, impenetrable by air or moiſture, having a ſmall opening carefully cemented round the mouth through which the perſon might breathe; ſo that whatever came from the lungs eſcaped, while the whole of the cutaneous diſcharge was confined within the bag. By weighing the body, therefore, before putting on this dreſs, and immediately after leaving it, the total loſs by the pulmonary and cutaneous diſcharges was aſcertained. The amount of the loſs by the lungs was known by weighing the ſubject of experiment juſt before he put on the dreſs, and again immediately before he removed it. When the latter quantity was ſubtracted from the total loſs, the remainder gave the value of the cutaneous diſcharge. From repeated trials performed in this manner, Seguin and Lavoiſier found the mean loſs, by the cutaneous and pulmonary exhalations, to be about 18 gr. in the minute, or 2 lb. 13 oz. in 24 hours. The pulmonary diſcharge amounted to 15 oz.; ſo that there remains 1 lb. 14 oz. as the mean quantity of daily perſpiration.

The greateſt quantity of matter perſpired in a minute was 26,25 gr. troy; and the minimum 9 gr. The quantity perſpired is increaſed by drink, but not by ſolid food. Perſpiration is at its minimum during meals, and immediately after: it reaches its maximum during digeſtion. Mémoires de l'Acad. des Sciences, 1790; or in Fourcroy, Syſt. des Connoiſſ. Chimiques, ſect. 8, ord. 3.

Our next object of inquiry is into the compoſition and properties of the cutaneous exhalation. As it eſcapes from the ſurface inſenſibly, there is a difficulty in collecting it in ſufficient quantity for examination: hence its nature and compoſition are very imperfectly known. Liſter, who collected it by placing his hand in a glaſs, found it to be water with a ſaltiſh or urinous taſte.

The fluid collected by Mr. Cruikſhank appeared to poſſeſs all the properties of pure water. When Mr. Abernethy had procured 3 dr. of fluid, he evaporated one-half: there remained on the glaſs a ſmall reſiduum, which had a very ſlight taſte of ſalt. The other half was ſuffered to ſtand many days, in which time no change appeared. It did not alter the colour of vegetable blue; no coagulation or precipitation of animal matter was produced by muriatic acid, neither was any change cauſed by the addition of pure alkali. It appeared, therefore, to Mr. Abernethy, that the water of perſpiration contains little of any thing, except a very ſmall portion of ſalt.

We cannot reaſonably doubt that the greater part of the matter of perſpiration is water; but it certainly contains other matters, of which the nature is not well aſcertained. Its ſenſible properties are often very perceptible: it cauſes the peculiar odour of the body, which is very remarkable in particular individuals, and poſſeſſes peculiar characters in whole races of mankind. Its ſmell is often ſour; and it is ſaid, under ſuch circumſtances, to change the vegetable blue colours to red. Berthollet thought he had detected the preſence of the phoſphoric acid; he obſerved that a blue paper, applied to a part labouring under a gouty paroxyſm, became red; but Fourcroy remarks, that if this acid were conſtantly ſecreted, it muſt accumulate on the ſkin, as it is too fixed to be volatilized with the aqueous vapour of perſpiration.

From the ſtrong odour of the perſpiration when profuſe, and from the tinge which it communicates to linen, there is reaſon to ſuppoſe that it contains a particular animal matter. In the perſpiration of the horſe, an animal ſubſtance of the nature of urea has been detected by Fourcroy and Vauquelin, who have alſo diſcovered that the phoſphate of lime is left in conſiderable quantity by the evaporation of the perſpired matter on the ſkin of the ſame animal. It ſeems to cryſtallize on the ſurface, and forms the branny matter detached by friction of the ſurface. The above-mentioned chemiſts obſerve that the urine of this animal contains no calcareous phoſphate.

Mr. Cruikſhank's experiments prove clearly that there is an oily matter ſecreted by the ſkin: indeed the familiar appearance of the repulſion of water, ſo as to cauſe it to run into globules, ſufficiently evinces the fact. Mr. Cruikſhank wore the ſame veſt of fleecy hoſiery night and day during the hotteſt part of the ſummer. At the end of this time he always found an oily ſubſtance accumulated in conſiderable maſſes on the nap of the inner ſurface of the veſt, in the form of black tears. When rubbed on paper, it makes it tranſparent, and hardens on it like greaſe. It burns with a white flame, leaving behind a charry reſiduum.

Beſides the condenſable vapour which is exhaled from the ſkin, it has been aſſerted that gaſeous fluids are alſo ſeparated. Many philoſophers have laboured on this ſubject, but the reſults of their experiments are ſo contradictory, that we cannot deduce from them any very ſatisfactory concluſion.

The count De Milly ſeems to have been the firſt who called the attention of philoſophers to this ſubject. He had often remarked the accumulation of ſmall air-bubbles on the ſurface of his body, when immerſed in the warm bath. At length, by means of a funnel and inverted glaſs jar he collected, in a few hours, half a French pint of the gas, which was examined by Lavoiſier. It was incapable of ſupporting combuſtion, produced a precipitation in lime water, and ſuffered no change from the admixture of nitrous gas. Acad. Roy. des Sciences de Berlin, 1777.

Mr. Cruikſhank found that a lighted taper, introduced into a bottle in which his hand or foot had been confined for ſome time, burned dimly; and lime water agitated in it was rendered turbid.

Ingenhouz could not procure the air from the ſkin in the warm bath in ſuch quantity as the Count de Milly did. What he collected ſeemed to be azotic gas. Experiences ſur les Vegetaux, t. 1.

Prieſtley denies that any gas is perſpired by the ſkin. He repeated the experiments of Ingenhouz, and never could obſerve the appearance of gas ariſing from the body when he employed boiled rain water, from which the air had been completely expelled, and detached the adhering bubbles from his arm. He obſerves that the air obtained by Ingenhouz "was juſt that mixture of fixed air and partially phlogiſticated air, that pump-water, which he recommends for the purpoſe, generally abounds with." Experiments and Obſervations, vol. v. p. 103.

Fontana arrived at the ſame concluſion from his reſearches.

Such alſo was the reſult of Mr Jurine's experience, who, after remaining in the bath at different temperatures from 18° to 30° of Reaumur for hours together, never could procure a ſingle bubble of air from his ſkin. He obtained the ſame reſult from obſervations on ſeveral individuals in water of various temperatures. Hiſtoire de la Societé Royale de Medecine, tom. 10.

Mr. Cruikſhank's experiments ſeemed to prove that air, which has been confined for ſome time in contact with the ſkin, becomes changed; though Dr. Prieſtley maintained that the perſpirable matter has no ſuch effect on the air, but leaves it as wholeſome as ever.

A very extenſive ſet of experiments performed by Mr. Jurine, of Geneva, and publiſhed in the volume already quoted of the Memoirs of the Royal Society of Medicine, ſeems to confirm the obſervation of Mr. Cruikſhank. Although Mr. Jurine could not collect any air from his ſkin, when immerſed in the warm bath, he always found the air confined about the ſkin much vitiated. He fixed well-dried bottles under his arm-pits, and round his waiſt, and having left them there for an hour, accurately corked and removed them, that the contained air might be examined by the uſual teſts. In theſe experiments he always employed the mercurial trough. This air was found, on different occaſions, to contain .7, .7½, .6, .4½ of carbonic acid gas. He next incloſed his arm in a glaſs cylinder containing 685 cubic inches of air. One extremity of this veſſel cloſely embraced his arm, round which it was cemented. To the other extremity was fixed a bent tube, which, during the experiment, was plunged under water in the pneumatic trough. After two hours, the air of the cylinder was found to contain .8 of carbonic acid gas. In another experiment the ſame quantity was obtained after one hour; but the proportion of carbonic acid gas was not greater at the end of two, three, or four hours. Being thus ſatisfied that carbonic acid gas is formed by the ſkin when in contact with the air of the atmoſphere; he concluded, that he ſhould find the ſame gas under the bed clothes which confine the air round the body during ſleep; and in experiments on different individuals he found that this air contained .4, .6, .7, .8 of carbonic acid gas.

In the ſame volume are ſome experiments by Gattoni, which do not lead to the ſame concluſions with thoſe of Jurine: but they do not ſeem to have been very accurately performed, and the teſt of lime water was not employed.

We come in the next place to the reſearches of Mr. Abernethy. From the hand, introduced into a glaſs jar filled with mercury and inverted, he collected, in the ſpace of ſixteen hours, one half-ounce meaſure of air, which had eſcaped in ſmall bubbles from every point of the ſurface of the immerſed hand. Two-thirds of this gas were abſorbed by lime water; and the remainder ſuffered no diminution from the admixture of nitrous gas. When the experiment was repeated under water, a ſmall quantity of azotic gas only was obtained, the carbonic acid having been, in the opinion of Mr. Abernethy, abſorbed by the water. The hand was expoſed five hours, in a jar containing ſeven ounces of atmoſpheric air, which was diminiſhed about half an ounce. One ounce of the remainder was abſorbed by lime water, with precipitation of the lime. By the teſt of nitrous gas the air was found to contain nearly ⅙th leſs of oxygenous gas than it did before the experiment. When a ſimilar experiment was performed with ſeven ounces of azotic gas, rather more than one ounce meaſure of carbonic acid gas was produced in two hours. The trials were repeated with hydrogenous, nitrous, and oxygenous gaſes, and in every inſtance nearly the ſame quantity of carbonic acid gas was obtained.

In the 45th vol. of the Annales de Chimie, there is a ſhort paper by Dr. Trouſſet, who had noticed, like Milly, the appearance of bubbles on the ſkin in the warm bath. He ſeems to have ſeen this only in two individuals, and found the air to be perfectly pure nitrogen. In his own perſon, and in many others, he could obſerve nothing of the kind.

Spallanzani is the laſt experimental philoſopher who has paid particular attention to this ſubject. The detail of his experiments has not been publiſhed, but the reſults are preſerved in a letter to Senebier, introductory to the Memoirs on Reſpiration. He appears to have been completely ſatisfied that air in contact with the ſkin is changed exactly in the ſame manner as by reſpiration. When atmoſpherical air was employed, oxygen diſappeared, and carbonic acid gas was produced: he was of opinion, that the oxygen of the atmoſphere had no ſhare in the production of the carbonic acid gas, becauſe it was equally great when the animal was confined in gaſes containing no oxygen; and he therefore concludes, that the carbonic acid gas was exhaled, and the oxygen abſorbed.

On a review of theſe very contradictory evidences we do not ſeem to be warranted in believing that any gas is ſeparated from the ſkin: but perhaps we may conclude that the air in contact with the organ undergoes a peculiar modification.

Sebaceous Glands of the Skin.—This organ is habitually covered with an oily ſubſtance, which occaſions water to run into globules on the ſurface of the body, which imparts a greaſy ſtain to linen, when it is worn for a long time, and which occaſions duſt, &c. to adhere to the ſkin. This unctuous ſubſtance is more abundant in ſome parts of the body than in others. About the face it is obſerved in conſiderable quantities, and on the hairy ſcalp. Hence, when perſonal cleanlineſs is not ſufficiently attended to, the hair becomes quite greaſy and ſhining. It is abundant in ſituations expoſed to friction, as the axillæ, perinæum, &c.; and when confined in ſuch parts cauſes a very diſagreeable odour. It is found in very ſmall quantity, ſo that it can hardly be obſerved, in the palms and ſoles. Certain races of mankind, as the negroes, have it in great abundance. Probably the ſenſible qualities of the cutaneous diſcharge depend in great meaſure on this matter, the particular nature of which is but little underſtood. It does not ſeem to undergo thoſe changes of augmentation and diminution which are obſervable in the perſpiration. Its obvious utility ſeems to be that of protecting the ſkin from the agency of external cauſes, and keeping it in a ſtate of ſoftneſs.

Is this matter ſimply an exhalation from the cutaneous veſſels, or is it produced by glandular apparatus? In ſome parts of the ſkin, as about the noſe, and in other ſituations of the face, the external ear, &c. there are very manifeſt ſmall roundiſh bodies, with a ſimple aperture, from which a ſebaceous matter may be ſometimes expreſſed like a fine thread. Morgagni alſo admits their exiſtence in the neck, back, perinæum, buttocks, &c. Haller does not conceive that they are proved to exiſt in all parts, and we certainly do not find them: yet this oily matter is formed over the whole body. The examples of the fat of the cellular interſtices and of the medullary fluid of bones ſhew us that the exhalants can produce matters of this kind.

Properties of the Dermoid Syſtem.

1. *Properties reſulting from Organization.*—Theſe are found to exiſt in the ſkin in a very ſtriking degree: the changes of ſize, in which different parts, particularly the limbs, ſwell to twice or three times their natural bulk, and then recover their former ſtate, prove theſe properties; and the various tumours, external aneuriſms, ſudden diſtentions from great bruiſes, collections of fluid in the abdomen, pregnancy, enlargements of the teſticle, &c. afford additional proofs. In all theſe caſes the ſkin is firſt expanded, and then is reſtored when the diſtending cauſe ceaſes to act. A ſquare inch of integument has been found able to ſuſtain a weight of 200lb..

The contractility of the ſkin occaſions the retraction of its edges when it is cut: and this occurs in the dead ſubject; but it ſeems to be heightened by the vital powers as it occurs to a much greater degree during life.

The extenſibility of the ſkin is leſs in many caſes than it would appear to be on firſt ſight, as the neighbouring integuments are drawn over a tumour. Thus in large ſwellings in the ſcrotum, the ſkin of the penis covers part of the tumour, &c.: in extenſive cicatrices the ſkin of the ſurrounding parts is drawn towards the centre of the ulcer.

In moſt extenſions the thickneſs of the dermoid tiſſue is diminiſhed. When it is diſtended by the infiltration of water in its interſtices, as in anaſarca, its thickneſs increaſes, while the denſity is diminiſhed. It ſeems to loſe the power of extenſion, ſo as to burſt under the action of a diſtending cauſe, from chronic inflammation. Moſt of the chronic affections, which alter the tiſſue of this organ, deſtroy its contractile power.

Vital Properties.

2. *Properties of the Animal Life.*—Animal ſenſibility exiſts in this organ in a very high degree: it preſides over the general ſenſe of feeling, which is more acute in this than in other tiſſues, and alſo that of touch, which is very diſtinct from the former. The general ſenſe, called by the French tact, is the power of perceiving the impreſſions of ſurrounding objects: in this ſignification it ſeems to mean the ſame as the Engliſh word feeling, which is the office of a nerve in general; as thoſe organs only are ſo affected by external bodies as to produce ſome change by which the mind is rendered conſcious that the bodily organ has been modified. Thus heat and cold, roughneſs and ſmoothneſs, hardneſs and ſoftneſs, moiſture and dryneſs; preſſure cauſing pain; acrid qualities; titillation producing itching, &c. are all perceived by the nerves. This kind of tact belongs to the whole body; and does not ſuppoſe any peculiar arrangement of the organ; it is merely the animal ſenſibility conſidered in a ſtate of exerciſe. Thus, when the particular modifications of this ſenſibility belonging to the other ſenſes have been deſtroyed; when the eye is inſenſible to light, the ear to ſounds, &c. the organs ſtill retain the power of perceiving the preſence of bodies and their general attributes.

The ſenſe of touch is the power belonging to the ſkin alone, of examining more minutely and accurately thoſe properties of bodies, which we have juſt named. For this purpoſe we employ chiefly the ends of the fingers; thoſe of the toes ſeem to be organized exactly in the ſame way, but are incapable of being turned to this uſe by the hardneſs of their coverings. Theſe parts are conſpicuous for the ſize of their nerves, and for the number and prominence of the papillæ. This organization gives to them a more exquiſite ſenſibility of the ſame kind with that belonging to the ſkin in general. The form of the organ in the human ſubject, where it is compoſed of ſeveral moveable parts, adapts it particularly to ſerve as an inſtrument of touch, by facilitating its application to external objects; and this advantage may be more particularly ſeen in bodies of a rounded figure. We rub the fingers gently againſt the object, ſo as to apply the papillæ ſucceſſively to the different points of its ſurface. Whether any phyſical change takes place in the organ, whether the papillæ for example are erected or no, is entirely unknown.

The diſtinction of colours by blind perſons, if ſuch a power has really exiſted in any inſtances, muſt have ariſen from modifications in the ſurface produced by the colouring matter. We know that the touch in all caſes of blindneſs acquires great acuteneſs, as it muſt be ſo much more exerciſed and depended on, than in individuals who can ſee.

The temperature of bodies is eſtimated by a compariſon; thoſe are called cold, which are of a lower temperature than what we had felt immediately before; and *vice verſâ*. Or we refer to the ſtate of our own ſurface, and call the objects, from which heat paſſes to us, warm, and thoſe of the oppoſite kind cold. The ſame fluid will appear cold to one hand

and warm to the other, if we have previouſly immerſed one in a warmer, and the other in a colder medium.

It has been conceived that the ſenſe of touch is of great uſe to us in correcting the errors of the other ſenſes, and particularly of the ſight. This peculiarity belongs to it certainly, that the organ is modified by the very body whoſe properties we are examining; while, in the caſe of viſion for example, the eye is affected not by the object itſelf, but by the rays of light. Perhaps we are leſs deceived by the other ſenſes, and by that of ſight itſelf, than has been commonly imagined. Without any aſſiſtance from the ſenſe of touch, for which his organization entirely diſqualifies him, the horſe meaſures the hedge or ditch with his eye moſt accurately, and clears the diſtance with great exactneſs. Newly born animals ſeem to commit no errors in ſeeking their food or their parents, &c. On the other hand, the touch is not free from error. The experiment of rolling a round body under two fingers decuſſated, which give us the ſenſation of two bodies, ſhews this. Moreover, the touch no more informs us of the real nature of things, than any other ſenſe; we acquire a knowledge of their properties through certain interpoſed media, and alterations in them very much modify the perception. When the epidermis is removed, external bodies cauſe pain, and do not excite the impreſſions, which inform us of tangible properties; again, when the cuticle is preternaturally thick, as in the hands of labouring men, no ſenſation takes place.

This ſenſe is alſo ſubject to various morbid conditions. In hypochondriacs there is ſometimes a feeling as of cold air; and the ſlighteſt contact of air is intolerable. Ann of Auſtria found the fineſt linen manufactures unpleaſantly rough; and ſome have not been able to endure the touch of ſilk, or of the down of a peach.

Habit, too, has a powerful influence in modifying the impreſſions which we receive from the touch. The heat of a glaſs-houſe, which is ſuſtained without any unpleaſant feeling by the workmen for ſeveral hours, is intolerable to a perſon unaccuſtomed to it.

The touch differs from the other ſenſes in not requiring a peculiar mode of ſenſibility for its exerciſe; the hand is rather more ſenſible than the reſt of the ſkin, but we can touch with other parts of our ſurface. In the other ſenſes there are peculiar kinds of ſenſibility diſpoſing the organs to be acted on by particular objects, and rendering them unſuſceptible of other impreſſions. The exerciſe of the touch is determined by volition, and is generally conſequent on the employment of the other ſenſes.

Moſt of the other ſenſes require an expreſs organic arrangement, as well as a peculiar ſenſibility in the organ; the touch, on the contrary, requires only a particular form in its organs. If they have the animal ſenſibility, and can embrace objects by ſeveral points, they can diſtinguiſh the tangible properties. The touch will be imperfect, if the organ is in contact with the body only in one or two points; yet it will take place. Thus we can touch with the hollow of the axilla, at the bend of the elbow, or the knee. But the ſenſe is exerted more advantageouſly when the points of contact are multiplied. The ſtructure of the human hand is particularly well contrived in this point of view; it ſhews us that man is calculated, much more than the animals, for communication with ſurrounding objects; that the domain of his animal life is therefore much more extenſive; that his ſenſations are more preciſe, as they poſſeſs an additional means of perfection; that his intellectual faculties are capable of filling an infinitely greater ſphere, becauſe they are grounded on the exertion of a much more perfect organ.

The ſenſibility of the ſkin ſeems to reſide eſſentially in the papillæ, which is the part of the integuments truly belonging to the animal life, as the vaſcular plexus, compoſing the reticular body, is connected with the organic functions. Its very acute ſenſibility requires a protection from too ſtrong impreſſions; and this is afforded by the epidermis. When that is removed, even the impreſſion of the air is painful, and cauſes a ſenſation, which we call ſmarting, which belongs perhaps excluſively to the dermoid ſyſtem. It is felt in burns, bliſters, eryſipelas, and in all the inflammations affecting the reticular body of the ſkin. Itching is another mode of ſenſation peculiar to this ſyſtem.

Beſides the impreſſions, which teach us the properties of bodies, the exerciſe of this organ produces feelings of pleaſure and pain. So far as the ſenſe of touch is concerned, pleaſure may be conſidered as that condition of the body, which we ſhould wiſh to have continued. The more exquiſite feelings of this kind are produced by friction of the papillæ. Without referring to venereal ſenſations, we may mention a practice of the Chineſe, of introducing a ſmall pencil into the ear and moving it round ſo as to excite a very acute pleaſurable feeling. Tickling muſt be ſomething of this kind; it is peculiar to the ſkin, and in many individuals excites ſenſations which are almoſt intolerable. Great differences in this reſpect are obſerved in different perſons. Pain is the very reverſe of pleaſure; and, in the ſkin, is the moſt acute, when the naked organ, where it poſſeſſes many papillæ, is irritated.

The animal ſenſibility of the ſkin, like that of the mucous ſurfaces, is under the powerful influence of habit, which transforms ſucceſſively into indifference, and into pleaſure what was at firſt painful. The air in the ſucceſſion of the ſeaſons, heat in the various ſtates of the atmoſphere, water in the bath, or in the humid vapours with which it loads the medium in which we live, our clothes, of which the woollen are at firſt very unpleaſant, in ſhort, every thing which acts on the ſkin by ſimple contact, produces ſenſations which are inceſſantly modified by habit. Obſerve the varieties of dreſs in different countries; ſometimes the upper limbs are uncovered, ſometimes the lower; in ſome inſtances more or leſs of the trunk is expoſed to the air; often the ſavage is entirely naked. The parts which are left naked in each people, ſupport the contact of the air without any painful ſenſation. Expoſe, on the contrary, the parts which are habitually covered, particularly if the atmoſphere be cool, a painful ſenſation will be produced at firſt, but, as the parts become gradually habituated to the contact, they are at laſt inſenſible to it.

But habit has no power over that heightened ſtate of the cutaneous ſenſibility, which reſults from an organic affection, as inflammation for example. The ſlighteſt contact of a foreign body is extremely painful in this caſe; and conſequently the ſkin can no longer exert its function of touch. Even the tact, or the power of diſtinguiſhing general ſenſations, is deſtroyed. The impreſſion of all bodies is uniform; it is that of pain.

The animal ſenſibility of the ſkin may be diminiſhed or deſtroyed, as in paralyſes; but the whole organ is never affected; and in this reſpect there is very ſeldom even hemiplegia. Theſe caſes afford a further proof that the cutaneous exhalation and capillary circulation are not influenced by the nerves, ſince both go on very well as they do in the paralyſis of the moving organs.

Properties of the Organic Life.—The organic ſenſibility and the inſenſible contractility exiſt in the ſkin in a very high degree, and reſide particularly in the exterior capillary ſyſtem, which forms the reticular body. On theſe properties depend immediately, 1, the capillary circulation; 2, the cutaneous exhalation; 3, the abſorption; 4, the nutrition of the dermoid ſyſtem; and 5, the ſecretion of the cutaneous oil, where ſebaceous glands exiſt. Beſides theſe numerous functions, we muſt reflect that the ſkin is conſtantly expoſed to the action of external cauſes, which keep it in a ſtate of habitual excitation, as the contents of mucous ſurfaces act on thoſe ſurfaces.

The ſkin does not ſeem to poſſeſs the ſenſible organic contractility; irritating applications act only on the capillaries, and therefore produce an effect, which is not obvious to the eye. Yet the corrugation of the integuments under the ſtrong action of cold, reſembles in ſome reſpects the ſenſible organic contractility; this, which takes place in the corion, ſeems to hold the middle between the two kinds of organic contractility.

Paſſive Sympathies.—The animal ſenſibility is often brought into action ſympathetically in the ſkin, by the affections of other ſyſtems. There are various examples of itching, &c. without any derangement of the part, to which the ſenſation is referred.

Very often the feeling of heat or cold occurs in the ſkin, when there is no cauſe affecting the organ to produce ſuch ſenſations; there ſeems to be an erroneous reference of the unpleaſant feeling to its ſource as in the caſe of pains felt in amputated limbs. The ſhiverings which occur at the commencement of moſt acute local diſeaſes are of this kind: there is often a ſudden and ſympathetic ſenſation of cold on the ſkin at the moment of the expulſion of the ſemen; the ſhivering of fear, and the ſweat which often accompanies it, ſeem to be of the ſame nature. A ſpecies of ſympathetic cold is alſo often referred to the ſkin at the commencement of digeſtion.

The feeling of heat often occurs ſympathetically in the ſkin. The fluſhings, which occur ſo often and irregularly in different fevers, are well known, and are not attended with any diſengagement of caloric. Theſe feelings of heat and cold are produced without any alteration of temperature, as ſympathetic pains occur without the action of thoſe obvious cauſes, which give riſe to them under other circumſtances. In fact, the ſympathies of the animal ſenſibility call into action, in each ſyſtem, the feeling which is habitual to it. The ſame cauſe which produces the ſenſation of heat or cold in the ſkin, would have given riſe to that of laſſitude in the muſcles, &c.

The organic properties of the ſkin are frequently called into action by ſympathies: thus cold drinks ſuppreſs perſpiration. Augmented cutaneous exhalation follows almoſt immediately the introduction of warm fluids into the ſtomach. The ſweat of fear and that of conſumption are of the ſame nature. Diſeaſes exhibit to us innumerable varieties of dryneſs and moiſture of the organ, phenomena which are generally ſympathetic.

Active Sympathies.—The irritation of the ſkin in tickling, in very ſenſible individuals, excites various organs ſympathetically; as the heart, producing fainting; the ſtomach, vomiting; and the brain, convulſions. Affections of the cutaneous exhalants, or of the capillary ſyſtem, from which they ariſe, act ſympathetically on various organs. Thus the warm bath diſturbs the proceſs of digeſtion; while its influence in many caſes allays diſorders of the ſtomach. The action of cold on the ſurface, particularly during ſweating, produces ſeveral ſympathetic effects. We expreſs what occurs very inaccurately, when we refer it to the tranſlation or repulſion of the perſpiratory matter. The organic ſenſibility of the pleura is ſympathetically affected by the application of cold to the ſkin; juſt as an uterine or naſal hemorrhage may be ſtopped. The ſuppreſſion of tranſpiration is an acceſſory circumſtance completely foreign to the internal inflammation. If there were no perſpiration at the time that the cold is applied, the inflammation would ſtill come on.

The ſhaking of the muſcles, and the concentration of the pulſe, produced by the weakened action of the heart, are phenomena cauſed entirely by the action of cold on the ſkin.

The numerous phenomena occaſioned by the ſudden diſappearance of cutaneous eruptions ſhould be referred to modifications of the vital properties of the organs, and not to any morbific matter repelled from the ſkin.

The ſerous ſurfaces and the cellular ſubſtance on one ſide, and the ſkin on the other, are often in oppoſition in diſeaſes. Patients never ſweat during the formation of dropſies; and this dryneſs of the ſkin is often more remarkable than the ſmall quantity of urine.

Characters of the vital Properties.—1. They vary in the different regions of the body. The palms and ſoles are the moſt diſtinguiſhed for their animal ſenſibility: the hypochondria are ſo ſenſible in ſome individuals, that tickling will produce convulſions: the anterior and lateral parts of the trunk are more ſenſible than the back. The organic properties do not differ leſs; of which the great ſuſceptibility of the face to the influx of blood is a proof. Particular parts are ſubject to particular cutaneous diſeaſes, &c.

2. Intermiſſion of action in one reſpect, uninterrupted continuance in another. The former character belongs to this ſyſtem, as to all the ſenſes, in its animal ſenſibility. Immediately before ſleep comes on, external objects produce but an obſcure ſenſation, which is entirely loſt in that ſtate, in which animals ſeem to part with half their exiſtence. Yet the touch ſeems to be exerted occaſionally while the other ſenſes are in repoſe: pinch the limb of a perſon ſleeping, and he will move it without waking, or retaining any recollection of the occurrence. In its organic ſenſibility the life of the cutaneous ſyſtem is uninterrupted; conſequently the functions, over which this property preſides, have an oppoſite character to the preceding. The inſenſible tranſpiration goes on continually, although it is more active at ſome times than at others.

3. Influence of ſex. The animal ſenſibility is more acute in women, in whom every thing belonging to the ſenſes is more developed, while the power of the muſcles predominates in man. No very ſenſible difference can be remarked in the organic properties.

4. Influence of temperament. The colour and other ſenſible properties of the ſkin vary in individuals, and theſe variations even conſtitute characters of the different temperaments. When we ſee theſe differences of organization, can we be ſurpriſed at finding that the ſenſe of touch is acute in ſome, dull in others; that ſome perſons are very ſuſceptible of tickling, and others almoſt inſenſible to it? That the organic ſenſibility admits a great quantity of blood into the capillaries of the face in ſome, and rejects it in others; that ſome have a moiſt and others a dry ſkin; that there are diſpoſitions in individuals to particular cutaneous affections, chronic or acute? &c. &c.

Development of the dermoid Syſtem.—The ſkin, in the early times of conception, appears as a viſcid coating, which is gradually condenſed into a tranſparent layer, torn by the ſlighteſt violence, and allowing the ſubjacent organs, particularly the blood-veſſels, to be eaſily ſeen through it. Its conſiſtence increaſes until it acquires the appearance exhibited at the time of birth. In its mucous ſtate cellular ſubſtance and veſſels compoſe it entirely: when the fibres of the corion are added, it becomes firmer. The external ſurface exhibits but few of the wrinkles deſcribed above: they are prevented from appearing by the large quantity of ſubjacent fat. The inner ſurface adheres but ſlightly to the cellular layer under it. It contains more blood than at any other period of life. The animal ſenſibility is not yet called into exerciſe; there are no cauſes to excite it. Is the organic ſenſibility in action at this time? It muſt be ſo in a certain degree to produce the unctuous ſecretion, by which the ſurface is covered.

This ſyſtem undergoes a ſudden revolution at the inſtant of birth. Hitherto it has received only black blood, and is conſequently more or leſs livid at birth. This colour gives place to red, produced by the arterial blood now firſt formed: and the ſtate of the ſkin in this reſpect may be conſidered as an index of what is paſſing in the lungs. All parts of the organ are penetrated uniformly by the red colour. A ſudden excitation is thus communicated to the organ, exalting its vital properties, and rendering it more ſuſceptible of the impreſſions of ſurrounding objects. The ſurrounding temperature, the air, clothes, the water uſed in waſhing it, communicate to the ſkin an excitation, which is the more ſenſible in proportion to its novelty. The ſympathies connecting the ſkin to the other organs now become neceſſary: thus the internal organs quickly feel the excitations applied externally

The organic ſenſibility is augmented at the ſame time; tranſpiration is eſtabliſhed; various ſubſtances are ſeparated by it; others perhaps abſorbed; and various diſeaſed affections ſhew themſelves.

The organ ſtill continues ſoft for ſome time after birth; and melts entirely into jelly very eaſily by ebullition. Its denſity increaſes gradually, but has not arrived at its greateſt ſtate till towards the thirtieth year. As this augmentation proceeds, the fibrous ſubſtance is increaſed in proportion to the gelatinous. At the ſame time the adheſion of the internal ſurface to the cellular ſubſtance becomes ſtronger, and the wrinkles of the face are gradually formed. No remarkable change is produced in this organ at puberty: ſweats are more abundant after this time; in children the reſidue of nutrition paſſes off by the kidneys rather than by the ſkin.

The organ ſtill retains a great activity after the age of growth, and very eaſily influences other parts of the frame: hence the peripneumonies, pleuriſies, &c. produced by the action of cold.

The increaſe of the fibrous ſubſtance renders it more firm: leſs blood ſeems to be ſent into its veſſels, and it is leſs ſubject to thoſe eruptions ſo common in infancy and youth.

In declining age the dermoid ſyſtem becomes more and more denſe: it reſiſts ebullition for a long time, but yields a firmer and more conſiſtent, though leſs abundant jelly. It is ſtronger but leſs pliant. The blood penetrates it in ſmaller and ſmaller quantity: the redneſs of the cheeks diſappears. The adheſion to the cellular ſubſtance is much more cloſe. All the wrinkles are more ſtrongly marked, and ſeveral are now perceptible for the firſt time.

The vital powers of the ſkin are more weakened than thoſe of other ſyſtems in the old man, becauſe it has been more excited by external objects during life: the habit of feeling has blunted its ſenſibility. The touch is now exerciſed but rarely; as this ſenſe is employed in a great meaſure in ſubſervience to thoſe of ſight, hearing, &c. to rectify or confirm our other ſenſations, the old man, being acquainted with what ſurrounds him, has no motive for the uſe of his organ of touch. Contraſt, in this point of view, the two extremes of life. The infant, to whom every impreſſion on the ſight, hearing, &c. is new, wiſhes to touch, to ſeize every thing: his hands are in conſtant motion. Touching is a great pleaſure to him, becauſe all new ſenſations are agreeable. If an old man were placed in the midſt of objects, which had never before impreſſed his ſenſes, he would exerciſe his touch more frequently; but, among the things to which he is habituated, there is nothing to excite him. Hence old age is no longer the time of enjoyment. Almoſt all our pleaſures are relative; as habit renders theſe leſs lively, they ceaſe in conſequence of having exiſted; thus the advance of years, by leaving us few new ſenſations, diminiſhes the ſources of our happineſs. For the contrary reaſon the happieſt age is that of infancy; becauſe the whole domain of ſenſation lies before us unexplored; at every ſtep of his advancement man leaves behind him a ſource of enjoyment. His career ends in indifference, a ſtate very ſuitable to that period, as it diminiſhes the interval between life and death.

The following phenomena ſhew that the organic, as well as the animal ſenſibility, is remarkably diminiſhed in the old man. Contagions are leſs eaſily abſorbed. The ſweat is leſs abundant, and hardly ever exhibits thoſe augmentations which are ſo frequent in the adult. The greaſy covering is leſs copious, and hence the ſurface is drier. The various morbid affections, ſuch as eryſipelas, and the various eruptions, are leſs common and much ſlower. The power of reſiſting cold is ſenſibly diminiſhed.

Epidermoid or cuticular Syſtem.—The ſlighteſt examination is ſufficient to ſhew very ſtriking differences between this and the preceding ſyſtem, although phyſiologiſts have generally deſcribed this merely as a dependance of the former. The organization, properties, functions, mode of growth, in ſhort, every circumſtance is different in the two caſes.

Under this head we conſider the exterior epidermis; that which covers a part of the mucous ſyſtem; and the nails. Many characters approximate the latter to the epidermis, although the external appearance is very different.

The *exterior epidermis* is a tranſparent layer, differing in thickneſs in different parts, every where covering the ſkin, and immediately expoſed to the excitation of external bodies.

It has the ſame inequalities as the cutis, ſince they are every where exactly contiguous. Various pores penetrate it, and terminate on its ſurface: the more conſpicuous ones tranſmit the hairs; others give paſſage to exhalants. The latter are not eaſily ſeen; but if, when the ſkin is dry, we ſuddenly begin to ſweat, we can diſtinguiſh them by the ſmall points of moiſture then exhibited over the whole cutaneous ſurface. We cannot actually ſee the pores in the dead cuticle, even with the aſſiſtance of the microſcope; and the fluid under a bliſter does not eſcape through them: but the phenomena exhibited during life leave no doubt of their exiſtence. The internal ſurface adheres moſt cloſely to the outer ſurface of the cutis. We conceive the union to be by means of the exhaling and abſorbing veſſels and the hairs. Dr. Hunter thought that the veſſels could be demonſtrated. On ſeparating the cuticle after long maceration, particularly in the ſole of the foot, a vaſt number of extremely fine and ſoft threads are ſeen paſſing between it and the cutis: they break after being extended to about one-eighth of an inch. Theſe may be veſſels; but it is only a conjecture. On examining the ſurface of the ſeparated cuticle, numerous prolongations of various lengths are obſerved, appearing like ſmall ends of fine threads, or as mere inequalities, and diſpoſed obliquely. Theſe may be abſorbents and exhalants. Whatever the medium of connection may be, the adheſion of the parts to each other is very ſtrong.

Various cauſes deſtroy this adheſion of the epidermis, and occaſion its ſeparation. Acute inflammations, as eryſipelas, phlegmon, &c. are followed by its detachment; and various eruptions, not of an inflammatory nature, cauſe its detachment in a dry ſcaly form; which has given riſe to the notion that it is made up of ſcales in its natural ſtate. When the ſkin is unequal on the ſurface, friction detaches it in ſmall ſcales, which give a very rough appearance to the part. Fevers are not unfrequently followed by deſquamation of ſkin. The action of veſicatories is familiarly known. In the dead ſubject, putrefaction, maceration, and ebullition are the moſt effectual means of accompliſhing the ſeparation.

The thickneſs of the epidermis is in general very uniform: it does not ſeem to follow thoſe varieties which we obſerve in the cutis of the trunk, limbs, &c. It is only in the palms and ſoles, and on the correſponding ſurfaces of the fingers and toes, that its thickneſs is increaſed: and here the augmentation is ſo conſiderable, that there is no proportion between theſe and other parts of the body.

There ſeem to be in this part ſeveral additional laminæ; and the inner ſurface, after ſeparation, does not exhibit thoſe proceſſes already ſpoken of. This exceſſive thickneſs prevents the action of bliſters. In repeated trials Bichat found that they produced no effect. The tranſparence of the epidermis is deſtroyed by this thickneſs: it is here whitiſh, and even opaque. Hence, in the negro, it conceals the black colour of the reticular body; which, however, is, at the ſame time, leſs black here than in other parts. The epidermis in theſe ſituations is manifeſtly compoſed of ſucceſſive laminæ, adhering with ſuch force, as to be very difficultly ſeparated: in all other parts we can diſcern only a ſimple layer. No fluid can be noticed in this tiſſue: when cut in various directions, either in the living or dead ſubject, nothing exudes. Its ſcales are always perfectly dry: the abſorbents and exhalants merely traverſe it. No blood in the living ſtate, nor injection after death, enter it in any caſe. It never participates in the diſeaſes of the ſubjacent organ, except by being elevated when that is ſwollen, and then detached. Nerves and cellular tiſſue are completely foreign to it. Thus we ſee that none of the general ſyſtems, common to all organs, enter into the compoſition of the epidermis: it has not the common baſis of all organized parts; and in this point of view may be regarded as inorganic. It ſeems to contain no fibre in its compoſition: it poſſeſſes very little power of reſiſtance, breaking under a ſlight diſtention, except in the ſoles and palms, &c. where it is ſo thick.

The action of air produces hardly any effect on it. When a large piece is expoſed, it becomes rather harder, and more conſiſtent, and is torn more difficultly. Next to the hair and nails, it is the tiſſue leaſt changed by deſiccation. It is rendered a little more tranſparent, but immerſion in water reſtores it to its former ſtate. When the ſkin paſſes into a ſtate of putrefaction, the cuticle is not at all changed. It is ſeparated from the cutis, but not rendered at all putrid; if it be thoroughly waſhed, it has no bad odour. When preſerved in moiſt air, it is not changed; and it may be regarded as the moſt incorruptible of animal ſubſtances, after the hair and nails.

Moiſture applied for a long time whitens the living cuticle, and throws it into numerous wrinkles. This effect is obſerved in the application of poultices, and ſeems to ariſe from the tiſſue becoming penetrated with the fluid; it takes place to the greateſt degree in the foot and hand, and often is hardly ſenſible in other parts. The ſenſibility of the ſkin is rendered more obtuſe by this change in the cuticle. The water imbibed by the part is afterwards evaporated, the wrinkles diſappear, and the cuticle recovers its former ſtate. When ſeparated from the body, and immerſed in water, it is whitened: it undergoes no putrid alteration, but is covered by a whitiſh pellicle formed of ſeparate moleculæ. At the end of two or three months it is ſoftened, and may be torn very eaſily, but does not ſwell: it is never reduced to a pulp analogous to that of other organs when macerated. Boiling never produces criſpation or corrugation of this tiſſue: prolonged ebullition renders it leſs reſiſtant, ſo that it may be torn very eaſily, but never reduces it to gelatine, nor gives it a yellow colour. The laminæ which compoſe it in the hands and feet are eaſily ſeparated after long boiling. The tanning principle has no action on it; nor has alcohol.

When well dried in the air, and expoſed to the flame of a candle, it undergoes no criſpation, as a piece of ſkin does when treated in the ſame way: it exhales a fetid odour analogous to that of burnt horn. It burns with great facility, ſo that if it be lighted at one end, it will often be entirely conſumed. A blackiſh fluid is obſerved in the flame, like that of burnt feathers. This is clearly of an oily nature, keeps up the combuſtion by its great abundance, and is found in ſo large a quantity only in the hair and nails: this produces a diſagreeable odour. A blackiſh coal remains after combuſtion. Light does not ſeem to affect the epidermis, which is not changed when expoſure to the ſun has altered the appearance of the ſkin.

Nitric acid turns it yellow, but diſſolves it with great difficulty. Sulphuric, on the contrary, when not much diluted, acts very powerfully on it, rendering it very thin and tranſparent, or diſſolving it entirely by long immerſion. Alkaline ſolutions diſſolve it, but with difficulty: pure alkali acts on it rapidly; as alſo does lime, according to Chaptal.

If, ſays Dr. Thomſon, the cuticle be tinged with nitric acid, the application of ammonia to it is well known to give it inſtantaneouſly a deep orange colour. Now, as Hatchett has ſhewn that this change is alſo produced upon coagulated albumen in the ſame circumſtances, and as the epidermis reſembles that ſubſtance in all the properties above detailed, it can ſcarcely be doubted that it is any thing elſe than a peculiar modification of coagulated albumen. Syſt. of Chemiſtry, v. 5, p. 574.

Properties.—It has very little extenſibility, as the ſmalleſt cutaneous tumour cauſes it to crack, and be detached in ſcales. Yet it is not entirely deſtitute of this property, as its elevation in bliſters proves. It has no contractility: when no longer diſtended, the portion elevated in a bliſter collapſes in wrinkles, and does not regain its original ſize. It has no animal ſenſibility in any part: it may be pricked, cut, torn, or injured in all parts without exciting any ſenſation. It differs from other organs, as cartilages, tendons, &c. which alſo have no animal ſenſibility, in being altogether unſuſceptible of that property, which they often acquire under certain kinds of excitement. The epidermis is equally deſtitute of the organic ſenſibility, and organic inſenſible contractility: it poſſeſſes no circulation, and is ſuſceptible of no diſeaſes, which depend on the organic properties. We have no proof, in ſhort, that it enjoys any vital powers at all; ſo that we may conſider the whole ſuperficies of the body as compoſed of dead matter. "Its life," ſays Bichat, "is extremely obſcure; I even doubt whether it can be ſaid to poſſeſs life. I am inclined to regard it as a ſemi-organized, or rather inorganic body, placed by nature at the point of communication between external dead matter and the living ſkin, and ſerving as a gradation between them."

The action of external bodies wears it away, and it is conſtantly reproduced. Scrape the ſurface with the blade of a knife, and an abundant greyiſh duſt will be detached. This matter accumulates in greater quantity, when the ſkin is not frequently waſhed; under ſuch circumſtances there is often a conſiderable layer.

It is reproduced very completely after being removed; and differs in that circumſtance from moſt other tiſſues. How this is effected has been a point greatly diſputed by phyſiologiſts; but the explanations have been entirely mechanical and unſatisfactory. That it is depoſited by the veſſels of the ſkin cannot be doubted; and we ſhall probably underſtand how the proceſs is effected, when we underſtand how the veſſels make bone, muſcle, nerve, &c. This reproduction only takes place on the ſkin: the thin pellicle covering the cicatrices of other tiſſues has a completely different texture. The different excreſcences affecting the cuticle, as corns, &c. reſult from the exerciſe of this reproductive power. They are all inſenſible, have no veſſels nor nerves, and poſſeſs the ſame conſiſtence and colour as the epidermis. External preſſure ſeems to promote their formation very powerfully; tight ſhoes produce corns; and much handling of heavy inſtruments in hard work produces the thick cuticular covering of the hand in blackſmiths and other mechanics.

The cuticle of the palms and ſoles is however originally thicker than that of other parts; this may be ſeen in the fœtus.

In the dead body the cuticle has a remarkable effect in preventing the evaporation of the fluids; none of which are diſſipated ſo long as this covering remains entire. If the body be expoſed in a high temperature, as of 100° or 120°, it does not ſeem to become dried; and where the limbs are diſtended in anaſarca, if it has not cracked, none of the fluid eſcapes. Remove the cuticle, and the cutis quickly becomes dry, tranſparent, and horny, and the ſubjacent parts are ſubſequently affected in the ſame way.

The epidermis is ſeen very clearly in the fœtus, where its developement is greater in proportion than that of other ſyſtems. It may be recognized when the ſkin leaves that pulpy ſtate which we have ſpoken of. At the end of the fifth month it is thicker in the palms and ſoles than in other parts. It appears to undergo no change at birth; but grows rather thicker afterwards as age advances. In the old ſubject it differs from that of the adult only in being ſubject to ſcale and crack, and thereby appearing dry and rough.

Internal Epidermis.—Moſt authors have admitted an epidermis on the mucous ſurfaces; and they have generally repreſented that this is the only part of the integuments that lines the mucous cavities. But a little examination will ſhew us that this expanſion forms only a ſuperficial ſtratum, and that if it be detached by hot water from the tongue, palate, &c. an organ analogous to the corion is left behind.

1. *Epidermis at the Origin of the mucous Surfaces.*—It is very diſtinct at all the origins of the mucous ſyſtem, at the glans, urethra, anus, naſal cavities, mouth, &c. It may be demonſtrated in theſe ſituations by the excoriations which ſometimes affect them, by detaching it with a fine lancet, by the action of hot water, by maceration, &c. It is much more delicate in theſe ſituations than where it covers ſkin, and becomes more and more ſo as it penetrates deeper. In theſe parts it is eaſily reproduced. It is deſtitute, like the exterior epidermis, of vital properties; and its nature ſeems to be in all reſpects the ſame; it yields the ſame reſults, when expoſed to the ſame agents.

2. *Epidermis of the more deeply ſeated mucous Surfaces.*—As we advance further into theſe organs, the epidermis becomes gradually thinner, and ſoon is no longer perceptible. The moſt delicate inſtruments and methods do not enable us to demonſtrate it in the ſtomach, inteſtines, urinary and gall-bladders, veſiculæ ſeminales, and the various excretory paſſages. No epidermis is elevated on the ſurface of theſe organs by boiling or maceration; nor by bliſters: nor is there any thing like a ſeparation of ſuch a covering in any diſeaſes. We ſhall be diſpoſed to conclude, from theſe conſiderations, that there is no cuticle on the deeply ſeated mucous ſurfaces, and that the large quantity of mucous fluids poured out in theſe ſituations ſupplies its place by protecting the corion from the impreſſions of noxious matters. The only circumſtance that could induce us to heſitate, is the occaſional ſeparation of ſubſtances like membranes, which might be regarded as exfoliations of an epidermis. Numerous examples occur in medical writers of ſuch matters being voided from the bladder, ſtomach, and inteſtines. On this ſubject we poſſeſs no very preciſe data.

The Nails.—We connect the hiſtory of theſe organs with that of the epidermis, as they adhere to it very ſtrongly, and come away with it in maceration. Their form in the human ſubject differs very much from that which they have in animals: they are generally thick and conical in the latter, thin and flattened in the former. They conſiſt of hard, tranſparent, and elaſtic plates, of a ſubſtance reſembling that of the horns of animals, covering the extremities of the fingers and toes on the aſpect of extenſion. Thus they are not adapted to purpoſes of offence, but are better ſuited to the ſupport of the broad ends of theſe members, which confer on the human ſubject a more perfect power of touch. Their length is limited by the univerſal practice of cutting them to a level with the end of the finger or toe: if left to themſelves, they are prolonged, and at the ſame time bent ſo as to cover the ends of thoſe parts. The natural limit of their growth ſeems to be that period at which they acquire a ſharp cutting edge: for they are then gradually worn away at the margin.

Three parts may be very eaſily diſtinguiſhed in the nail: a poſterior portion, covered on both ſides by integuments: a middle part, which is the moſt conſiderable, adhering by its concave, and unattached on its convex ſurface; and an anterior, free from adheſion in both reſpects.

The poſterior diviſion is about one-ſixth of the whole: it ends behind in a very thin ſerrated edge, by which the nail ſeems to grow out of the ſkin. This part is ſoft and flexible, and of a white colour: it is bounded by a ſtraight line, which, with the two margins, give to the organ a ſquare figure. The convex ſurface adheres intimately to the epidermis, which covers it in the following manner. The cutis terminates over the root of the nail in a ſemilunar edge, in front of which is a ſmall cavity adapted to, and filled by, the white part of the nail. Along the concavity of this creſcent the cuticle forms a ſmall and diſtinct fold, which may be cut without any feeling of pain, and which is reproduced. It adheres cloſely to the root of the nail, and is produced anteriorly for ſome length on its ſurface, unleſs it be cut away. Many deſcribe it as being continued over the whole convex ſurface. Behind it appears to be loſt in the ſoft and thin poſterior margin. Without the adheſion, which connects the ſemilunar border of ſkin to the nail, there would be a ſpecies of cul-de-ſac between theſe parts. Some have conceived that the extenſor tendon reaches to the poſterior edge; but its termination at the tubercle of the laſt phalanx is very diſtinct; and there is a ſpace of two or three lines between this and the nail. The concave ſurface of this poſterior diviſion adheres in the ſame way as that of the middle part.

The convex unconnected ſurface of the middle diviſion is ſmooth, whitiſh behind for a ſmall ſpace terminated by a ſemicircular edge, and red in the reſt of its extent in conſequence of the colour of the ſubjacent parts. On the ſides it is covered a little by the ſkin, which is continuous with the ſemilunar projection already deſcribed. The fold of cuticle is alſo continued, and adheres to the margin of the nail. The concave ſurface of this part is laminated longitudinally, and the plates end in very thin and membrane-like edges; but this laminated texture does not extend to the white part. The organization may be well ſeen in the hoof of an animal, as the horſe; where the plates are of conſiderable breadth and number.

The edge of this concave adhering portion is fixed in front by the epidermis, which, after covering the extremity of the finger, is attached to the ſurface of the nail at the front end of its laminated portion, in a curved line; here again it ſeems to be confounded with the ſubſtance of the nail.

The looſe anterior portion, the length of which is limited by cutting, is manifeſtly thicker than the middle and poſterior parts. Indeed the thickneſs, hardneſs, and reſiſtance of the organ increaſe gradually from behind forwards.

At the attachment of the nail, the ſkin is marked by a deep parabolical groove, in which the former is received: the fold, which bounds this groove behind, overlaps the white part of the nail, covers a conſiderable portion of it, and adheres firmly to the poſterior thin edge. From this hollow the cutis is produced over the poſterior ſurface of the laſt phalanx to the end of the finger, between the nail and the bone, and adheres cloſely to the perioſteum. At the ſides and in front it is continuous with the common ſkin. In this ſituation it has a peculiar organization; it becomes ſofter and redder, has more numerous veſſels, and is diſtributed in longitudinal laminæ, correſponding to, and received between, thoſe of the nail. But the portion of ſkin correſponding to the white part of the nail, is alſo different in its colour, and not laminated on its ſurface. From this part numerous fine and long papillæ or villi ariſe, and are received into correſponding hollows of the nail: the ſame ſtructure exiſts more or leſs over the whole ſurface covered by the nail. It appears that the organ grows principally from the white part: at leaſt, if a mark be made towards the root, it gradually advances to the looſe edge, coming more and more forwards until it entirely diſappears. The papillæ of this part give to the organ a very exquiſite ſenſibility: hence the acute pain of paronychia, and of that barbarous practice of tearing off the nails.

Organization and Properties of the Nails.—Theſe can be moſt advantageouſly obſerved in the larger ones, as thoſe of the thumb or great toe. A ſingle lamina occupies the whole convex ſurface; this exiſts alone at the poſterior edge, and hence the thinneſs of that part. New plates are ſucceſſively added on the concave ſurface towards the front, ſo that the organ becomes ſucceſſively thicker and thicker: they may be eaſily removed in ſeparate ſtrata, and are ſhorter and ſhorter as they are placed more and more towards the front.

Theſe laminæ, compoſing the nails, ſeem to be in their nature nearly identical with the epidermis. The moſt ſuperficial is manifeſtly continuous with that organ by its edges. The nails may be detached and are regenerated exactly as the cuticle is. Their vitality is as obſcure as that of the cuticle: they exhibit no trace of animal ſenſibility, nor of any organic property. When burnt they cauſe a diſagreeable odour like that of the epidermis, and exhibit altogether the ſame phenomena. Mr. Hatchett conceives that they conſiſt, like the cuticle, of coagulated albumen. They contain a little phoſphate of lime. Maceration and coction do not, however, produce in theſe organs the ſame want of conſiſtence or kind of brittleneſs which they do in the epidermis, on account of their greater ſolidity. The action of acids preſents nearly the ſame phenomena. Thus, on the whole, the compoſition, organization, and properties of the nails and epidermis ſeem to be perfectly analogous: they make up together a perfect inſenſible covering to the cutis, a ſtructure void of vital properties, and therefore exerciſing no vital functions. The only differences between them ſeem to be modifications of form and arrangement ariſing from the uſes of the parts which they cover. Phyſiologiſts aſſign to the nails the office of ſupporting the ſoft ends of the fingers by which the ſenſe of touch is exerciſed, affording to the papillæ a point of reſiſtance, and protecting them from external violence. They are alſo ſuppoſed to enable us to graſp objects more firmly, and to take up minute bodies more conveniently.

Developement of the Nails.—While the ſkin is ſtill pulpy in the fœtus, the nails poſſeſs conſiderable firmneſs, but are very thin. Their length at the time of birth is not proportionate to what they acquire afterwards; they do not exceed, and frequently do not reach the ends of the fingers. At this time their tranſparency enables us to obſerve the livid colour of the venous blood circulating before reſpiration, and to obſerve how it is ſucceeded by the redder arterial fluid. After birth they increaſe as the epidermis does; and they become extremely thick in old perſons.

Of the Hair, (Syſtême Pileux of Bichat.)—The human frame poſſeſſes much leſs of this covering than that of animals: the contact of external bodies with the ſkin being in great meaſure intercepted in the latter, the animal ſenſibility of the cutaneous organ muſt have much fewer external relations in them, and conſequently perform a much leſs important part. In animals the reproductive and digeſtive functions ſeem to be the principal ſources of pleaſure.

1. *Hairs of the Head.*—The ſyſtem predominates in this part, covering the cranium nearly as the bodies of animals are covered. For this reaſon, as well as on account of its convex form, which allows it to come in contact with bodies by a ſmall ſurface only, it is very little capable of acting as an organ of touch. The face is leſs generally covered, excepting one part in the male ſex. This portion of the body, in which moſt of our means of communication with external objects, as the organs of ſight, ſmell, and taſte are aſſembled, is not favourable in its form to the exerciſe of touch. The elongated ſnout of moſt quadrupeds enables them to touch external objects, to turn and move them in various directions, as well as to ſeize them for food: in man the former functions are exerciſed by the hands.

The boundary of the hair towards the front is very variable in different individuals: and theſe varieties influence the breadth and apparent height of the forehead; the direction of this part is dependent entirely on the bony ſtructure. Hence the hair influences but ſlightly the expreſſion of the figure: we attach the ideas of majeſty and grandeur leſs to the breadth of the forehead, than to its perpendicular direction. The number of the hairs in a given ſurface is ſingularly variable: they may be ſo cloſe as to touch in every point, or may leave intervals in which the ſkin of the cranium is viſible. We hardly know the natural extent of their growth. They will ſometimes become ſo long as to touch the thighs or even legs; and this circumſtance, like a crowd of others, tends to prove the deſtination of the human ſubject to the erect attitude. It has been queſtioned whether the practice of cutting them produces any phyſiological effect; whether the conſtant growth, rendered neceſſary by this practice, be performed at the expence of any other parts or functions.

The ſtrength of the hair is very conſiderable in proporto its ſlender bulk: no part in the animal economy, not even the fibrous ſyſtem, will ſupport ſuch conſiderable weights. Ropes made of hair would therefore be very uſeful, if they could be procured of ſufficient length.

Smooth and ſtraight hair grows to the greateſt length; in proportion as it is curly it is ſhorter, of which the woolly kind in the negro is a remarkable example. The colour varies in the different races of mankind, and thus becomes a characteriſtic attribute in the natural hiſtory of the ſpecies. But it varies no leſs in the different individuals of the ſame ſpecies; and theſe varieties follow the ſame general rule with that which regulates the colour of the ſkin and eyes. Hence theſe differences are to be conſidered in enumerating the characters of the different temperaments.

The eyebrows and eyelaſhes are deſcribed under the article EYE. The hair compoſing the beard, which we have alluded to in the article GENERATION, as one of the ſexual diſtinctions of the male, is ſhorter than the covering of the head, and longer than any other hairs in the body: it is always more or leſs diſpoſed to curl, is ſtronger and leſs greaſy than the hairs of the head. It generally follows their colour; but very often deviates into the red tint. Its quantity varies ſingularly in different individuals: common opinion aſſociates the idea of ſtrength to its abundance, particularly if it be black. For ſome remarks on the effects of cutting it, ſee HAIR.

2. *Hairs of the Trunk.*—Their quantity is expoſed to very great variations; ſome being almoſt covered, while others have the ſurface perfectly ſmooth. They are much more numerous in front than behind: and in the former ſituation abound chiefly on the cheſt, and in the courſe of the linea alba in men. There are none on the thorax in women, who have altogether but few on the trunk. A conſiderable collection, reſembling the beard in its nature, is found about the generative organs in both ſexes. Theſe are very ſeldom light in colour, frequently approaching to red, and very commonly black. This increaſe of the hairy ſyſtem is almoſt peculiar to the human ſubject. Its quantity varies very greatly.

3. *Hairs of the Extremities.*—Theſe organs are for the moſt part covered: the number of their hairs is nearly uniform in moſt individuals, but the length differs greatly. In the hollow of the axilla, a ſmall collection occurs reſembling thoſe of the genital organs: but there is nothing like this in the lower limbs. The inner ſurface of the arm and fore-arm has none of this covering in moſt men: but the lower limbs are more uniformly covered; the back of the foot and hand are conſtantly covered, but the palms and ſoles, and correſponding ſurfaces of the fingers and toes, are always perfectly ſmooth. The latter circumſtance ſeems to contribute to the pefection of the organ of touch.

On the organization and mode of growth of the *hair*, the reader is referred to that article.

Properties of the Hair.—It experiences but a ſlight corrugation from the action of heat, but it is twiſted or curled in various directions: moiſture makes it ſtraight again. It hardly poſſeſſes any extenſibility or contractility. Whether they have any vital properties is a ſubject of diſpute: at all events they are exceedingly obſcure. We are diſpoſed to deny their exiſtence in this ſyſtem, as well as in the epidermis and nails. Bichat, who, for ſome of the reaſons explained in the article HAIR, conceives that they are the ſeat of vital proceſſes, adds, "we cannot however deny, that in the natural ſtate theſe organs come next to the epidermis and nails in poſſeſſing the leaſt active life, and having the feweſt relations to other organs. While all other ſyſtems are deranged by diſeaſe, this is generally unaffected; the hair grows as uſual, and ſeems not to experience the ſlighteſt diſturbance; its mode of exiſtence is, therefore, quite different from that of other ſtructures."

Mr. Hatchett concludes, from his experiments, that hair contains gelatine, and owes its ſuppleneſs and toughneſs to that matter. This may be ſeparated by boiling it in water, after which it is much more brittle. If the proceſs be continued for a long time, the hair crumbles in pieces between the fingers. The portion inſoluble in water poſſeſſes the properties of coagulated albumen. Vauquelin obtained a ſolution of human hair in water, by raiſing the temperature of the fluid in Papin's digeſter. When the heat was too great, it was decompoſed, and ammonia, carbonic acid, and an empyreumatic oil formed. Sulphuretted hydrogen is always evolved, and its quantity increaſes with the heat. The ſolution of hair effected in this way contains a kind of bituminous oil, which is depoſited very ſlowly. The colour of this oil correſponds with that of the hair. Filtration allows a colourleſs fluid, in which copious precipitates are formed by infuſion of galls and oxymuriatic acid, to paſs through. Silver is blackened by it, and acetate of lead precipitated brown. Though very much concentrated by evaporation, it does not concrete into a jelly. Water, containing four *per cent.* of potaſh, diſſolves hair with an evolution of hydroſulphuret of ammonia. A thick oil, differing in colour according to that of the hair, with ſome ſulphur and iron, remains undiſſolved. Sulphuric, muriatic, and nitric acids diſſolve it: with the latter an oil is ſeparated. Oxymuriatic whitens, and then reduces it to a ſubſtance of the conſiſtence of turpentine. Alcohol, digeſted on hair, extracts from it two kinds of oil: the firſt is white, and ſubſides in white ſhining ſcales as the liquor cools; the ſecond varies according to the hair employed: it is greyiſh-green when black hair is uſed, and as red as blood when red is employed. When incinerated it yields iron and manganeſe, phoſphate, ſulphate and carbonate of lime, muriate of ſoda, and a conſiderable portion of ſilica. The aſhes of red hair contain leſs iron and manganeſe; thoſe of white hair ſtill leſs, but they contain magneſia. The aſhes do not exceed 0.015 of the hair. According to the above experiments, performed by Vauquelin, black hair is compoſed of the nine following ſubſtances; 1, an animal matter, which conſtitutes the greateſt part; 2, a white ſolid oil, in ſmall quantity; 3, a greyiſh-green oil in greater abundance; 4, iron in an unknown ſtate; 5, oxyd of manganeſe; 6, phoſphate of lime; 7, carbonate of lime, in very ſmall quantity; 8, ſilica; and 9, ſulphur. Thomſon's Syſtem of Chemiſtry, book v. chap. 2. ſect. 7.

Developement of the Hair.—In the firſt months none can be perceived. When the fibrous part of the cutis begins to be perceptible, we ſee a ſlight down on the head, concealed, in great meaſure, by the white unctuous matter. The colourleſs down begins to aſſume ſomething of the tint which the hair will have after birth, but it is in all caſes pale till birth, when it may be half an inch long on the head, although it is only in the ſtate of down in any other part. It grows much more rapidly after birth than before; but is always comparatively lighter in colour in proportion as the ſubject is younger. The age of puberty witneſſes a remarkable change in this ſyſtem in the developement of the beard, of the hair about the organs of generation, and in the axillæ. It undergoes very little change in the following years; but is ſaid to grow more rapidly in ſummer than in winter. Towards the end of life the hairs feel that general obliteration which affects all the exterior veſſels: it ceaſes to receive colouring matter, and becomes grey. On the ſubject of this change, ſee Hair. After remaining grey for ſome time they fall off, and the bulbs ſhrink and diſappear. Bichat found no traces of the latter parts in the integuments of perfectly bald old men: but they were entire in the caſe of a man who had loſt his hair from a putrid fever.

It has been very generally ſuppoſed that the hair, nails, and epidermis continue to grow after death: but we have no very accurate obſervations on this ſubject. Bichat ſaw the fact in a cloſely ſhaven head macerated for eight days: and there is no greater difficulty in admitting this than in allowing that the abſorbing veſſels can continue their action at the ſame time. The growth of the hair does not ſeem to go on at a rate proportioned to the degree of living power: it is as rapid in caſes of proſtration as in thoſe where theſe forces are augmented.

Bichat, Anatomie Generale, tom. 4. Haller, Elementa Phyſiologiæ, lib. 12. Cruikſhank on the Inſenſible Perſpiration.

Integument is alſo extended to the particular membranes which inveſt certain parts of the body; as the coats or tunics of the eye.

INTELLECT, a term uſed among philoſophers, to ſignify that faculty of the ſoul uſually called the *underſtanding*.

The Peripatetics make two kinds of intellect; *active* and *paſſive*. See Idea.

INTELLECTUAL Education, is that branch of education which reſpects the underſtanding, conſidered in diſtinction from the affections and diſpoſitions. By intellectual education we underſtand that ſeries of means by which the various powers, which may be called the intellectual powers, are cultivated; by which thoſe habitual qualities of mind are produced, which immediately reſpect the acquiſition of knowledge, or are eſſentially auxiliary to it; and by which the mind is ſtored with thoſe ideas which are ſubſervient to ſcientific acquirements, or to the arts and purſuits of life.

The full conſideration of theſe objects would lead to three primary diviſions of this branch of education: firſt, the cultivation of the ſeveral intellectual powers and qualities; ſecondly, the value and mode of cultivation of the different branches of knowledge; and thirdly, the peculiar culture of mind and intellectual acquiſitions requiſite for the different ſexes, claſſes, and profeſſions. In a field ſo wide, it is neceſſary to make ſome ſelection. In our preſent article we ſhall chiefly confine ourſelves to a brief conſideration of the culture of the leading intellectual powers and qualities. The laſt of the three diviſions (which will include ſome remarks claſſing under the ſecond), would in ſome meaſure lead us to anticipate what more properly comes under the head of Moral *Education*; and we ſhall therefore leave the conſideration of it to that article, for which alſo we ſhall, for the ſame reaſon, defer a comparative view of the advantages of public and private education.

Though it is not our buſineſs, in this department, to enter into the ſubject of mental philoſophy, yet, as in a work ſo extenſive as the preſent, the ſame arrangement, views, and employment of terms cannot be expected throughout, we ſhall find it at leaſt expedient to ſay more reſpecting the ſeveral powers of the mind than might be in any way requiſite, if we were poſſeſſed of what will be brought forwards in a more direct form, under its appropriate head: independently of which conſideration, we ſhould be induced to give ſuch general views of the intellectual powers as are neceſſary, in order to underſtand the principles of education, by the hope that thus we might be the means of exciting the attention of ſome of our readers to a branch of knowledge which is of peculiar importance, not only in the education of others, but in the cultivation of our own minds.

The firſt of the intellectual powers in the order of developement is of courſe ſenſation (or leſs ambiguouſly the ſenſitive power); by which is meant that power or capacity of the mind, by whoſe operation it receives ſenſations from things which affect the organs of ſenſe. Proceeding in the ſame order, we next find the retentive power, without which ſenſations would be of no avail: this is the power or capacity of the mind, by which it retains relicts of ſenſations or ideas. Next ſucceeds the aſſociative power, which is that power or capacity of the mind by which it connects and compounds ideas. This laſt principle, if not the ſole cauſe of all our mental phenomena (except the origin of ſenſations, and the retention of the ſimple uncompounded relicts of them), has ſome effect in the origin and modification of all of them. It is owing to this important principle that ſenſations become the ſigns of thoughts and feelings, by which means man becomes a ſocial being; that the whole mental furniture of perceptions, notions, affections, paſſions, ſentiments, emotions, &c. is formed from the ſimple relicts of ſenſation; that man, from mere ſenſation, riſes to intellect. In ſhort, whatever mental operation we attend to, except at the very earlieſt period of mental culture, we find aſſociation the cauſe of its productions, or intimately concerned in it.

Theſe three powers may be conſidered as the elementary powers of the mind, to the operation of which all intellectual phenomena may be referred; but as it is under peculiar modifications and combinations that we ſee them act, this ſummary diviſion would be inſufficient for our purpoſe. We ſhall therefore follow in the order which we find moſt convenient, a ſomewhat more minute diviſion of our intellectual principles, according to the combinations, or peculiar modes of operation, of the ſimple powers; *viz.* ſenſation, perception, obſervation, attention, abſtraction conſidered both as a habit and as a power, memory, underſtanding, and imagination.

1. *Senſations* are the rudiments or elements of all our ideas, that is, of all our thoughts and feelings. When an infant enters into the world, there is no appearance whatever which can authorize any one to aſſert that there are ideas in its mind; and no one can reaſonably doubt, that if a human being could be deprived of all his organs of ſenſation, before any ſenſations had been received, that he could never have ideas. In the earlieſt exerciſe of the capacity of ſenſation, ſenſations are ſimple, uncompounded with the relicts of former correſponding ſenſations; but the ſenſations very ſoon become perceptions, that is, they inſtantaneouſly recal the relicts of other correſponding ſenſations. That ſenſa-

tions, in a ſomewhat advanced ſtate of mental culture, are uſually perceptions, any perſon may ſatisfy himſelf, by conſidering that ſenſations are uſually accompanied either with an idea of an external object cauſing them, or (if they are merely the effect of the ſtate of the bodily ſyſtem) with an idea of the ſenſation being in that part of the body, in which the cauſe of the ſenſation exiſts ; both of which are complex ideas, formed from a great number of impreſſions, and which could in no inſtance be produced by any exertion of the ſenſitive power alone, but neceſſarily require the exerciſe of the retentive and aſſociative powers.

Conſidering man as an intellectual being, the correctneſs and extent of his perceptions are of the firſt moment. They are, in fact, the materials of all knowledge reſpecting external objects ; and in the early ſtages of mental culture are the only objects of the underſtanding. Now, the correctneſs and extent of the perception depend upon the vividneſs and efficaciouſneſs of the component ſenſations, and the number of them received from the ſame or ſimilar objects in different ſituations, and through the medium of different ſenſes. One leading object, therefore, in the education of the human being, ſhould be to invigorate and exerciſe the organs of ſenſe. Independently of the effects of the general healthineſs of the ſyſtem, it appears decidedly probable that the organs of ſenſe are capable of being improved by proper exerciſe. It is a grand law of our frame, that moderate exertion increaſes the power of exertion ; and there are facts which lead to the ſame concluſion in this particular caſe. But this may be ſafely left to the natural effect of varied exerciſe. What is principally to be done is, to afford children the opportunity of exerciſing their ſenſes on a variety of objects, and in a variety of ſituations. We ſhould think it deſirable to proceed a little farther on the cultivation of the organs of ſenſation ; but ſome obſervations on this ſubject will properly form a part of what we ſhall have to ſay under the head of PHYSICAL *Education*.

II. By the law of aſſociation, many ideas, received directly from ſenſible objects, through the medium of different ſenſes, become connected, and at laſt blended together, ſo as to form one very complex, though apparently uncompounded, idea; and this complex idea is often recalled to the mind by a correſponding ſenſation ; and by aſſociation it becomes ſo connected with that ſenſation, that the complex idea itſelf is often miſtaken for a part of the ſenſation. For inſtance, the ſenſation produced by the impreſſion made by a globe on the ſenſe of ſight, is, as can be proved, nothing more than that produced by a circle, with certain variations of light and ſhade : yet, immediately on the ſenſation being received, the ideas of the ſolidity of the object, of its hardneſs, of its magnitude, and of its being ſomething external to oneſelf, (all of which have been derived from the ſenſe of touch, in connection with this object, or others in ſome reſpect ſimilar,) immediately riſe up in the mind in one blended form ; by their complete coaleſcence they appear to be one, and by their immediate and conſtant connection with the ſenſation, they appear to the mind as a part of the ſenſation. The ſenſation thus connected with the complex idea is the perception : and by the faculty of perception we underſtand that compound power (or rather combination of powers) by which perceptions are received from external objects. The accuracy and vividneſs of the ſenſation depend upon the ſenſitive power and its organs : the accuracy and vividneſs of the perception depend partly upon the accuracy and vividneſs of the component ſenſations, and partly upon the activity of the retentive and aſſociative powers. Suppoſing the powers of ſenſation to be in a ſound and vigorous ſtate, yet it is obvious that the perceptions will vary very greatly in different individuals, and in the ſame individual, at different periods. The perception is in fact the ſum total of all the notions which the individual has of the object. How much the perceptions of the ſame object vary in different individuals, may be underſtood from a ſimple inſtance. Suppoſe a watch to be ſubjected to the obſervation of three perſons, whoſe organs of ſenſe are alike healthy and vigorous, the one a very ignorant perſon, totally unacquainted with its purpoſes and movements ; the ſecond a well-informed perſon, not however poſſeſſed of any acquaintance with the particular mechaniſm ; the third an artiſt, minutely and completely acquainted with it : the ſenſation may be preciſely the ſame in all inſtances ; the picture upon the retina may convey to the mind an equally impreſſive notice of the object ; but how different the perception ! The firſt ſees a number of minute objects, which attract his attention perhaps by their beauty and regularity ; but nothing more : he has no idea of their ſubſerviency to each other or of their general uſe ; there is little more in his caſe than ſenſation, indeed we may ſay, nothing more than ſenſation beſides thoſe aſſociated perceptions which ſo ſoon become connected with every impreſſion from external objects, and to which we have already referred. The ſecond, from his general knowledge of mechaniſm, has ſome ideas excited by the ſenſation of uſe and connection, but he cannot diſcern the ſpecific kind of connection, nor how each part tends to anſwer the end of the whole. If he ſets about to ſtudy the mechaniſm, he ſubjects each part to minute examination in its ſtructure and connections ; and by degrees may acquire an acquaintance with the whole, which, on a ſubſequent inſpection, would give him an immediate, diſtinct perception of the parts and purpoſes. What he thus acquires by laborious and patient examination, the third ſaw at once. His perceptions have long been cultivated by daily attention to the movements and their dependencies, by ſtudying their defects and excellencies, by the actual formation of various parts, and the conſtruction of the whole : and a great number of the ideas produced by ſuch obſervations and operations, become ſo intimately united with the ſenſation, that at laſt this at once excites them, and thus he ſees (or, more correctly, perceives) what lies totally out of the reach of the obſervation of others.

From this brief account of the perceptive power, we may readily derive the moſt eſſential conſiderations as to its cultivation. To render the ſenſations efficacious in forming diſtinct ideas, and to connect theſe ideas already derived from any object with the new impreſſions, depends principally upon the degree of attention (or fixed direction of the mind) which the ſenſations receive. Hence thoſe who have the care of infants and young children, ſhould give them every opportunity to keep their attention directed to the objects of their ſenſes ; and every means ſhould be employed to lead them to ſuch attention. An infant, intently gazing upon an object, or examining it with its little hands and lips, is as uſefully employed in the cultivation of intellect as the fondeſt parent can wiſh. In the early periods of mental culture there is, however, more to be done in this connection by allowing a child full ſcope for its own efforts, than by any direct exertions which can be made by others. When its attention is fixed upon any object, let it remain ſo ; if poſſible let the objects of ſenſe be brought into view under different aſpects, and expoſed to the examination of different ſenſes. Before words become to a child the ſigns of voluntary action, all that can be done is to expoſe it to ſenſations, and to allow them to fix the attention; but afterwards more direct efforts may be made, and the attention may be fixed by various other means beſide the mere action of the ſenſations themſelves.

Children of quick ſenſations, for the proper cultivation of the perception, require to be frequently induced to obſerve minutely the objects of perception. We do not venture to go ſo far as to aſſert, that it is of no conſequence what they obſerve, provided that they do carefully obſerve it; but there can be no heſitation in ſaying, that when the ſenſations are conſtitutionally vivid, every inſtance of cloſe obſervation given to objects which are within the ſcope of the comprehenſion, is cultivating the perception, and contributing to the ſtock of materials on which the higheſt efforts of the underſtanding are to be exerciſed: and however trifling, in common eſtimation, thoſe objects may be, yet the mind is receiving a uſeful employment, and every thing is going on as effectually as could be wiſhed. It is a moſt erroneous idea in education, that nothing is done except when children are engaged in the uſual rudiments of inſtruction. A child watching the motions of objects around, obſerving their figure and ſounds, examining their ſtructure, is employed in a work which it ſhould be our aim as much as poſſible to aid and encourage, and from which we may expect very valuable reſults both on the faculties and furniture of the mind.

The leading point with reſpect to thoſe whoſe phyſical ſenſibilities are lively, is to engage them to ſteady obſervation of the objects of perception; with reſpect to thoſe whoſe ſenſations are by their conſtitution dull, our efforts muſt be directed to the awakening of the perceptive power. Whatever is found to ſtimulate the mind to the exerciſe of the power, muſt there be employed. It does not much ſignify in this caſe whether, in the firſt inſtance, we ſucceed in producing ideas which will be permanently uſeful; if the perception is exerciſed, it will become more vigorous, and by degrees the original dulneſs of ſenſation may be in ſome meaſure remedied, by the influence of aſſociated feelings. But, in general, dulneſs of perception does not ariſe from dulneſs, and ſtill leſs from deficiency, in ſenſation; but from the inefficient employment of the organs of ſenſe. Many lively children are found to be dull in their perceptions; and on the other hand, children whoſe phyſical ſenſibilities are far from vivid, ſee what their companions ſee not, and hear what they hear not: the former glance over, and ſee at a glance, the moſt impreſſive objects, or features of an object, but the more minute parts, or the leſs prominent, and brilliant objects, they do not ſtay to notice, and though theſe affect the organs of ſenſe, they make no impreſſion on the mind; the latter more readily dwell on the objects of their ſenſations, which allows the various parts to call up aſſociated ideas, and in other ways to affect the mind, and thus to make their ſenſations efficacious.

III. The habit of accurate *obſervation* depends, in a great degree for its foundation, upon the manner in which the perceptive power has been early cultivated, while at the ſame time it invigorates the perceptions: indeed, in ſome points of view, it may be regarded ſimply as the employment of the perceptive power. This habit depends alſo, eſpecially for its utility, upon the cultivation of the judgment, and upon the aſſociations which become connected with the objects of ſenſe. A child obſerves, in the firſt inſtance, becauſe the notice of the mind is excited by the pleaſure or pain accompanying the ſenſation; afterwards alſo, through the influence of external motives, that is, aſſociated pleaſures or pains. When the underſtanding is ſo far developed as to perceive the uſes of different objects, this again increaſes the motives to obſervation, and makes it ſubſervient to much valuable cultivation of the intellect. Every fact which is intelligible and intereſting to a child reſpecting the objects of perception, excites the notice of the mind to thoſe objects, at the ſame time that the communication, reception of it in the mind, and repetition of the *ideas*, increaſes the ſtock of knowledge, and exerciſes the memory and judgment, and often the reaſoning powers.

Yet here, as in every branch of education, by aiming to do too much, we may make our beſt directed exertions ineffectual. To obſerve with effect, requires patient and frequently repeated attention. To obſerve is not merely to ſee, but to ſee ſo as to perceive *that*, whatever it be, of which the ever active principle of aſſociation has made the viſual ſenſation the ſymbol or index; and the more the obſervation is well employed, the more will be brought into the view of the mind by thoſe ſenſations which to another would not lead on one link in the chain of thought. To force the obſervation is therefore impoſſible. We may make our children parrots, by giving them words; but the growth of ideas muſt be gradual. The obſervation muſt firſt be employed upon directly ſenſible qualities alone; the more theſe are noticed, and the ideas of them aſſociated together, (in other words, the clearer the perceptions,) the better foundation is laid for future knowledge. By degrees, and as it is perceived that the mind will bear it, thoſe circumſtances and qualities which imply ſome of the ſimpleſt exerciſes of the underſtanding, ſhould be brought into view; and from theſe the ſkilful inſtructor (or rather inſtructreſs, for we preſume that in general the early intellectual education is chiefly conducted, as it will be beſt conducted, by the female ſex) will proceed to others which are ſtill more remote from mere ſenſation. It will uſually be found that children who have been educated in the country, or have had continual opportunities of being in fields and gardens, (other things being equal,) acquire much more completely the habit of obſervation than thoſe who have been bred up in large towns. In the works of nature there is much more than in the works of art to excite the obſervation of children, much more in general than can be made the ſubjects of pleaſing inſtruction; but the judicious parent will not be at a loſs to find numerous objects within-doors to excite the obſervation and exerciſe the perceptive powers; and provided that the obſervation is actively employed, and correct perceptions are acquired, the mental culture in this eſſential point is ſucceſsfully going on.

The habit of obſervation depends in part upon the general culture of the mind, eſpecially upon the aſſociated thoughts and feelings connected with external objects. The poor plough-boy, with all the advantages that his ruſtic employments afford him for the excitement of his obſervation, will often be found extremely deficient in that habit; his perceptions are dull, and his mind is ſcarcely awakened. Senſations often repeated, without any aſſociations being formed with them, ceaſe to excite the notice of the mind; and where the work of inſtruction has been totally neglected, as unhappily it ſo often is among the poor in country ſituations, the noble powers of the mind lie dormant; there is nothing to rouſe its capabilities ſeparate from the narrow round of the daily employments; theſe ſoon become mechanical and ceaſe to excite its exertion; and as far as intellect is concerned, the ſituation is ſurely leſs favourable than that of the untutored ſavage, whoſe ingenuity and obſervation are ſtimulated by the neceſſities of life.—As the mind, therefore, is capable of receiving them, ſuch ideas ſhould be communicated in connection with the objects of ſenſation as are calculated to keep up the intereſt which the mere ſenſations at firſt excite ; and thus to continue that attention to them which may gradually render the obſervation habitual.

It will not be ſuppoſed that we would wiſh the obſervation to be cultivated, to the excluſion of reflection ; the two habits of mind are not in any reſpect in oppoſition, in the early periods of education ; but, on the contrary, the one materially aids the other. The reflection may be well and ſucceſsfully exerciſed upon the ideas which have been left by the abſent objects of ſenſe ; and indeed it is only upon theſe that, at firſt, it can be properly exerciſed. If this be done, the intereſt by which the obſervation is ſtimulated will be kept up ; and, what is not leſs important, the employment of the obſervation will be rendered effectual, and will afford materials for after-reflection. The exerciſe of thought reſpecting the occurrences of the day, reſpecting thoſe things which have been the ſubject of direct obſervation, in ſhort reſpecting any object of ſenſation, is in various points of view of great value ; and the more this is employed, the more the mind is prepared for farther obſervation.

Nevertheleſs, the period of childhood is more the period of obſervation than of reflection (or ſteady attention to our own thoughts and feelings) ; and it is the former that, in the preparatory parts of education, we ſhould make the primary object. It is of eſſential value in every branch of education, and in every department of life. The ſucceſsful acquiſition of every ſcience depending upon experiment ; indeed the acquiſition of knowledge of every kind which depends upon the exerciſe of the perceptive power, the cultivation of the taſte, the common concerns of life, the intercourſes of civility, and the efforts of benevolence, require the conſtant exerciſe of the habit of obſervation ; and ſo long as the obſervation of a child does not reſt merely with the immediate objects of perception, but continues to connect with them that information which the inſtructor communicates, or which has been derived from paſt obſervation, it is very uſefully employed. Whatever method is found to invigorate and correct the obſervation, ſhould be frequently made uſe of ; till the underſtanding has made conſiderable progreſs, this ſhould be a leading object in the intellectual culture ; and in every period of it, the habit ſhould be frequently brought into exerciſe. By a proper cultivation of it, the memory and judgment are directly cultivated ; and while it ſtrengthens and rouſes the energy of the mind, it furniſhes it with ſome of the moſt ſerviceable materials for the underſtanding and imagination.

Thoſe who have been at all engaged in the buſineſs of education, well know in what different degrees accuracy and quickneſs of obſervation are found, and how important it is for the progreſs in intellectual acquirements, and often for the moral culture, that the habit ſhould be early and ſteadily cultivated : and we here wiſh to expreſs our decided opinion, that the character of the intellect and affections, however much it may be modified by future cultivation, receives its ſtamp from the employment of the firſt few years of life ; that the education of the nurſery is of almoſt incalculable moment in the mental and moral culture ; that by the neglect of it, years of labour may be rendered requiſite to compenſate in ſome degree for it ; and that by a proper attention to it, a foundation is laid for a clear and vigorous underſtanding, and lively and pure affections.

IV. *Attention* is an eſſential conſtituent part of the habit of obſervation, and is neceſſary to every obſervation of the mind in its firſt ſtage. Many corporeal, and even mental operations may, when become thoroughly habitual, go on without exciting the attention of the mind : and this we have no heſitation in ſaying, notwithſtanding the great authority of Dugald Stewart to the contrary : but this is not the place for the diſcuſſion of this point ; and what more immediately concerns our purpoſe is, that before any operation of mind is become habitual, the exerciſe of it requires the direct notice of the mind, that attention is requiſite to render ſenſations efficacious, that every exerciſe of the underſtanding requires it, and that the habitual power of employing it in the direction which the judgment points out, may be regarded as what is moſt neceſſary for the attainment of the higheſt degrees of intellectual culture. In this perfect ſtate it is very rarely to be met with ; but in a conſiderable degree it is frequently acquired ; and ſome good portion of it is ſo important in every ſtage of the mental progreſs, that the formation of the habit cannot be begun too early, nor the cultivation of it made too ſteady an object.

Attention is now not unfrequently ſpoken of as a diſtinct faculty of the mind ; and the philoſopher to whom we referred in the preceding paragraph has greatly contributed to this change of nomenclature, if he did not begin it. It may perhaps be regarded as a mere verbal diſtinction if we deny it the appellation ; but, in fact, it appears to be, in its ſimple ſtate, merely the notice of the mind, which in various inſtances is involuntary, but which by degrees may be connected with volition, and directed by habitual tendency, or direct motives, even in oppoſition to the ſtrongeſt impreſſions from external objects. We may very correctly ſpeak of the power of the mind over its attention, and, by abbreviation, of the power of attention ; but the true point of view in which the attention is to be regarded, both when it can be fixed by ſtimuli of different kinds without the direct intervention of volition, and when it is capable of being produced by direct volition, is as a ſtate or habit, which we would in the one caſe ſpeak of ſimply as a ſtate or habit of attention, in the other as the habit of voluntary attention. In very young children the attention is entirely involuntary ; the ſenſible excitements of various kinds which we employ attract the notice of the mind ; and the attention is directed to the moſt impreſſive excitement. This is very much the caſe in every ſtage of education ; but under judicious management the ſtate of mind which we call attention may be early produced by the influence of motives without ſenſible ſtimulus ; and the foundation is then begun for the habit of voluntary attention.

The attention produced by ſenſible ſtimulus begins even with the very firſt ſenſation which is received. It is a beautiful proviſion of Providence, that ſenſations which give pain, while they are the moſt impreſſive, are of rare occurrence ; and that thoſe which are of moſt frequent occurrence, or which it is important for the mind to ſeek for, are attended with pleaſure. It is probable that no ſenſation is at firſt indifferent ; and therefore in the commencement of the growth of intellect, every ſenſation will excite all the attention which is requiſite to give it the degree of efficacy which is neceſſary for the period. All we then have to do, is to allow the attention to remain where the ſenſation calls for it. “ It is unfortunately in the power of a fooliſh nurſe,” ſays Miſs Hamilton, (vol. ii. p. 47.) “ to retard the natural progreſs of the mind, by perpetually interrupting its attention. A child that is much danced about, and much talked to, by a very lively nurſe, has many more ideas than one that is kept by a ſilent and indolent perſon. A nurſe ſhould be able to talk nonſenſe in abundance ; but then ſhe ſhould be able to know when to ſtop.” And the ſame very reſpectable writer adds in a note, from the obſervation of a judicious friend, that nothing more effectually tends to retard the progreſs of the infant faculties than a cuſtom prevalent with nurſes, of keeping the child in a continual trot upon the knees; and this eſpecially in caſes where its attention is moſt cloſely, and therefore moſt uſefully engaged.

But it will not be long before the impreſſions which have often been received ceaſe, by the diminution of their vividneſs, to produce the ſame effect on the mind. When a child has had ſome cultivation of memory and aſſociation, the repetition of a former impreſſion is often much more pleaſant than the firſt reception of a new one; becauſe, if the impreſſion itſelf is leſs lively, and in itſelf conſidered leſs pleaſant, the aſſociated circumſtances often communicate a ſtill more intereſting pleaſure: the child remembers the pleaſure before derived from it; the repetition of it ſets his little faculties to work in connection with his former ſenſation, and the ideas to which it led, and the moderate exerciſe of the faculties is generally pleaſant; and there is often a poſitive pleaſure in the mere repetition of paſt impreſſions, even when the diſpoſition of a child is very active, ariſing from the increaſed power of fully comprehending the objects cauſing the impreſſions. But before the aſſociative power has been much exerciſed, new ſenſations are very commonly more attractive than old ones; and here begins that reſtleſs deſire of novelty, which, while it operates as a moſt powerful ſtimulus to the purſuit of knowledge, requires to be carefully watched in every period of education, leſt the attention ſhould be completely diſſipated, and no knowledge acquired; for there is no principle in education more certain, than that knowledge (clear, correct ideas reſpecting the objects of ſenſe and intellect) cannot be gained by wandering, haſty attention. At this point the efforts of the parent ſhould be given to lead the little mind to the examination and re-examination of the objects of ſenſation; not indeed ſo much by direct influence, as by thoſe little contrivances which a judicious mother ſo ſoon learns by experience, and to aid her in which ſhe may conſult Miſs Edgeworth's excellent obſervations on the ſubject, which, though they more immediately refer to a later period of education, ſuggeſt many important hints reſpecting the beſt methods to be purſued here.

Though we perceive that we ſhall ſwell this diviſion of our article beyond what may be thought its due proportion, yet the ſubject of attention is ſo important, that we ſhall ſelect ſome of Miſs Edgeworth's leading obſervations on the cultivation of the habit, and ſubjoin our own remarks in addition. In doing this we wiſh to lead our readers, if they have not already engaged in it, to the ſtudy of a work, the value of which we rank higher in proportion to our own experience and obſervation, and by no means to prevent it. Though in ſeveral of her poſitions we cannot agree, though we think her work eſſentially deficient, and are by no means ſatisfied as to the probable reſult of her plans on the whole, and though to follow them in detail to any conſiderable extent requires a degree of mental cultivation, and a combination of circumſtances, which are very rare in thoſe walks of life where the ſubject is likely to receive the moſt attention, yet we cannot heſitate in ſtrongly recommending her work, as containing a fund of very important obſervations, the reſult of varied and long-continued experience, guided by ſound judgment and good ſenſe, and generally correct moral views, as exhibiting a number of very important phenomena and principles ſubſervient to mental philoſophy, and as furniſhing to the "practical" parent very valuable aids, even where her plans cannot be minutely followed. Her elementary works ("Early Leſſons," "Parents' Aſſiſtant," &c.) are incomparable; and if their ſtriking and much-to-be-lamented deficiency in every thing like religious principle were ſuitably ſupplied, they would leave ſcarcely a wiſh ungratified. If any female writer ſhould hereafter come forward to the public, poſſeſſing the clearneſs, ſimplicity, correctneſs, and well-ſtored underſtanding of an Edgeworth, the brilliant yet chaſte imagination and "devotional taſte" of a Barbauld, and the energy and high-toned moral principle of a More, diveſted of bigotry, and founded upon genuine Chriſtian theology, in the ſcale of utility ſhe will probably ſtand unrivalled among her contemporaries, however eminent her age may be in every thing great and good. But to return to ſober realities.

The three principles which are laid down by Miſs Edgeworth in her concluding Summary, as of univerſal application, are, that the attention of young people ſhould at firſt be exerciſed for very ſhort periods; that they ſhould never be urged to the point of fatigue; and that pleaſure, eſpecially the pleaſure of ſucceſs, ſhould be aſſociated with the exertions of children. With reſpect to the firſt of theſe points we ſhall extract the following remarks from her chapter on Attention: "Beſides diſtinctneſs and accuracy in the language which we uſe, beſides care to produce but few ideas or terms that are new in our firſt leſſons, we muſt exerciſe attention but during very ſhort periods. In the beginning of every ſcience pupils have much laborious work, we ſhould therefore allow them time; we ſhould repreſs our own impatience when they appear to be ſlow in comprehending reaſons, or in furniſhing analogies. We often expect that thoſe whom we are teaching ſhould know ſome things intuitively, becauſe they may have been ſo long known to us that we forget how we learned them."—"A reaſonable preceptor will not expect from his pupil two efforts of attention at the ſame time; he will not require them at once to learn terms by heart, and to compare the objects which thoſe terms repreſent; he will repeat his terms till they are thoroughly fixed in the memory; he will repeat his reaſoning till the chain of ideas is completely formed. Repetition makes all operations eaſy; even the fatigue of thinking diminiſhes by habit. That we ſhould not increaſe the labour of the mind unſeaſonably, we ſhould watch for the moment when habit has made one leſſon eaſy, and then we may go forwards a new ſtep."

Reſpecting the third point, Miſs Edgeworth urges, that the ſtimuli which we employ to excite attention ſhould be proportioned in degree and duration to the mental character of the individual, and the circumſtances of the caſe. "It is not prudent early to uſe violent or continual ſtimulus, either of a painful or a pleaſurable nature, to excite children to application, becauſe we ſhould, by an intemperate uſe of theſe, weaken the mind, and becauſe we may with a very little patience obtain all we wiſh without theſe expedients." Beſides which, violent motives frequently diſturb and diſſipate the very attention which they attempt to fix. Regularly recurring motives, which intereſt, but do not diſtract the mind, are evidently the beſt. In proportion as the attention becomes habitual, the excitements producing it ſhould be withdrawn. Succeſs is a great pleaſure, and when children have ſometimes taſted it, they will exert their attention merely with the hope of ſucceeding. "Inſtead of increaſing excitements to produce attention, we may vary them, which will have juſt the ſame effect. When ſympathy fails try curioſity; when curioſity fails, try praiſe; when praiſe begins to loſe its effect, try blame; and when you go back again to ſympathy, you will find that after this interval it will have recovered its original power." At the concluſion of her remarks on this head, Miſs E. juſtly urges the cultivation of the affections of children as a moſt important means of acquiring power over their minds, and exciting them to the nobleſt exertions. "When once this generous deſire of affection and eſteem is raiſed in the mind, their exertions ſeem to be univerſal and ſpontaneous: children are then no longer like machines, which require to be wound up regularly to perform certain revolutions; they are animated with a living principle, which directs all that it inſpires."

"With *timid* tempers we ſhould begin with expecting but little from each effort, but whatever is attempted ſhould be certainly within their attainment; ſucceſs will encourage the moſt timid humility. It ſhould be carefully pointed out to diffident children, that attentive patience can do as much as quickneſs of intellect: if they perceive that time makes all the difference between the quick and the ſlow, they will be induced to perſevere."

"It is more difficult to manage with thoſe who have *ſluggiſh*, than with thoſe who have timid attention;" and with reſpect to that claſs of the indolent "who saunter at play and every thing," Miſs Edgeworth does not appear to have diſcovered any remedy. If a child's mind is capable of active exertion in any thing there is hope: the object is to gain the direction of that exertion to the acquiſition of knowledge; but the other caſe ſhe ſeems to conſider as hopeleſs. Locke's propoſal of preſenting them (among other ſtimuli) with fine clothes, eating, &c. ſhe regards as inadequate, but does not ſuggeſt any plan by which the love of knowledge may be produced. We doubt whether inſtances are at all common of ſuch complete want of phyſical ſenſibility as ſhe ſeems to attribute to the ſluggiſh; but "the pain of attention," if it be not excited to ſomething which is beyond the powers of the mind, cannot be ſo great as to render it preferable to undergo ſhame and puniſhment, if judiciouſly adminiſtered. It is probable that a moderate degree of exertion of the faculties is always attended with ſome pleaſure. There are employments which engage the attention, without requiring great effort of mind. The ſimple operations of arithmetic, the copying of paſſages from a printed book, &c. are of this kind. If the performance of ſome of theſe is ſteadily made neceſſary; if temporary abſtinence, for inſtance, or the loſs of every thing which is not neceſſary in diet, be made the regular conſequence of determined ſluggiſhneſs, and the remiſſneſs of attention be conſtantly followed with the trouble of rectifying errors, &c.; in ſhort, if the pain of attention be conſtantly rewarded by the avoidance of ſome greater pain, and the comfort of indolence be conſtantly followed by that greater pain, it cannot be but that in proceſs of time the attention will be leſs irkſome, the mind awakened, and the idea of mental employment accompanied even with ſatisfaction. If once this ſtate is reached, nothing more is wanting, than to make the attention habitual, to employ it gradually on more difficult objects, and as uniformly as poſſible to make remiſſneſs the ſource of inconvenience naturally following from it; and to reward exertion by whatever ſuitable conſequence of it is found to gratify the now awakened mind. The moſt difficult caſe is, where indolence is united with that quiet amiableneſs of diſpoſition, and that tolerable degree of good ſenſe, which, united, make thoſe who do not know how to appreciate the ill effects of the baneful quality, yield their affection and approbation, and give the appearance of injuſtice and harſhneſs to every meaſure of pain or privation which is employed to excite to exertion.

"*Vivacious* children are peculiarly ſuſceptible of blame and praiſe; we have therefore great power over their attachment, if we manage theſe excitements properly. Theſe children ſhould not be praiſed for their happy hits; their firſt glances ſhould not be extolled; on the contrary, they ſhould be rewarded with univerſal approbation when they give proofs of patient induſtry, when they bring any thing to perfection."—"To win the attention of vivacious children, we muſt ſometimes follow them in their zig-zag courſe, and even preſs them to the end of their train of thought. They will be content when they have obtained a full hearing; then they will have leiſure to diſcover that what they were in ſuch haſte to utter was not ſo well worth ſaying as they imagined; that their bright ideas often, when ſteadily examined, fade into abſurdities." With reſpect to children of this character, we think Miſs Edgeworth's remarks peculiarly happy; and from many which we might with advantage ſelect, we will tranſcribe the following: "We ſhould not humour the attention of young people, by teaching them always in the mode which we know ſuits their temper beſt. Vivacious pupils ſhould from time to time be accuſtomed to an exact enumeration of particulars; and we ſhould take opportunities to convince them, that an orderly connection of proofs, and a minute obſervance of apparent trifles, are requiſite to produce the lively deſcriptions, great diſcoveries, and happy inventions, which pupils of this diſpoſition are ever prone to admire with enthuſiaſm. They will learn not to paſs over *old* things, when they perceive that theſe may lead to ſomething *new*; and they will even ſubmit to ſober attention, when they feel that this is neceſſary to the rapidity of genius."

Judicious and uſeful as theſe obſervations are, we are of opinion that Miſs Edgeworth has, in her ſyſtem of education, too much left out of view the actual condition of human nature, that, in every department of life, circumſtances are continually occurring in which it is neceſſary that the attention ſhould be given to objects not in themſelves pleaſant, from their ſubſerviency to others which are of importance, and that exertions, in like manner, muſt often be made, to which nothing but a ſenſe of duty would prompt. With reſpect to the obſervations which we have extracted, they have all their value, and may be applied, with modifications, not only to the earlieſt periods of education, but to every ſucceeding ſtage; yet her plans ſtrike us as deficient. They are principally calculated for thoſe caſes in which, from early example and cultivation, there is a deſire of knowledge excited, in which it is imbibed without direct effort on the part of the parent or early inſtructor, in which, from the habits and purſuits of thoſe around, its advantages are at once felt, and the acquiſition of it regarded as of the firſt importance. In the hands of ſuch teachers as Miſs Edgeworth, ſo well ſuited to the taſk by enlightened judgment, ſteady perſeverance, and the ready command of much varied knowledge, with children whoſe early habits they have themſelves formed, whoſe underſtandings they have cultivated and furniſhed with ideas, the proceſſes which ſhe has pointed out may be all which are ſufficient: but we doubt whether the ends propoſed can, in general, be anſwered by ſuch means alone; and ſtill more, whether they are, in general, calculated to produce that ſtrength and energy of mind which, with a view to an object fixed upon as important, can ſteadily purſue a courſe of arduous exertion.

The habit of attention muſt be gained in order to make any progreſs in intellectual culture; that is of courſe a point decided. It cannot be acquired too early, becauſe thus the utmoſt efficacy will be given to all the other operations of the mind, and eſpecially to the acquiſition of clear, impreſſive, and ſerviceable perceptions; that is alſo a point indiſputable. It muſt, too, be aſſociated with volition as early as poſſible, and then the foundation is laid for every degree of mental culture to which circumſtances may direct.

We are of opinion, that, after this point, Miſs Edgeworth's plans are defective. Her pupils are to be *allured* on too much. The path of knowledge is often a difficult one, and ſometimes requires painful efforts; ſo alſo the path of duty; and the culture to which her ſyſtem is chiefly confined, is ſcarcely calculated to produce that hardy vigour of mind, which, whether the poſſeſſor is called to engage in the higheſt purſuits of ſcience, or in the narrower ſphere of ſocial employment and duties, cannot be otherwiſe than valuable. When the power of voluntary attention is acquired, then the various motives of confidence in the judgment of the teacher, of habitual ſubmiſſion to authority, of affection, and perhaps occaſionally of fear, ſhould be employed as circumſtances direct, in order to give it ſtrength and activity, to excite the pupil to ſuch employment of it as may make it a hardy vigorous principle, capable of employment, even where the employment may have no intrinſic attraction, and may even be at firſt poſitively painful.

If a purſuit can be made attractive to a pupil at the outſet, it is well; but if he have acquired that hardineſs of attention of which we ſpeak, which will enable him to ſtruggle through firſt difficulties, and perhaps by degrees to take ſome delight in them, he is then fitted for the acquiſition of any branch of knowledge to which his objects in life, or the bent of his own inclination and cultivation of his underſtanding, may induce his inſtructor to direct him. If he have not acquired that ſtrength or activity of attention, difficulties which muſt meet him in the higher departments of literature and ſcience, will often be found to ſtop him; and however judiciouſly his attention may have been early cultivated, if it have not acquired this firmneſs, the attractions of leſs arduous purſuits, which will ſtill gratify his taſte for knowledge, will effectually check all progreſs.

There are few points in which the cultivation of the intellectual powers is concerned, in which we do not find the importance of the moral habits, particularly of diffidence, of ſubmiſſion, and the deſire of doing what is right; where theſe are ſuitably produced in the mind by previous education, the culture of the attention very greatly depends upon the inſtructor. The attention may be reſtleſs, or it may be ſluggiſh; but the more ſuitable efforts are made to render it voluntary, the more it comes under the command. Theſe efforts will be made, if the diſpoſitions are right; and when the attention is once become to a conſiderable degree voluntary, the direction of it may be obtained (by the influence of thoſe views and motives, which the above-mentioned moral habits put in the power of the inſtructor,) to whatever object it is thought right to direct it. Thus influenced and directed the way will be comparatively clear. Where the attention is fairly given, the mere employment of the mind becomes itſelf pleaſant. Difficulties will then be overcome, and the pleaſure of ſucceſs will aid every other motive. By degrees the utility of the object begins to be diſtinctly ſeen, and the purpoſes of the different ſteps which are taken to gain it are alſo diſcerned, and then if the habit of patient induſtry have been formed, or the continued direction of the attention be kept up by the influence of the moral habits, the judgment will aid and encourage every exertion, and at the ſame time the foundation of a moſt valuable habit will be laid, of purſuing definite important ends, by the ſteady uſe of ſuitable means.

The habit of attention, or at leaſt the direction of the attention to any object, muſt ſometimes be produced by compulſion, wholly or in part. What kind of compulſion ſhould be employed, and eſpecially whether or not corporeal pain is in any inſtance expedient for this purpoſe, and in other departments of education, will be conſidered under the head of MORAL *Education*: but we here have only to ſtate the fact, that unleſs every impreſſion could be regulated by a judicious parent, from the very birth, compulſion muſt ſometimes be employed, even in the beſt ſymptoms of education,—that education in which compulſion has not been employed, might probably produce amiable characters, but ſeldom ſuch as will be great in intellectual or moral worth,—that as early education has long been, and it is to be feared long will be, too generally conducted without any ſteady cultivation of the habits of induſtry and attention, and of ready ſubmiſſion to authority, the inſtructor to whom children are committed, whether at home or at ſchool, will commonly find ſome degree of compulſion neceſſary, in order to produce that degree of attention which is requiſite for any valuable improvement. With reſpect to this period, and theſe caſes of much neglected mental and moral culture, the chief points appear to be, to proportion the exertion required, as much as poſſible to the degree, not of actual capacity, but of habits poſſeſſed; to abſtract as much as poſſible all cauſes of inattention, and to generate the impreſſion that the effort muſt be made. By whatever means the habit of attention is produced and rendered voluntary, and the more frequently and regularly it is produced by volition, the more it becomes at the command of the will, the eaſier, and conſequently the more pleaſant it becomes, and the more therefore it can be excited when the motives are ſufficiently ſtrong to produce it. It is not, then, "the attention of circumſtances," but the attention of volition: and will then be ſubject in a great meaſure to the judgment, guided by a ſenſe of the importance of the object either in itſelf or to the individual, or to thoſe ſtrong motives which ariſe from the pleaſures of activity, from the gratification of curioſity, the influence of prevailing faſhions, the deſire of obtaining the approbation of thoſe we love, &c.

When the early training of the mind has made its perceptions diſtinct and efficacious, and has given it the habit of ſteady attention, the grand points in intellectual culture are ſecured; and the reſt will proceed, with tolerable care, in the direction which ſound views may dictate.

V. When the attention is directed to ſome particular object of thought, ſo as to prevent its being diverted to any other object of thought, or to any external impreſſion, it is denominated *Abſtraction*. This ſtate of mind has been ſeldom dignified with the name of abſtraction, except when directed to objects out of the common ſphere of thought; but Miſs Edgworth has ſhewn, by her uſual happy method of illuſtration, that it is the ſame habit or exerciſe of mind, whether it be devoted to the higheſt flights of philoſophic purſuit, or to the uſual concerns of life. "Perſons of ordinary abilities," ſhe juſtly remarks, "tradeſmen and ſhopkeepers, in the midſt of the tumult of a public city, in the noiſe of rumbling carts and rattling carriages, amidſt the voice of a multitude of people talking upon various ſubjects, amidſt the provoking interruptions of continual queſtions and anſwers, and in the broad glare of a hot ſun, can command and abſtract their attention, ſo far as to calculate yards, ells, and nails, to caſt up long ſums in addition right to a farthing, and to make multifarious bills with quick and unerring preciſion."

The habit of abſtraction is dependent upon various cauſes; but every perſon to whom the attainment of it is neceſſary, finds it ſuſceptible of culture. It much depends upon the familiarity of the impreſſions which are otherwiſe moſt likely to affect the mind: novel impreſſions from external objects, by their novelty attract the notice of the mind and tend to diſtract the attention: ſenſations which have been long and cloſely connected with trains of thought or feeling, are calculated to divert the attention: objects to which we have been accuſtomed to attend, in like manner ſolicit the notice of the mind from thoſe to which we may otherwiſe wiſh to attend. In ſituations, therefore, where we receive novel ſenſations, unleſs there is a proportionate devotement of the mind to the object of its attention, theſe will at firſt diſtract the attention; and ſo on in the other caſes. Abſtraction depends, too, in part, upon the phyſical ſtate of the ſyſtem. If the nervous ſyſtem is in a ſtrong degree of excitements, external impreſſions proportionally affect the mind, and, of courſe, tend the more to diſtract the attention. Abſtraction is likewiſe ſeriouſly impaired by a general tendency to dwell upon the directly ſelfiſh feelings, whether pleaſurable or painful; becauſe as theſe are conſtantly preſent to the mind, and conſtitute the moſt powerful agents, in their immediate effects, upon the mental ſyſtem, the habitual tendency to give attention to them, puts an almoſt total ſtop to any valuable degree of abſtraction in favour of thoſe objects, which are not immediately connected with ſelf; and this, by the way, furniſhes us with another inſtance of the influence of moral upon intellectual education. This habit alſo depends for its vigour, upon the degree in which the intereſt of the mind can be excited towards an object. With minds of ardour and activity, if the mind be engaged, it is abſtracted from every impreſſion and thought, not immediately connected with the object: and if the intereſt of the mind is ſtrongly excited from any other cauſe, the ſame effect will happen. The vigour of abſtraction alſo, depends, in part, upon the degree in which the habit of obſervation is poſſeſſed; indeed they are ſo much in oppoſition to each other, that to any conſiderable degree they are ſeldom found united in the ſame individual. The habit of obſervation implies habitual attention to the objects of ſenſe; the habit of abſtraction to the objects of intellect. The habit of abſtraction is not therefore to be expected, and indeed ought not to be directly cultivated in the earlieſt periods of intellectual education. Nevertheleſs, both qualities depending upon the general habit of cloſe attention, the cultivation of the obſervation is indirectly laying a good foundation for the ſubſequent cultivation of the abſtraction.

As two objects cannot engroſs the attention of the mind at the ſame time, abſtraction may be cultivated by rendering the mind habitually inattentive to thoſe objects which are not to occupy it, or by making it habitually attentive to thoſe which are from any cauſe the objects of preference. The former plan ſhould be adopted, if at all, with great caution. It may generally be left to the efficacy of habit in leſſening the efficacy of impreſſions; and the habitual neglect of any commonly occurring objects of obſervation or reflection, is inconſiſtent with the purſuits of life. The ſecond plan is in every point of view preferable; and every inſtance in which the attention is fixed, whether through direct volition, or by means of excitement without the exerciſe of volition, is eſſentially contributing to the cultivation of abſtraction; ſtill more ſo, every inſtance in which the attention is engaged upon the objects of thought, in ſituations in which there are frequent impreſſions from external objects which, if the attention were not ſo engaged, would then excite the obſervation. Hence it is deſirable to accuſtom the young to mental exertion where there are cauſes tending to diſtract their attention, provided however that from their novelty or their power they are not calculated to force it. Whatever tends to make the objects of the mind intereſting, and to give ardour in the purſuit of them, alſo tends to cultivate the habit of abſtraction; for that which deeply intereſts the mind, fixes the attention, and of courſe prevents every other object from ſharing the notice of the mind.

The power of directing the mind to objects which afford no impreſſion upon the ſenſes, and even in oppoſition to ſuch as do, is of extreme importance in the later periods of mental culture, and at the ſame time, with the aſſiſtance of previous culture, is much eaſier than would, with any cultivation, be poſſible at an early period. In childhood and youth ſenſations more affect the mind, than the ſenſations themſelves can do as we advance farther in life; and though aſſociated thoughts and feelings aſſiſt to keep up the influence of the ſenſations themſelves, yet if the mind have been accuſtomed early to think of what are not the direct objects of ſenſation, the power of its own thoughts and feelings eaſily overbalances the effect of at leaſt cuſtomary ſenſations. Carried to an undue extent, the habit of abſtraction is unſuitable to our ſituation as ſocial beings; but there is ſcarcely any plan of life in which it is not in ſome meaſure requiſite; and in the purſuits of ſcience, whether phyſical or mental, it is continually required, and continually ſtrengthened by exerciſe. It is even very important in the events of life. The power of directing the attention to ſome ſpecific objects of thought, to the excluſion of others, and to the excluſion of external impreſſions, conſtitutes (as Miſs Edgeworth well obſerves) the leading feature of that quality which we call preſence of mind, and which is ſo often of ſignal ſervice to our welfare, and even to the preſervation of our lives. And this habit is eſſentially requiſite in our moral and religious culture; the acquiſition of religious knowledge conſtantly implies the employment of abſtraction; in the exerciſe of religious affections it is abſolutely neceſſary; and in the diſcharge of duty, in oppoſition to powerful temptations, the power of fixing the attention upon thoſe views and principles which ought to guide us, is of the utmoſt importance.

The habit of abſtraction is in general to be cultivated rather indirectly than directly, in the earlier periods of education; and it is one advantage of the purſuit of knowledge, that it frequently requires fixed attention upon the objects of thought, without aid from the ſenſations. Perhaps it would be beneficial to extend the occaſions for this, in literary and ſcientific education. An eaſy demonſtration carried on without a figure, an operation in arithmetic ſuited to the progreſs of the pupil performed without the aid of the pen or pencil, the deſcription of ſome former object of obſervation, the conſtruing or parſing of ſentences from the claſſics without book, and ſimilar exerciſes of mind, are all calculated to cultivate this habit; and wherever the point can be gained, it greatly increaſes the power of the mind over its attention. Theſe mental operations may uſually be begun early; a child of three or four years of age, can eaſily be brought to make a little addition *in his head;* and while he does ſo, his mind muſt neceſſarily be occupied to the excluſion of other thoughts and of ſenſations. If he thinks cloſely of what he has ſeen, for the time he is exerciſing his abſtraction. If he is led to think on ſome of the ſimple truths of religion, he is exerciſing his abſtraction; indeed theſe conſtitute ſome of the earlieſt and moſt powerful exerciſes of abſtraction. It is very important that theſe and ſimilar mental operations ſhould not be made too frequent, nor continued too long. They ſhould not be continued too long, leſt the fatigue of mind experienced ſhould leſſen the wiſh to think, and in reality check the power over the attention; they ſhould not be made too frequent, becauſe, as we have already obſerved, childhood is the period of obſervation rather than of abſtraction. If the young mind is too much accuſtomed to think about its own thoughts, the imagination will gain too much power, and that habit of inattention to external impreſſions will be formed, which, in moſt caſes, is always injurious, and which in the early period of life is ſufficient to ſtop its progreſs in intellectual improvement. In this, however, as in every branch of education, our efforts ſhould often be regulated by the prevailing mental habits of the individual. A child of lively conceptions ſhould be directed as much as practicable to accurate obſervation; where the conceptions are dull, abſtraction ſhould be encouraged; and it is encouraged by every inſtance in which it is exerciſed with pleaſure, by every inſtance in ſhort, in which the mind is pleaſantly engaged upon the objects of thought without the aſſiſtance of ſenſation, and eſpecially if in oppoſition to ſenſations. Theſe the intelligent parent has greatly at her command; an account of a walk requiring the recollection of little circumſtances and objects which occurred during it, the retracing of ideas on any intereſting ſubject, and various other exerciſes of a ſimilar kind, contribute to cultivate the abſtraction. But after all, it is rather by indirect means, than directly, that we are in the early periods of intellectual culture, to aim to produce and exerciſe this habit. By early giving a decided bias for intellectual purſuits, and exciting a lively intereſt in them, and by forming the habit of ſteady attention to the objects of knowledge as they are preſented to the mind, we do in reality prepare it for the cultivation of the habit of abſtraction, whenever it may be called for by the higher purſuits of knowledge.

Abſence of mind ſometimes ariſes from the mind's being fully occupied with its own trains of thought, but it ſhould not be confounded with abſtraction. The latter implies, at leaſt in the commencement of the particular exerciſe of it, a voluntary direction of the mind: the former, even where it is really cauſed by mental operations, commonly ſuppoſes a want of power over the attention; but it very often ariſes from a more ſluggiſh inattention to external impreſſions. Abſence of mind, proceeding from this laſt cauſe, ſhould be ſteadily and conſtantly checked; not ſo much, however, directly, as by rouſing the attention to the objects of ſenſation, by making the neglect of them unpleaſant, &c.: and it ſhould by every means be diſcouraged in the early periods of education, becauſe it will by degrees induce a tendency to reverie which muſt almoſt inevitably give the imagination undue power, and which is more than any quality of mind calculated to deſtroy all the valuable effects of the habit of well regulated abſtraction. In the external appearances, abſence of mind proceeding from reverie, differs little, if at all, from the fixed intentional devotement of the mind to ſome object of thought; but thoſe who have experienced both, and who have watched their characteriſtics in the young, know that the difference is very important, and deſerving of the careful attention of the early inſtructor. In fact, the habit of reverie is the moſt baneful poſſible to the influence of the mind over its trains of thought; and totally deſtroys, if too much indulged, all power of ſteadily directing the attention to ſpecific objects of mental purſuit.

VI. We have hitherto ſpoken of the *habit* of abſtraction, by which we underſtand (agreeably, we believe, to the common acceptation of the term) the devotement of the attention to ſome objects of thought, to the excluſion of others, and alſo of impreſſions from external objects; but it is well known, that the word is alſo uſed by ſome writers on logic and mental philoſophy, to denote the *power* which the underſtanding has (or rather, is ſuppoſed to have) of ſeparating the combinations which are preſented by it. We introduce the qualifying clauſe, 'is ſuppoſed to have,' becauſe in many caſes the underſtanding has no ſuch power; it is impoſſible, for inſtance, to form a conception of extenſion, without ſome idea of colour, or of length without breadth; but in reality, the *abſtractive power* is, after all, nothing more or leſs, than the power of ſeparate attention, the power of attending to one idea diſtinct from the combination in which it occurs,—of attending to one part of a conception diſtinct from the reſt, and perhaps, by degrees, forming a conception of that part detached from the reſt, of attending to one quality or circumſtance ſeparate from other qualities or circumſtances with which it is really connected, or connected in the mind.

The habit of abſtraction, or fixed attention to the objects of thought, is eſſential to any high degree of mental progreſs, and is requiſite in various circumſtances in life; the power of abſtraction, or of ſeparate attention to ſome object of the mind diſtinct from the combinations in which it is preſented, is neceſſary in almoſt every proceſs of reaſoning, and is the foundation of an accurate, diſcriminating judgment. The power of abſtraction, in this ſenſe, may obviouſly be cultivated without the exerciſe of the habit of abſtraction; except indeed where the object is purely mental. A child attending to one part of a proſpect, to one part of a flower, to one of the ſenſations which an object preſents, (to the colour of a ſubſtance, for inſtance, inſtead of its ſmell or ſhape, or ſize or weight, or to any one of theſe without attending to the colours,) is exerciſing the power of abſtraction; and in theſe very uſeful exerciſes of the power of abſtraction, the habit of abſtraction is not called for; all that is wanting is that of obſervation. On the other hand, the habit of abſtraction may have been cultivated even to exceſs, without the individual poſſeſſing the power of attending to one of a combination of objects, or to a part of a conception, ſo as not to allow the reſt to influence his reaſonings and judgment.

The involuntary exerciſe of the power of abſtraction, is very often produced by the mere influence of the aſſociative power, without any effort on the part of the individual, and ſometimes by the influence of the ſenſations themſelves. Inſtances of the latter continually occur. That impreſſion from any object which is the moſt vivid, attracts the notice of a child; and while the attention is directed to this, the other impreſſions from it remain unnoticed. But the exerciſe of the abſtractive power is often, in a great meaſure, voluntary; and though that degree of this power which ſhall completely ſeparate at once the combinations which are preſented to it, is probably altogether chimerical, yet it is in our power to acquire it to ſuch a degree that the parts which we wiſh to exclude from the attention ſhall not affect our reaſonings, and but little even our feelings. We do not mean that in all caſes we have ſuch power; but the more the mind is trained to it, the more it is to be acquired. And here again we perceive the advantage of the purſuits of literature and ſtill more of ſcience. The abſtractive power is continually brought into exerciſe in moſt of the leading objects of mental occupation. The young are thereby continually led to leave out of view ſome circumſtance or quality, and to direct their attention to the eſſential points. Every definition that is underſtood and made the foundation of reaſoning, every exerciſe of claſſification of words or natural objects according to ſome ſyſtem, brings into play this important faculty. It is neceſſary to every correct judgment, and at the ſame time the cultivation of the judgment ſerves as its guide and brings it into exerciſe.

The abſtractive power ſhould be early exerciſed, but moſt commonly upon the objects of ſenſation. Still however not without caution; becauſe, though ſeparate, ſelect attention is of great conſequence in the later periods of education, yet in the earlier periods, the firſt point is correct and extenſive obſervation in order to lay up a fund of ideas for the future operations of the underſtanding.

With reſpect to the operations of the abſtractive power, as neceſſary in the proceſſes of the imagination, they may be very much left to themſelves. We have no wiſh that the imagination ſhould be ſacrificed; for it is of great importance in the conduct of life, in the purſuits of ſcience, and in ſpiritualizing the mind; but where there is that caſt of mind which will lead to form new combinations from its conceptions; all that is neceſſary is, to give the obſervation frequent opportunities of exerciſe, in various ſituations, upon the objects of ſenſation, that they may be ſeen under different aſpects, and in different combinations. It is in our own power, at any time, to ſee only parts of an object; and by dwelling upon theſe parts, we can form conceptions of them detached from others with which they are connected. Hence, the viſual conceptions are very eaſily ſubjected to the abſtractive power; and as to the objects of hearing and ſmell, they have ſo little neceſſary connection with the objects of ſight, the ſenſations can be received, and the conceptions reproduced, ſo completely independent of viſual impreſſions or conceptions, that there is ſtill leſs difficulty in exerciſing the abſtractive power upon them. Where, therefore, the imagination has any conſiderable ſtrength and activity, the abſtractive power may be expected to be ſufficiently at its command without direct cultivation. Where, however, the imagination is weak or ſluggiſh, it may be adviſable, by leading the attention to ſeparate ſenſations, and to parts of objects diſtinct from the whole, and by directing the obſervation to the ſame objects under different points of view, to cultivate the abſtractive power with ſpecific reference to the conceptions as materials of the imagination. And this ſhould occaſionally be done with a ſtill higher aim, to accuſtom the mind to ſeparate the combinations preſented to it, in order that thoſe haſty, caſual, and erroneous aſſociations may be weakened, which ſo often completely miſlead the judgment, and which, where they do not directly and obviouſly affect it, imperceptibly warp it, and materially increaſe the difficulties which obſtruct the reception of truth.

VII. By the *Memory* we underſtand that power which retains ideas, and which can bring them back again to the view of the mind. The latter act is generally known by the name of recollection; the former, as Mr. Stewart has obſerved, has not yet received any appropriate appellation. It might be called retention; but it appears decidedly preferable to appropriate this appellation to that capacity, or power of the mind, by which relicts of ſenſations are retained, by which, in fact, ſenſations produce ideas.

It is totally unneceſſary that we ſhould dwell upon the importance of this power of the mind. Were it not for the capacity of retaining ideas from ſenſations, man would be a being of mere ſenſation. But without going to this extent, if the retaining power of the memory were greatly impaired, paſt impreſſions, paſt reaſonings, paſt concluſions, paſt experience, would be of no ſervice to the mind in the conduct of life, or in the purſuits of ſcience; and without the power of recalling them to the view of the mind when required by circumſtances, they would in a great meaſure loſe their efficacy and advantage. To make the memory, however, duly ſubſervient to the uſual objects of life, and to the acquiſition of knowledge, it muſt be placed under the regulation of the judgment; and an accurately retentive memory, united with facility of recollection, accompanied with, and guided by, a ſound judgment, may be conſidered as the ſummit of excellence in this branch of the mental faculties.

To enter into the proper diſcipline of the memory, when the individual is ſo far advanced in the cultivation of the underſtanding, as to be able to regulate the culture of his own mind, is not our province: and if it were, we ſhould be able to add little to thoſe very excellent and important remarks which our readers will find in Dugald Stewart's elegant and ſcientific ſection on the culture of the memory. The queſtion which we have to conſider is, what cultivation of the memory is moſt ſuited to thoſe periods which are uſually devoted to education.

We cultivate the memory indirectly by every inſtance in which the attention is directed to the objects of ſenſation; for the vigour and correctneſs of the memory, ſo far as it reſpects external objects, muſt greatly depend upon the accuracy of the perception. In ſome points of view it may be conſidered as the only object at which we need aim with reſpect to the memory in the earlieſt periods of education; for where the ſenſations are duly made the objects of attention, the ſtructure of every mind probably is ſuch, that ideas will be received from them; and the firſt point is, to gain ideas, which may become the rudiments of perceptions, conceptions, notions, and feelings.

The mere formation of ideas from ſenſation, is, however, ſeldom referred to the memory; and though this is a moſt important object, and ſerves as the baſis for every future operation of the mind, it is ſo cloſely connected with the act of ſenſation, that it can ſcarcely be diſtinguiſhed from it. In all probability every impreſſion and every thought which has the notice of the mind, have ſome effect in modifying or ſtrengthening the correſponding ideas which were previouſly formed, if they do not form new ideas; and often without our obſerving the proceſs: but we do not uſually ſpeak of ſuch retention as an act of memory, confining the operation of this power to caſes in which we can bring again into the view of the mind the objects of obſervation and reflection. If the ideas produced by obſervation or reflection have been ſo much impreſſed upon the mind, that by active or paſſive recollection they can be brought again into its view as they were at firſt produced, the retention and recollection of them are conſidered as operations of the memory.

As the mere retention of ideas without the power of recalling them, would be of little conſequence, and as the recollection of ideas ſerves greatly to ſtrengthen the retention of them, it appears that one leading object of our aim in the early culture of the memory, ſhould be, to produce the habit of ready, diſtinct, and accurate recollection. This muſt of courſe, in the commencement of intellectual culture, be employed merely upon the objects of ſenſation, of which the firſt will be words. When a comparatively ſmall number of words have been acquired, the recollection ſhould occaſionally be exerciſed reſpecting paſt ſenſations; chiefly thoſe of ſight, which are in the firſt inſtance moſt eaſily retained and recalled. By degrees, thoſe which have been received by the ſenſe of hearing, ſhould alſo be made the ſubject of recollection; partly with a view to ſtrengthen the power of recollection, but ſtill more the habit of obſervation, and of attention to thoſe directions which in the early periods of childhood are ſo eſſential to well-being, and ſometimes even to exiſtence. For ſeveral years from birth, it appears to us ſcarcely deſirable to exerciſe the memory much upon a connected ſeries of words; the power of recollecting words is of great importance in a later period of the mental progreſs, but in the earlier, the firſt object is ideas; and young children ſhould ſeldom (if ever) be required to repeat words without having a clear idea of the meaning of them. Such ideas muſt neceſſarily be deficient; but they ſhould be correct as far as they go, and at any rate ſhould be ſuch as the little mind can graſp. If the habit of remembering words, and of recollecting them, without underſtanding them, is once begun, there is afterwards a very great difficulty in cultivating the underſtanding, and in making the memory, what it ought always to be, however important in itſelf, a ſubſervient faculty.

In the early exerciſes of the recollection, we are to be fully ſatisfied with correctneſs, however deficient it may be in fulneſs. Correctneſs (we of courſe do not mean in the repetition of words, but in the recollection of ideas) ſhould always be aimed at. The imagination will not loſe by this; for the correct recollection of conceptions and notions tends to fix them more upon the mind; and theſe are the materials upon which the imagination is to be employed. Moſt certainly the underſtanding will be a gainer; for the object of the underſtanding is truth; and truth cannot be found by that mind which has been trained up to falſehood by early habit of inaccuracy. We have no objection for the little imagination early to work upon the conceptions which have already been treaſured up in the mind, under thoſe limits which continual attention will neceſſarily ſet upon the operations of the imagination; only let a child be habituated, in detailing its inventions, to detail them as ſuch; and when recollecting the paſt objects of obſervation, to give a faithful outline of them, however imperfect it may neceſſarily be. We have known an inſtance in which a child not above four or five years of age, whoſe imagination was lively, and whoſe recollection (and perhaps obſervation alſo) had unhappily not been trained to accuracy, frequently told his friends circumſtances which had no exiſtence except in his own mind, with the regularity, and much of the conſiſtency of real facts, and, probably, by degrees did not know whether he was ſpeaking of the creations of his fancy, or of things which he had actually ſeen and heard. Such caſes muſt excite our regret for the paſt, and our apprehenſion for the future.

Great difficulty often exiſts, eſpecially in the minds of perſons whoſe conceptions are vigorous, and who have not been habitually careful to cultivate accuracy of perception and correctneſs in the relation of recollections, to know whether the trains of ideas preſented by the aſſociative power are to be referred to the memory or to the imagination. Such perſons, ſeizing only the outline of a fact or ſeries of occurrences, owing to habitual inattention to their ſenſations, are, from readineſs of aſſociation, able to fill up the tranſcript, ſo as to make it appear plauſible to themſelves; and by once or twice detailing it without minute regard to accuracy, except in thoſe leading features, they give a degree of vigour to the ideas, and of cloſeneſs to the aſſociation of them, which at laſt leads to the full conviction that the whole is recollected. Caſes of this ſort are very frequent; and they often leave upon the minds of others, the belief that ſuch perſons intentionally depart from truth; whereas the fact ſometimes is, that part of their error ariſes from a deſire to give the whole truth when they have materials for only a portion of it in their minds. However, the fault is one which ſhould be carefully guarded againſt, particularly in the early part of life, by making young perſons of lively imagination habitually attentive to the minute as well as to the leading parts of their impreſſions.

Recollection ſhould often be exerciſed directly; but the main object, after all, is, to acquire the power of bringing forwards our ideas when they are wanting; and it ſhould therefore be often exerciſed indirectly, by leading to it for thoſe various purpoſes of life, in which the young are ſometimes capable of being uſeful, and ſtill more, by encouraging the ſtatement of paſt ideas as they are called up by preſent objects, eſpecially when the connection is natural and of a kind likely to be ſerviceable. This ſpecies of recollection obviouſly depends upon the manner in which the aſſociative power is exerciſed; and in fact it is itſelf an exerciſe of that power, to which the young ſhould be led in every practicable way; in the period of childhood by free communication with their friends on their various purſuits and occupations, and afterwards, in addition to theſe means, by compoſition. Continual opportunities occur in almoſt every department of inſtruction, for the advantageous recollection of related ideas which have been before received; and it is only by their being brought into employment, and aſſociated with other ideas and trains of thought, that they can be expected to be permanently retained in the mind, or, if retained, to be at its command.

The recollection of ideas is greatly aided by the connection of words both with them, and with the original impreſſions; for words being, from the conſtant uſe of language, familiar to perſons of moderate mental culture, even in various combinations, they are eaſily retained, and moſt materially aſſiſt in producing the recurrence of the correſponding ideas. And thus, when a perſon is relating a paſt fact, the ideas in ſome caſes ſuggeſt the words, and in others the words ſuggeſt the ideas. Hence illiterate perſons, other things being equal, do not remember nearly ſo well as others. Hence alſo the importance of teaching the young to remember words as well as things; for in moſt caſes, as words ſerve as the bond of ideas, ideas will be looſe and floating in the mind unleſs connected with words.

After what we have ſaid reſpecting the memory, we ſhall not be miſunderſtood when we ſay, that the cultivation of it ſhould conſtitute a very eſſential object in the early periods of intellectual education. Without a doubt there are original diverſities in the capabilities of the mind; and it ſhould be one grand object in mental culture, to excite thoſe which are weak, and to curb and regulate thoſe which are exceſſive. With reſpect to the memory, ſome young perſons appear to retain words, and even ideas, with a degree of facility which aſtoniſhes and perhaps delights the partial friend, while at the ſame time it furniſhes ſome ground for alarm, leſt that which ought always to be made ſubſervient ſhould have the aſcendancy, and prevent due attention to the cultivation of the judgment and reaſoning powers. Others are ſlow in acquiring, but retain for a long time. Others again are diſtinguiſhed by the readineſs with which they recollect, and the eaſe and aptitude with which they bring forwards what their memory has ſtored up; and if the memory has been judiciouſly employed, and the principles of aſſociation have been ſuch as are advantageous to the judgment, this is all which can be wiſhed for. With reſpect to thoſe who poſſeſs great facility of retention, it ſhould be the aim of the inſtructor to encourage, as much as poſſible, the ſound exerciſe of the judgment, and the long retention and ſuitable recollection of ideas, rather than the eaſy acquiſition of words, even if properly underſtood. Durability of retention depends in a great meaſure upon the manner in which ideas are aſſociated in the mind, and upon the caſt of the ideas which have already been received and retained; but this facility of retention, though depending in part upon exerciſe, ſeems to ariſe in no ſmall degree from corporeal organization. It is valuable only as made the foundation of a good memory: it often leads to neglect thoſe exerciſes of the underſtanding, to which it ſhould only be auxiliary, becauſe they are more difficult; and the conſequence, in innumerable inſtances, has been, that while apparently the mental progreſs is going on very rapidly, the judgment, and the reaſoning powers, are almoſt dormant, and the whole of the mental ſtore of the individual conſiſts in the words, or at moſt the ideas of others, without any real acquiſitions of thought, and even without that new-modelling and arranging of them, which would give a degree of appropriation to the poſſeſſion. We have known an individual arrived almoſt at the age of manhood, who found it ſo much eaſier to learn Euclid's Elements by rote, than to underſtand them, that he actually went through ſeveral of the early propoſitions without any ſuſpicion being excited that he had not fully maſtered them; till on an accidental change in the lettering of the figure, or in the conſtruction itſelf, it was diſcovered that memory, not underſtanding, had been exerciſed throughout. Where, however, facility in retention is not poſſeſſed, though it is by no means the moſt important feature of the memory, yet it ſhould be cultivated, directly by actual exerciſe, but ſtill more by well ſtoring the mind with thoſe really valuable ideas which will ſerve as connecting bonds for new ones. That kind or degree of retention which ariſes from aſſociation, not from original organization, is of the greateſt value; and this may be improved to almoſt any valuable extent, where there is good ſenſe to work upon.

Where the purſuits are directed to the acquiſition of literature and ſcience, there is no danger of a want of objects on which to exerciſe the memory in all its uſual qualities. Indeed the danger principally is, of doing too much; and ſtill more, of cultivating the memory almoſt excluſively. The apprehenſion of this has led many ingenious perſons who have been concerned in education, to do too little. They conſider it is unneceſſary to exerciſe the memory more than they think will be probably uſeful in life, or to burden it with things which, if they ſhould be uſeful, may be eaſily acquired when they are wanting. They ſee the memory often made almoſt the only object of education, facts ſtored up without any judicious link of connection, and words, in themſelves conſidered almoſt unintelligible, and which at any rate convey no ideas to the mind of the learner, committed to memory without explanation; and they go into the oppoſite extreme, and ſuppoſe that the cultivation of the judgment is all which they need attend to. Truth, as in many other inſtances, lies between the extremes. The cultivation of the memory ought, moſt aſſuredly, never to ſuperſede that of the judgment; but, on the contrary, ſhould be kept in ſubordination to it, and be regulated by it: but when it is conſidered how many of the purpoſes of life require accuracy and facility of recollection, how neceſſary the memory is to the purſuits of ſcience and literature, and even to the cultivation and exerciſe of the moral ſenſe, can we doubt that as a ſubſervient faculty, and, with a view to its ſubſerviency, we can ſcarcely cultivate it too much.

Without a doubt, the recollection of ideas is the object of the greateſt conſequence; but as we have already ſtated, the memory ſhould often be exerciſed on *words*, both as an aid to the remembrance of *ideas*, and on account of the great importance of an accurate recollection of words in the uſual, as well as in the more peculiar concerns of life. We ſhall never forget, that, in all probability, the reputed murderers of Steele loſt their lives by the definite article being introduced, we doubt not unintentionally, by the reporter of their words: if they ſaid, "We muſt have had gin there," (not as we believe was ſtated in evidence, "We muſt have had the gin there,") their words, ſo far from being a ſtrong, indeed preponderating argument againſt them, were plainly conſiſtent, and indeed moſt conſiſtent, with their reiterated aſſertions: they were diſcuſſing the teſtimony of the king's evidence; and what they probably ſaid, was deſigned to account to one another for his repreſentations. We are often led to repeat the ſtatements of others; and it very frequently happens that it is not ſufficient to give what we think their ideas. If we can give their words, every one may judge for himſelf as to the import of them: if we give merely our own ideas of their import, we preclude all correction of miſtake, if from our peculiar prepoſſeſſions, or any other circumſtances, we have erred. We have ourſelves known inſtances, and probably our readers can at once recollect others for themſelves, where very ſerious conſequences have followed from perſons detailing their own apprehenſions of the meaning of others, inſtead of what they actually ſaid: and from a regard to truth, and from the conſideration of ſuch painful occurrences, we feel perſuaded that the habit of the correct recollection of words ſhould be early made an object, and ſhould not be loſt ſight of in any part of education.

But beſides the directly mental effect of the correct recollection of words, and the importance of it in the concerns of life, we do not perceive how the neceſſity of it can be doubted in the various employments of a literary and ſcientific education. We have no wiſh that the memory ſhould be burdened with a number of rules and facts which are of no direct ſubſerviency to the objects of rational inſtruction; nor that it ſhould be called upon to acquire the principles of grammar, and ſtill leſs of philoſophy, without the continual exerciſe of the underſtanding: but though the judgment will afford material aid to the memory, even in the rudiments of the languages, and is of indiſpenſable utility to its exerciſe in every department of ſcience, yet the ready and accurate recollection of fundamental rules, of the flexions of words, of elementary principles, definitions, &c. is of ſuch ſignal, and almoſt eſſential, advantage, in the progreſs of education, that we cannot but ſuppoſe, either that thoſe who object ſo much to the frequent exerciſe of the memory on words, would not wiſh to be underſtood to the full extent of their own repreſentations, or otherwiſe, that they labour under a moſt material error, ariſing from ignorance as to what exerciſe of memory even a rational education requires, or from forgetfulneſs of thoſe proceſſes by which they have themſelves made acquiſitions which could not have been made without them.

The exertions of the memory may be claſſed in three diviſions, (as reſpects our preſent conſiderations,) thoſe in which it merely ſupplies materials for the judgment; thoſe in which it furniſhes the reſults of previous exerciſes of the underſtanding, (or at leaſt what have before been the objects of the underſtanding,) and in which the underſtanding ſhould ſtill be concerned; and thoſe in which the proceſſes of the memory are become habitual from conſtant employment, and go on "without our ſtopping to think." The laſt claſs is probably much more extenſive than is generally ſuppoſed; facility in arithmetic, and in the ſubordinate exerciſes in the languages, continually require ſuch an exertion of the memory, and where the memory has not been trained to it, the difficulties in theſe elementary acquiſitions are conſtantly felt. All the power which we wiſh the judgment to exerciſe in ſuch caſe, is a controlling power; to ſuggeſt errors and omiſſions, but not to direct what is right; and if the readineſs and accuracy of memory have not been early cultivated, ſay before the age of twelve or thirteen, it will often prove up-hill work to acquire facility in thoſe branches of knowledge which, from being of practical value, are of very frequent occurrence. One caſe has occurred to our own obſervation, in which the exceſſive fear of making the memory paramount inſtead of ſubordinate, led to ſuch a degree of ſlowneſs in every operation in which the judgment is not principally concerned, that the individual found ten-fold difficulties, where the memory of much younger companions (without blindfolding the judgment) ſuggeſted at once every thing that the circumſtances might require, and will doubtleſs enable them to ſucceed beſt in the uſual employments of life. Of courſe we ſhould prefer the cultivated judgment, with great heſitation of memory, to the moſt fluent memory without judgment: but fluency in memory may be acquired without ſacrificing the judgment; and who would then deſpiſe it? One leading object of the work of inſtruction, in the middle period of it, (perhaps from the age of eight to twelve or farther,) is to give by practice that facility of recollection which, if not acquired before the underſtanding is become ſomewhat mature, will ſeldom be acquired at all; and which, though always to be regarded as a ſubſervient quality, is of almoſt indiſpenſable utility in the concerns of life, and even in the employments and reſearches of ſcience.

The remarks in the laſt paragraph were ſuggeſted by what we are advancing on the memory of words, and chiefly refer to it. Words continually ſtand for many thoughts; and ſhort combinations of them frequently imply trains of reaſoning: but it is often ſufficient, for the purpoſes of education, and indeed all that is deſirable, that the memory ſhould ſuggeſt ſuch combinations, and afford the impreſſion of their accuracy, without the exerciſe of the underſtanding to ſhew the truth of them. Two inſtances will illuſtrate our meaning. The common rule of algebraic multiplication, "Like ſigns give plus, and unlike ſigns give minus," is in itſelf conſidered almoſt without meaning, and underſtood literally involves an abſurdity; and we would never teach it to a boy, without firſt ſhewing him that it is a convenient abridgment of a number of operations in algebraic multiplication, all of which are well-founded: but when he has once ſeen the univerſality of its application, we would then lead him to employ it without heſitation, and even without thought as to its meaning: of courſe, however, recommending that he ſhould never reaſon from it, but reſort to the facts themſelves as the foundation of inferences reſpecting the nature and combinations of algebraic quantities. But to take a more familiar inſtance; in common multiplication, where the multiplier conſiſts of ſeveral digits, we are directed to place the firſt figure of each product under the digit by which we multiply. Nothing can be eaſier, when the effect of multiplication by 10, 100, &c., and the nature of our numeration are well underſtood, than to underſtand the reaſon and meaning of the direction; but we ſhould not wiſh that the pupil ſhould continually revert to this explanation; it is ſufficient if he remember the fact diſtinctly, and at the time when it is wanted; and it would only ſerve to embarraſs, if the rationale were to be conſtantly brought into view.

Leaving out of conſideration all the intercourſes of life, in which the ready recollection of words is often the ſource of ſo much intereſt and delight, there is ſtill another point of view in which we feel the importance of the habit of recollecting words readily and accurately. Ideas fade from the memory much ſooner when they are not connected with words. In ſickneſs, and often in old age, the reaſoning powers become languid; and the vigour of the mind, which would ſupply a ſucceſſion of intereſting thoughts, is loſt under the preſſure of diſeaſe or gradual decay. In ſuch circumſtances the mind dwells upon the preſent impreſſions of pain, or weakneſs, and can ſcarcely raiſe itſelf above them; but if the memory have been well ſtored, in the early part of life, with uſeful and intereſting combinations of words, they will often recur, at ſuch periods, without an effort, and without fatigue, and furniſh objects of thoughts which will ſooth and even cheer. Thoſe who are ſubject to any degree of mental depreſſion, diſabling them from active efforts, to point out a channel for their thoughts, often find ſuch ſuggeſtions of the memory an important relief to them. And we need not ſay to thoſe of our readers who have a religious turn of mind, that theſe remarks are peculiarly applicable to thoſe devotional compoſitions and expreſſions, which, where they have been early and deeply impreſſed on the mind, occur at the call of aſſociation to ſupport, to ſtrengthen, and to comfort; and which, thus ſuggeſted by the memory, have in innumerable inſtances allayed the emotions of paſſion and deſire, or poured balm into the wounded heart.

Whether the memory ſhould ever be exerciſed on words which convey no idea to the mind, we do not venture to determine; but as far as our own experience goes, we ſhould be led to conclude that ſuch a cultivation of the memory can be of little ſervice in a rational memory of words. We have at leaſt obſerved, that where a boy has poſſeſſed great facility in committing to memory paſſages from the claſſics, without finding it neceſſary fully to underſtand them, (ſo that the recital of them went on with little if any aid from the underſtanding, but was effected by the mere dint of verbal recollection,) he has uſually found it much more difficult to remember paſſages from Engliſh writers, in which the meaning is obvious, though the modes of expreſſion are out of the common rounds. It appears to us, therefore, that exerciſes of the memory, in which the memory alone is employed, ſhould ſeldom be reſorted to, ſince it does not tend to produce that recollection of words which is ſubſervient to, and indeed accompanied with a recollection of notions and feelings. The firſt ſtage of recollection ſhould be accompanied with the direct exerciſe of the underſtanding: the formula of words may, by habit, ceaſe explicitly to excite the ideas which on reflection it would convey; but it ſhould not be attended with a feeling of unmeaningneſs or unintelligibility.

The only caſe (ſeparate indeed from the rudiments of language) in which it appears particularly expedient to exerciſe the memory upon words alone, is where, though they have no uſual connection with certain facts or truths, they ſerve, by an artificial connection, to bring thoſe facts or truths to recollection; and even here there is the feeling in the mind that they are merely abbreviated repreſentations of a more full combination of words, which is itſelf at once intelligible. We refer principally to ſuch contrivances as thoſe in Grey's Memoria Technica. Of courſe we would by no means recommend the employment of his method to any thing like the extent which he propoſes; but if it be of importance (as we are perſuaded it is) in the reading of hiſtory, that a few leading dates ſhould be well fixed in the mind, his method will be found of great utility by furniſhing an additional aid to the memory; and the mere tranſlation of his technical words, aſſiſts materially in the permanency of the recollection. Caſes may occur, though not very frequently, in which it will be very ſerviceable to bear in mind with minute exactneſs the latitude and longitude of places; and here alſo, the Memoria Technica may be found of conſiderable ſervice: but for the general purpoſes of geographical knowledge, there can be no doubt that much more benefit will be derived from forming in the mind a clear idea of the relative ſituation of places, by means of a familiar acquaintance with the globe, or even with maps. Little advantage can be expected from the extenſion of this method to aſtronomy, and other branches of phyſical ſcience; but if any circumſtances render it deſirable to retain with accuracy the ſize of the planets, their diſtances from the ſun, &c. or the ſpecific gravity of different bodies, Grey's contrivance will be found a uſeful aid, though we can never recommend the employment of it in ſcience, without a full previous acquaintance with the facts to which it relates, and a frequent explicit reference to them: in ſhort it ſhould always be employed merely to aid the remembrance of knowledge, not to enable the young to prate about objects of which they are really ignorant. It is well known to our mathematical readers that there are formulæ of eminent utility, in the remembrance of which the judgment can have little ſhare, and in which readineſs and accuracy of recollection are the chief objects; for inſtance, Napier's celebrated canons for the ſolution of right-angled ſpherical triangles. Here the ſhort ſentence, "the rectangle of the radius and the ſine of the middle part, is equal to the rectangle of the tangents of the extremes conjunct, or, of the coſines of the extremes disjunct," enables the calculator to ſolve with the greateſt eaſe every caſe of right-angled ſpherical trigonometry: but in the recollection of this comprehenſive canon, the underſtanding affords little, if any aſſiſtance; it is a technical formula, in which there is no opportunity of exerciſing the perception of truth, except by obſerving the truth of every claſs of proportions which may be derived from the application of it; when the truth of theſe has been demonſtrated, all we have to do is to remember the canon. In this and many other inſtances in the mathematical ſciences, a ready and accurate recollection of ſigns of ideas is of great ſervice; and we cannot have heſitation in maintaining, even from ſuch caſes alone, that it is deſirable to train the memory, among other objects, to the recollection of words, always indeed as ſigns of ideas, or abbreviated ſigns of thoſe which are immediately ſigns of ideas, and, as much as circumſtances will allow, with an explicit exerciſe of the underſtanding, but ſtill ſo as to make the exerciſe of the memory in theſe inſtances the primary conſideration. The occaſional utility of the recollection of ſuch abbreviations we have already ſufficiently adverted to; and we will only add one ſpecimen of the advantage even of the abbreviated ſtatement of theſe abbreviations. The formula of Napier is readily ſuggeſted to the mind by the memorial words *Tan con, Cos-Dis;* and when theſe are well fixed in the memory, and connected with the more expanded ſtatement of the canon, it is almoſt impoſſible that the mind ſhould ever be at any loſs in the recollection of the canon itſelf, or at leaſt of the import of it.

In caſes where verbal recollection is found to be an object of importance, the ſimpleſt and moſt correct modes of expreſſion ſhould be employed; and, when they are repeated, it ſhould conſtantly be done without variation in the order or ſelection of words. If we can reſort to the underſtanding to check or ſuggeſt the words, this is not of ſo much conſequence; but wherever the ready recollection of words is deſirable, for purpoſes of diſpatch and accuracy, this precaution will be found of great moment.

We do not mean to charge the later writers on education with being the ſole cauſe of that neglect of the exerciſe of verbal recollection, which, a few years ago, was prevalent and faſhionable at leaſt in domeſtic education, and which made its way into ſchools beyond what experience has ſhewn to be uſeful; but the unqualified language which has been uſed by perſons of intellectual eminence, aimed, perhaps in ſome caſes excluſively, againſt burdening the memory with ſounds unmeaning to the learner, and almoſt uſeleſs if they were underſtood, has in many inſtances been extended to all caſes of exact verbal recollection, and has cauſed great difficulties in the ſubſequent periods of education as well as in the purſuits of life. We think that Miſs Edgeworth ſtands chargeable with contributing to and ſupporting this error, not perhaps directly, but by the low eſtimation in which ſhe teaches us to hold the memory, and by the too unqualified manner of her generally excellent obſervations on the culture of it, and the ſubjection of it to the judgment; and we will not deny that we have been led much farther than we otherwiſe intended, by our opinion as to the impreſſion which many have derived from her chapter on the ſubject. Her own writings ſhew that ſhe herſelf poſſeſſes a judicious memory; but without more attention to the cultivation of the recollection of words than ſhe encourages, we feel perſuaded that few will obtain one ſo ſerviceable. There is in that chapter a great deficiency in preciſion and clearneſs; and it has conſequently been the ſource of much error, or at leaſt countenanced it: and the principle is often obvious, that exertion ſhould be exacted only by being made intereſting. Her concluſion, "that memory is chiefly uſeful as it furniſhes materials for invention," is one of thoſe extraordinary poſitions which can only miſlead perſons who can implicitly bow to authority, and who prefer quiet acquieſcence to the trouble of thinking. It has not unfrequently occurred to us, that it is happy for mankind that the human intellect is not generally to be moulded by theoriſts; and we have no doubt that in the common walks of life great numbers, not abſolutely illiterate, may be found, who, though they poſſeſs a tolerable ſhare of good ſenſe and judgment, never have had the merit of forming one new combination of ideas for themſelves, and who yet, by the aid of memory, guided, we allow, by the underſtanding, contrive to paſs through life with credit and utility. Viewing Miſs Edgeworth's poſition as limited to ſcience and literature, the ſubſerviency of the memory to invention is only one, and that not the moſt important department of its exertions; taken as we find it, without any reſtriction or explanation, the poſition is as unfounded as it is injudicious.

It is difficult, in education, to lay down any generally applicable rules, eſpecially if they require the ſpecification of ages; but we ſhould be inclined to divide the courſe of intellectual education into three periods, the firſt extending to about ſeven or eight; the ſecond to about twelve or thirteen; and the third to the time when direct inſtruction ceaſes. In the firſt, the exerciſes of the memory ſhould be conſtantly and directly ſubſervient to the culture of the underſtanding, and ſhould not be employed but where they can be made intelligible. In this period the chief object is to produce ideas, and to connect them with words, to cultivate the obſervation and the judgment, and to ſtore the memory with ideas without much regard to philoſophical principles of arrangement. Some notion of cauſation, however, begins very early in children; and where it can be brought into exerciſe judiciouſly, there appears no reaſon why it ſhould be neglected; but the common bond of union will be connection in time and place, and it is by theſe links of aſſociation principally that recollection will be firſt produced. In the ſecond period, though the exerciſe and culture of the judgment ſhould go on as ever, and even become a more prominent object of attention, yet the memory of words ſhould now be particularly cultivated. In the third period, the exerciſe of verbal recollection ſhould, we imagine, conſtitute a very ſubordinate object. The primary aim muſt then be, to ſtrengthen the judgment, to exerciſe the operations of reaſoning, to cultivate habits of correct generalization and claſſification; and, as the mind expands, to lay the foundation of that judicious ſelection and arrangement of the objects of the memory, which will make this faculty of the utmoſt utility in every valuable employment of the underſtanding, and indeed make every operation of the memory itſelf an important exerciſe of the judgment.

VIII. We now proceed to a few remarks on the cultivation of the *Underſtanding.* We employ this general term (though in reality it may truly be ſaid to comprehend all the preceding intellectual habits or faculties, principally with a view to thoſe operations, which are uſually referred to the heads of judgment and reaſoning, and to thoſe operations of the aſſociative power by which ideas are combined and aſſociated with words.

The foundation of an accurate, diſcriminating judgment, can only be laid in the acquiſition of clear perceptions. During the period of infancy (that is, before the uſe of words is underſtood), this is almoſt the ſole object of intellectual education; and where this is properly attended to, unleſs in very unfavourable circumſtances, the developement of the underſtanding will afterwards go on with ſucceſs. Where this has been neglected, the injurious effects are ſeldom completely remedied. The acquiſition of clear perceptions does not, however, neceſſarily introduce the operations of compariſon, diſcrimination, and judgment ; but when theſe are exerciſed, the perception is thereby rendered more acute and active. The perceptive powers are neceſſarily improved in proportion to the attention of the mind to the objects of perception ; and whatever excites the operations of the mind, is productive of that pleaſure which attends every natural and gentle exerciſe of the mental faculties, more or leſs in every period of life, but particularly in thoſe to which education is chiefly directed. Every ſuch exerciſe of the mental faculties in connection with the objects of perception, tends to excite the attention to thoſe objects, and conſequently to improve the perception. And thus it is, as in every period of the intellectual culture, that the proper exerciſe of one faculty tends to the general improvement of the mind. But to compare, to diſcriminate, and to judge, does not neceſſarily follow from the exerciſe of the perception. In the more complicated perceptions, numerous judgments are often included ; but for the formation of thoſe ſimple ones which are the firſt exerciſe of the mind, nothing more is requiſite than retention of ideas, and that elementary exerciſe of the aſſociative power by which two or more ideas, derived from the ſame or ſimilar objects, are connected with the appearance, &c. of the object, ſo as to be at once recalled by it, and by degrees combined with it : nevertheleſs, where the mind is active, and ſuitable opportunities are given, it very early begins to employ thoſe faculties of the mind on the notions preſented by the ſenſes. We have obſerved, even at the age of twelve months, inſtances of the moſt decided nature, proving the attentive examination and accurate diſcrimination of the objects of ſenſation. Among others, we recal to mind a little circumſtance which we obſerved with great ſatisfaction, where parental partiality was not concerned. A boy, of a fine intelligent caſt of countenance, but not at all able to ſpeak, had a ſtrawberry with its ſtalk on, and a red garden daiſy not fully opened, and which very much reſembled the ſtrawberry, placed before him. He had ſeveral times before eaten ſtrawberries, and of courſe had an infantine motive for diſcrimination. He looked firſt at one, and then at the other ; at laſt he took up the daiſy, but without putting it to his noſe or mouth, he continued obſerving it, and after ſome time he put it down and took up the ſtrawberry, which he almoſt immediately ate. Hence it might be ſuppoſed, on the one hand, that there was an operation of reaſoning ; and, on the other, that it was ſimply a judgment, formed by compariſon of the ſenſations.

The truth appears to lie between the two ſuppoſitions. As far as we can form an idea of the operation of the infant mind, the caſe was this. There certainly was conſiderable reſemblance between the two objects, or the child (whoſe diſcriminative powers were obviouſly clear) would have at once choſen the right one ; but having taken up the daiſy, it did not, on minute obſervation, preſent thoſe appearances which excited the connected pleaſurable feelings, already aſſociated with the conception and name of the ſtrawberry, and conſequently did not excite the diſpoſition to eat it. The judgment was not a direct intentional one, and conſequently differed from thoſe which we employ by the uſe of words ; but the proceſs was the ſame with that which continually takes place in our own minds. The rejection of the daiſy was in conſequence of the perception of diverſity, or at leaſt the want of perception of complete ſimilarity between the ſenſation and the conception which had been produced by the frequent ſight of the fruit. In this inſtance we have no doubt that words were employed to ſet the compariſon in motion. Children often underſtand many words before they can at all utter articulate ſounds. The child was probably told that one was a ſtrawberry and the other a daiſy, and that he might eat the ſtrawberry.

Such compariſons ſhould often be produced, but at firſt the objects ſhould, as much as poſſible, be ſuch, that the compariſon may be ſuggeſted by the wants of the caſe ; and it ſhould, conſequently, be always employed on objects which are completely within the graſp of the mind, at leaſt in the view which we wiſh to have taken of them. It would be abſurd, for inſtance, to lead a child to compare any of the qualities of a guinea and a ſhilling, but thoſe which are obvious to the ſight or the touch. Inſtances will be continually occurring (where proper room is given for the exerciſe of the faculties), in which compariſon will take place without any effort on the part of the parent ; but it will uſually be found expedient ſometimes to bring about the employment of the judgment directly ; and provided we take care never to make it painful, by diſpleaſure at inaccuracy, or by too much ſolicitude as to the reſult, it may be done with great advantage. We never can be without objects to exerciſe compariſon, when children underſtand the meaning of common words, even if they cannot themſelves properly employ them. The ſize of things, their colour, ſhape, ſmoothneſs, weight, &c. (according to the degree in which the underſtanding is developed, and the meaning of words underſtood), furniſh conſtant means for leading to obſerve reſemblances and differences in their various combinations ; and the perception of theſe conſtitutes diſcrimination.

Theſe things would doubtleſs appear trifling to many of our readers ; but in all probability thoſe who may conſult this article will view things in a different light. Diſcrimination of judgment is a quality than which no one is more eſſential in the purſuit of truth ; the ready perception of reſemblances among diverſities, and ſtill more the quick and accurate perception of diverſity in the midſt of reſemblances, conſtitute ſome of the moſt important operations of the underſtanding. And ſuch diſcrimination will uſually be produced, where the mind is awakened by having ſufficient ſcope and exerciſe of its faculties. We may often leave it to its own ſilent progreſs ; and if we encourage accurate and attentive obſervation, and the correct uſe of words, diſcrimination will, in all probability, be found to follow as a natural conſequence. But it muſt alſo be our endeavour, to awaken and exerciſe the mind by direct attention on our part ; and provided we meaſure our efforts by the degree in which the underſtanding is developed, and do not attempt to force it, but only to guide and employ it, we may reaſonably indulge the confidence that the work of education is going on ſucceſsfully, and that we are beginning a progreſs of intellect, from which the moſt ſatisfactory reſults may be expected.

This quality of accurate diſcrimination ſhould be kept in view and exerciſed in every part of education. It is, indeed, the foundation of clear ideas; and the acquiſition of whatever can be truly called knowledge depends moſt materially on the poſſeſſion of it. It is exerciſed by various objects of inſtruction; and in fact it often is this exerciſe which gives thoſe objects their leading value. Now, if we wiſh our children to think clearly, and to reaſon accurately, the works of thought and reaſoning muſt be attended to early. Thoſe who learn to think and reaſon comparatively late in life, have difficulties to overcome which can ſcarcely be appreciated by thoſe whoſe intellectual qualities have been early cultivated. And no ſenſible parent need deſpair on this point. The object to which we would urge, is not to communicate extenſive information; that will be gained, and beneficially gained, if the deſire of knowledge have been produced, and the qualities of mind, on which the acquiſition of knowledge depends, have been properly trained; we only wiſh that on thoſe objects which properly fall within the ſphere of capacity, during the early part of childhood, the obſervation ſhould be ſo exerciſed, that the power of diſcrimination ſhould be acquired. A few ſimple play-things, which a child has the opportunity of obſerving in every ſituation, the natural objects which ſurround us, and which uſually ſtrike the attention of a child, if he be allowed to obſerve, pictures of different kinds of animals, the letters of the alphabet, the diſſected map, &c. furniſh abundant opportunities for that diſcrimination, the cultivation of which we ſtrongly recommend, as lying at the foundation of every thing which is valuable in the moſt ſerviceable exerciſes of the judgment. All that is requiſite is, that we ſhould ourſelves be capable of diſcrimination; that we watch the opportunity, when the mind is alive, to encourage the obſervation, and to produce diſtinct and accurate perceptions. Our buſineſs is not to be continually making direct efforts, as in the later period of education, but to employ thoſe occaſions which ſo often preſent themſelves to the attentive parent, to lead to the exerciſe of thoſe qualities of mind which he knows to be of high importance. It ſcarcely matters what it is on which we do thus exerciſe them; provided always that we attend to the actual ſtate of the mental progreſs; circumſtances which, to unintereſted ſpectators, appear of the ſlighteſt poſſible moment, often to the judicious parent indicate the operation of ſome uſeful quality, and enable him to diſcover, more than any ſpecific directions can do, what will enable him to promote thoſe qualities of mind which he wiſhes to ſee poſſeſſed. The grand point to be kept in view is, that we do not aim, on any occaſion, to force the faculties, but to employ them as they advance in ſtrength and accuracy ſuitably to their progreſs, and to furniſh them with appropriate objects of exerciſe: and we may feel aſſured, that ſo long as thoſe qualities are exerciſed, the buſineſs of education is going on much better than if we were endeavouring to ſtore the memory with words to which indiſtinct ideas, or no ideas at all, are attached, or even to ſtore it with facts, however in themſelves conſidered uſeful and intereſting. We ought never to think the work of education going on, unleſs the operations of the underſtanding are in ſome way or other brought into exerciſe: and when they are, we may reſt fully ſatisfied. If the developement of the intellectual faculties is properly begun, it will go on by the mere influence of external impreſſions. Our buſineſs is to regulate and employ thoſe external impreſſions, ſo that their influence may be ſuited to the ſtate of the mind, and really productive of a ſuitable exerciſe of the underſtanding.

We ſhould aim not only to produce diſcrimination, but to lead to the habit of obſerving the grounds of diſcrimination, the particular qualities or circumſtances in which objects reſemble one another, and thoſe in which they differ. This is by no means a neceſſary effect of the perception of reſemblance or difference; and it is often but partially acquired; yet it is certainly eſſential to correct reaſoning, and may be properly included under the head of diſcrimination. Children very early acquire the power of finding out the grounds of difference and agreement: and the queſtions, In what are theſe two things alike? In what are they unlike? often ſerve, at the age of three or four years, to bring into exerciſe ſome of the moſt uſeful operations of the underſtanding. Every thing, in fact, which ſets children to think upon the objects of their ſenſations, and upon their ideas, is a moſt ſerviceable employment: and the more they are early led to think correctly, the more eaſy in the later periods of education will correct thought become.

It would often ſerve as an important guide, if parents would themſelves conſider what qualities, or faculties of mind, are brought into exerciſe by the different circumſtances which occur, by their own words to their children, and the modes of expreſſion which they encourage them to uſe. We ſhould always wiſh that intellectual education ſhould be made ſubſervient to moral education; but attention to the one would in no way interfere with attention to the other. A ſound, comprehenſive, vigorous, diſcriminating judgment, is ſurely of the firſt importance, both in a moral and in an intellectual point of view. There can be no doubt that much might be done towards the acquiſition of it, if parents kept it in ſight as the chief mental object, and regulated their direct efforts, and as much as might be controlled accidental impreſſions, with a view to the cultivation of it, uſing their own good ſenſe and patient obſervation as the beſt guides to the probable effect of each upon the mind.

IX. *Reaſoning*, or the drawing of inferences, is a proceſs which may be expected to go on ſucceſsfully where the judgment has been cultivated. It begins very early; indeed the mental proceſs is often independent of words. The direct exerciſe of it does not appear to be deſirable, till the mind has acquired ſome vigour; more eſpecially till the judgment has been tolerably cultivated, and a conſiderable acquaintance with words acquired: and this is the leſs neceſſary, becauſe in every part of early education, circumſtances of conſtant occurrence will continually bring the reaſoning faculty into exerciſe, and give it a right direction, if we avail ourſelves of the opportunities which they preſent. "Scarcely a day paſſes," ſays Miſs Edgeworth, "in which children do not make ſome attempt to reaſon about the little events which intereſt them, and upon theſe occaſions a mother who joins in converſation with her children may inſtruct them in the art of reaſoning without the parade of logical diſquiſitions."

As the mind expands, the objects of the reaſoning faculty, of courſe, increaſe in number and frequency of occurrence. And the judicious parent, without making it a formidable object, may exerciſe it effectually. Two points, which are of univerſal application, ſhould, however, be always kept in view; that the premiſes ſhould be thoroughly underſtood, and this previouſly to the employment of them in the act of reaſoning; and that the aſſent of a child to the concluſion ſhould never be exacted, when there is any heſitation. It is too much to expect from a child, that the concluſion ſhould be admitted, if the underſtanding is to be exerciſed upon the premiſes alſo: and as we cannot force the reaſoning powers, and cannot compel a child to ſee the juſtneſs of our reaſonings, we ſhall either lead him to falſehood by too great eagerneſs, or to aſſent upon our authority and not upon the effect of the premiſes; or, we ſhall confuſe his underſtanding, and really prevent that effect which would otherwiſe have readily followed.

Single acts only of reaſoning ſhould be exerciſed in the early periods of education. We do not mean that one inference ſhould never be made to follow another, after the underſtanding had previouſly acquired ſome ſtrength and clearneſs: but that, if ever a train of reaſoning be employed, it ſhould, in fact, be made to conſiſt of ſingle unconnected reaſonings in the firſt place. The links ſhould be all comprehended ſeparately before they are faſtened together. When a child is ſo far advanced as to be able to purſue a train of premiſes and concluſions, there can be no loſs for ſubjects on which to exerciſe the reaſoning faculty: the fields of mathematical ſcience will by that time be opening, and they will exerciſe it, and, at the ſame time, guide it.

It appears that, in general, the true method of teaching to reaſon accurately, is to accuſtom children to accurate reaſoning. Long before they can form inferences for themſelves, they can underſtand the inferences of others; and the grand point is, that the reaſonings which we employ to them ſhall be fully intelligible and thoroughly juſt. If we are ſophiſtical with them, it is too much to expect that they will grow up in habits of clear and correct reaſoning. If we make a point of going no farther in our concluſion than our premiſes will warrant, they will gradually acquire a kind of tact, which may be conſidered as forming a part of good ſenſe, which will effectually prevent them from feeling ſatisfied with falſe reaſoning, even though they could not detect the grounds of the ſophiſtry.

Parents muſt often require the aſſent of their children on the ſcore of authority. They will naturally believe implicitly, if the truth is always ſpoken to them; and it is ſometimes impoſſible to give them any reaſon which would be intelligible and ſatisfactory to themſelves in reply to their queſtion, Why? or, Why not? We prefer that children ſhould be troubleſome ſometimes with theſe enquiries, rather than that they ſhould not themſelves be accuſtomed to think; and if a parent has, by judicious management, acquired the confidence of his children, it will generally be ſufficient for him to ſay, "It is not always neceſſary that I ſhould tell you the reaſon of what I deſire you to do; I wiſh you to do it:" and in ſome caſes, indeed, not unfrequently, it may be expedient to ſtate what is often the matter of fact, "You are not old enough to underſtand the reaſon, if I were to tell it to you: when you have more knowledge and underſtanding, I ſhall be able to tell you the reaſons of thoſe things better than I can now." But after all, if aſſent, or obedience, be required on the ground of authority and confidence, let the ground of reaſoning be kept out of view. If we once make any thing depend upon our reaſoning being underſtood, let it be kept to that point. We may often aſſent to the concluſion as an inſulated truth; but we never can aſſent to it as an inference, unleſs the reaſoning is properly underſtood.

It may be doubted whether it is deſirable to give ſpecimens of ſophiſtry to children, before they are really capable of entering into the ground of the ſophiſtry. But if ever we find them drawing falſe concluſions, then is the time to ſhew them, if poſſible, how and why they are falſe. And it is highly deſirable that we ſhould accuſtom them to caution in their inferences. It is better that they ſhould ſometimes reaſon very erroneouſly, and draw very erroneous concluſions, than that they ſhould never reaſon at all; and it is by no means to be expected, or even wiſhed, that their inferences ſhould be always accurate: it is not to be wiſhed, becauſe we ſhould then have reaſon to apprehend, that the inference was an act of memory rather than of the underſtanding; and it cannot reaſonably be expected, becauſe the power of reaſoning juſtly depends upon the degree in which the terms of the premiſes are clearly and fully underſtood, and alſo requires, for the acquiſition of it, a long courſe of exerciſe. Nevertheleſs, the habit ſhould be early produced of caution in receiving or in drawing inferences. We would never have children ſuſpect the accuracy of their parents; but we ſhould ſhew them in what they hear (if it can be done with prudence), and ſtill more in their own little reaſonings, thoſe defects which their minds are ſufficiently cultivated to perceive. And without giving riſe to a habit of indeciſion, (which ſometimes is as injurious as a habit of preſumption,) we ſhould aim to lead them to take as many circumſtances as poſſible into account, and not to be too decided with reſpect to inferences which may be drawn from them. If a child once ſees that he has inferred too much, it will effectually keep him, for a time at leaſt, from preſumption, eſpecially in oppoſition to the inferences of others.

In order to acquire that freedom from the influence of authority which is often neceſſary to ſucceſs in the purſuit after truth, it is requiſite that children be accuſtomed, and encouraged, to ſtate their difficulties and objections againſt any reaſoning or aſſertion which they hear or meet with in books. We have no wiſh to ſee the habit of objecting for the ſake of objecting: but thoſe are the moſt likely to acquire it, who have been accuſtomed to think but little when young, and to take every thing upon truſt. Having believed every thing upon authority, when their minds acquire ſome degree of independence and activity, they uſually find, or think they find, that many of thoſe things which they have believed are inconſiſtent with truth, and they feel a kind of general ſuſpicion, with reſpect to all which they have been aocuſtomed to believe; and the conſequences often are highly injurious both with reſpect to the underſtanding and the conduct. Though we wiſh to ſee an unbounded confidence in parental declarations, and unlimited ſubmiſſion to parental authority, yet a parent ſhould employ each only for the good of his children. It will not excite ſuſpicion, if he ſometimes lead them to perceive, that he is not equally ſure of every thing that he tells them; that when they grow older they will perhaps underſtand ſome things better even than himſelf; and that at any rate they muſt learn to think for themſelves, ſince he ſhall not always be at hand to inſtruct and guide them. He will always point out, or, what is better, lead them to find out, errors in reaſoning, &c. in the books which they read, eſpecially though the writers were men of great eminence. He will accuſtom them to think for themſelves; but at the ſame time he will make them underſtand that they are not to reject every thing becauſe they ſee that ſome things are erroneous. If the mind have been rightly trained, while its education is principally conducted by others, things will go on well when the individual has, as it were, to educate himſelf. If by early diſcipline, followed up by the well regulated purſuit of uſeful knowledge, he have been brought into that invaluable ſtate of mind, in which freedom of thought is united with caution, and a tendency to ſuſpect one's own concluſions, at leaſt as much as thoſe of others, it may reaſonably be expected that the acquiſition of truth will be an eaſy taſk, and that the judgment will have that clearneſs, activity, and correctneſs, which will enable the poſſeſſor to chooſe important objects, and to purſue them by ſuitable and judicious means.

X. After all, perhaps, the moſt important object in early intellectual education, next to the cultivation of the perception, is that which reſpects *Words:* at leaſt, this is of eſſential importance. A clear and correct underſtanding of the force of words, is of the utmoſt conſeqcence in every period of the intellectual progreſs. On the care which is early taken in furthering this object, depend, in a great meaſure, the future developement of the underſtanding and the acquiſition of knowledge. A well-educated child will always heſitate to uſe words which he does not ſo far underſtand as to be able to feel their force in the particular connection: and in many inſtances this is all which can be underſtood by a child. The names of external objects, are, of courſe, the firſt words which are acquired and underſtood: and here all is plain. Either the things themſelves can be ſhewn, and the words connected with them; or pictures can be employed to repreſent to the mind what cannot be directly made the ſubject of perception. In like manner, names denoting the actions of animated objects, and the changes which take place among inanimate objects, the ſenſible qualities of the different ſubſtances around, and, in ſhort, any thing which can be made the ſubject of direct ſenſation, or can be repreſented to the ſight, are calculated for the early exerciſe of the aſſociative power. And it is in the application of theſe, that the earlieſt efforts of claſſification are employed. The ſame name is unavoidably given to a variety of things or animals agreeing in ſome particulars; and indeed this circumſtance is of the utmoſt conſequence to the progreſs of intellect. It may be truly ſaid, that without general terms little knowledge could be acquired, that there would be almoſt a total ſtop to every proceſs of mind not immediately depending upon ſenſation. In the firſt periods of language the buſineſs of claſſification, and the application of general terms, went on together; the proceſſes of claſſification are now, however, in innumerable inſtances, directed by the cuſtomary mode of applying the terms. Still the application of them is accompanied with claſſification; and when the mind is, in ſome inſtances, a little familiarized with the operation, it acquires, with great eaſe, the mode of applying general terms in others. This is an excellent and important exerciſe of the judgment; and it leads to notice circumſtances of agreement and circumſtances of difference, which is in itſelf a highly uſeful employment of the underſtanding. In ſome inſtances children cannot but be puzzled, either by the unavoidable irregularities of language, or by the application of terms depending upon little niceties which cannot be expected to lie within the ſphere of their obſervation; but wherever the grounds of the application can be ſhewn, it will always furniſh a uſeful exerciſe of the mind to be led to obſerve them as ſuch.

We have already referred to the great importance of the mathematical ſciences in training the mind to habits of correct reaſoning; indeed it is by the various acquiſitions of knowledge, that the different mental faculties are developed and cultivated; and we fully expect the concurrence of our readers when we ſay, that an early and accurate acquaintance with our arithmetical notation and numeration, is peculiarly calculated to lay the foundation of habits of preciſion, of arrangement and claſſification. Our notation took its riſe in the neceſſities of circumſtances, operating upon thoſe powers and qualities of mind which are poſſeſſed by every human being; but it is an object worthy of the attentive examination of the philoſopher, while, at the ſame time, from its diſtinctneſs and ſimplicity, it ſerves as a moſt important exerciſe to the juvenile underſtanding. A child, early made familiar with the ſimple operations of arithmetic, (taught, not technically, but by a conſtant reference to the principles on which they are founded, and particularly to thoſe of the notation, on which in ſhort the whole depends,) can ſcarcely fail to form ſome preciſe ideas, and to acquire a tendency to arrangement and method, which will almoſt inevitably lead on to a ſimilar employment of the underſtanding in other circumſtances. It may not perhaps be known to all our readers, that there is an excellent poſthumous work of Condorcet, which will furniſh ſome highly valuable information to the intelligent parent, on the beſt means of communicating an acquaintance with the firſt principles of arithmetic. It is entitled, "Moyens d'apprendre à compter ſurement et avec facilité." If it were more the object of early education to cultivate the faculties of the mind, rather than to ſtore the memory with words, or with ideas, which are of little importance except ſo far as they are made an exerciſe of the underſtanding, this little tract would not have been ſo long left inacceſſible to the mere Engliſh reader. The French editor juſtly remarks, that the firſt thing which diſtinguiſhes theſe elements of arithmetic, is, that they are at the ſame time the elements of the art of reaſoning. The uſual formulæ of arithmetic are founded upon principles and proceſſes which can generally be made intelligible to thoſe who are capable of employing them; but the formulæ do not of themſelves ſufficiently exerciſe the underſtanding: they are a ſpecies of machinery with which we operate almoſt mechanically. But in ſo far as thoſe principles and proceſſes are made intelligible and familiar, the judgment is cultivated, the reaſoning powers are exerciſed, diſtinct ideas are gained, and the commencement made of thoſe intellectual operations and habits, which are ſubſervient to the higheſt purſuits of knowledge, and to the beſt conduct of life.

While we thus recommend the early employment of the underſtanding upon numbers, we ought not in juſtice to ourſelves to omit mentioning, that natural hiſtory furniſhes ample ſcope for the exerciſe of the intellect on things, on words, and in claſſification; and in ſome reſpects it is a more uſeful object of early mental culture; it brings into exerciſe the habit of obſervation, while it equally requires and more rewards the attention; it gives more room for the exerciſe of the memory, and is more calculated to ſet the mind at work, and ſupplies more numerous and intereſting ſubjects for its operations. "The art of forming a ſound and active underſtanding," ſays Miſs Edgeworth, "conſiſts in a due mixture of facts and reflection. Dr. Reid has, in his Eſſay on the Intellectual Powers of Man, p. 297, pointed out, with great ingenuity, the admirable economy of nature in limiting the powers of reaſoning during the firſt years of infancy. This is the ſeaſon for cultivating the ſenſes, and whoever, at this early age, endeavours to force the tender ſhoots of reaſon, will repent of his raſhneſs." We have not yet been able to meet with the paſſage to which Miſs Edgeworth refers in our 8vo. edition of Reid; but we are fully convinced that ſhe cannot go the whole lengths of that philoſopher, reſpecting the degree in which the reaſoning faculty is naturally developed, or rather lies undeveloped, during *childhood:* as we have already remarked, children reaſon much more than is uſually ſuppoſed: and provided we are cautious in giving due vigour to the obſervation and judgment, we may ſometimes directly employ the reaſoning faculty, under the reſtrictions which we have already pointed out. Perhaps, however, it is better to be ſatisfied with thoſe proceſſes of reaſoning, which, where the mind is healthy, will almoſt inevitably follow the exerciſes of the obſervation and recollection, and make no direct effort to cultivate the reaſoning faculty, than to aim to bring it forwards prematurely; and it was with a view to this principle, that we have thought it deſirable to ſubjoin the foregoing remarks to what we have ſaid on attention to numbers.

In many caſes the force of words can only be learnt gradually, by their uſe in various connections: to attempt to explain connectives, for inſtance, by aſſigning their abſtract force, would be utterly uſeleſs to a child; the force of them muſt be ſhewn in particular caſes, and from theſe the mode of applying them, and the force of them will be learnt in others. Similar remarks may be made with reſpect to all abſtract terms: and provided we are careful ourſelves to employ them properly, and to take every opportunity of ſhewing the force of them when level to the capacity or progreſs of the individual, we do all which is neceſſary, and probably do better than by attempting to do more.

Though we fully calculate on our readers going along with us, reſpecting the abſolute neceſſity of early accuſtoming the mind to ſeek for, and to acquire, clear ideas in connection with the ſigns of ideas, the following remarks of Mr. Locke may ſerve to corroborate their opinions; and, together with what we ſhall alſo quote from Miſs More, may lead them to make it an object of daily, indeed conſtant, aim in the buſineſs of education, not merely as of great moment in intellectual cultures, and to ſmooth the way for intellectual acquiſitions, but as incumbent on every one who has in view the moral welfare of his child. "Perſons having been accuſtomed from their cradles," ſays our great philoſopher, "to learn words before they knew the ideas for which they ſtand, uſually continue to do ſo all their lives, never taking the pains to ſettle in their minds the determined ideas which belong to them. This want of a preciſe ſignification in their words, when they come to reaſon, eſpecially in moral matters, is the cauſe of very obſcure and uncertain notions. They uſe theſe undetermined words confidently, without much troubling their heads about a certain fixed meaning, whereby, beſides the eaſe of it, they obtain this advantage, that as in ſuch diſcourſe they are ſeldom in the right, ſo they are as ſeldom to be convinced that they are in the wrong, it being juſt the ſame to go about to draw thoſe perſons out of their miſtakes, who have no ſettled notions, as to diſpoſſeſs a vagrant of his habitation who has no ſettled abode. The chief end of language being to be underſtood, words ſerve not for that end when they do not excite in the hearer the ſame idea which they ſtand for in the mind of the ſpeaker."

"I have choſen," adds Miſs More, after making the foregoing extract, "to ſhelter myſelf under the broad ſanction of the great author here quoted, with a view to apply this rule in philology to a moral purpoſe; for it applies to the veracity of converſation as much as to its correctneſs; and as ſtrongly recommends unequivocal and ſimple truth, as accurate and juſt expreſſion. Scarcely any one perhaps has an adequate conception, how much clear and correct expreſſion favours the elucidation of truth; and the ſide of truth is obviouſly the ſide of morals; it is in fact one and the ſame cauſe; and it is of courſe the ſame cauſe with that of true religion alſo.

"It is therefore no worthleſs part of education, even in a religious view, to ſtudy the preciſe meaning of words, and the appropriate ſignification of language. To this end, I know no better method, than to accuſtom young perſons very early to a habit of defining common words and things; for, as definition ſeems to lie at the root of correctneſs, to be accuſtomed to define Engliſh words in Engliſh, would improve the underſtanding more than barely to know what thoſe words are called in French, Italian, or Latin. Or rather, one uſe of learning other languages is, becauſe definition is often involved in etymology, that is, ſince many Engliſh words take their derivation from foreign or ancient languages, they cannot be ſo accurately underſtood without ſome knowledge of thoſe languages; but preciſion of any kind, either moral or philological, too ſeldom finds its way into the education of women."

If any of our readers wiſh for an exemplification of the method of teaching to define, we refer them, with complete ſatisfaction, to the excellent little work called "Evenings at Home;" the attentive peruſal of which muſt furniſh to the judicious parent, many uſeful reflections and hints calculated to facilitate his views in intellectual education. We may mention in paſſing, that we cannot but conſider it as a duty which the reſpectable author owes to the public, to make thoſe alterations in the chemical articles which may adapt it more to the preſent ſtate of the ſcience; and we are perſuaded that he could not render a more uſeful ſervice to the riſing generation, than by ſome ſupplementary volumes on other points of natural hiſtory and phyſiology, and natural philoſophy, calculated, as thoſe preceding eminently are, to convey clear ideas, and to exerciſe the underſtanding. We need ſcarcely add, that the mathematical ſciences furniſh moſt important leſſons in the art of defining, and ſome of the fineſt and moſt uſeful ſpecimens of it.

With reſpect, however, to the plan of definitions, we muſt again obſerve, that in a great variety of inſtances we muſt reſt ſatisfied with perceiving that the force of a word is clearly underſtood in the particular caſe; and we muſt ſometimes require even leſs than this. Words which are the moſt forcible to our minds, in conſequence of numerous aſſociated thoughts and feelings, often can ſcarcely affect the mind of a child. The force of thoſe which repreſent very complex ideas (as moſt general terms do), muſt generally be acquired ſlowly, by the impreſſions derived from the manner of their employment, and the inſtances of their application. But wherever the force of a word can be explained, ſo as to be made intelligible, this ſhould be done; and there can be no doubt that the habit ſhould be formed as early as poſſible, of never reſting ſatisfied without ſome ideas connected with the words which occur in books on converſation. We have ourſelves had an opportunity of obſerving the great value and force of this habit. A young perſon, who, in the courſe of his reading aloud with his early inſtructor, had uniformly been called upon to try to explain the meanings of words, and in caſe of failure had as uniformly been ſent to ſearch for a ſuitable explanation in a good dictionary which was always at hand, by degrees became ſo much accuſtomed to this exerciſe of the underſtanding, that, when arrived at years of maturity, he felt a kind of internal compulſion to reſort to the ſame means of information, when he could not otherwiſe aſcertain to his ſatisfaction the force of a word in a given ſituation, which feeling generally overcame the reluctance of indolence, and even the eagerneſs which ſo often urges on the ardent mind towards that which is yet unexplored. The effect of ſuch diſcipline upon the habit of diſcrimination and clearneſs of intellect need not be pointed out. It can ſcarcely fail to bring the mind into the right ſtate for the ſearch after truth; and even if only defective ideas are thus acquired, yet if correct as far they go, the grand point is gained. After ſuch habitual culture of the mind, the want of ſomething upon which the underſtanding may reſt with ſatisfaction is conſtantly felt; and if the whole truth is not graſped, the acquiſitions actually made will uſually be on the ſide of truth.

It appears highly inexpedient to attempt, in the early periods of the mental progreſs, to give the moſt comprehenſive meanings of words. The firſt buſineſs in the early acquiſition of knowledge, is to begin with individuals, and after a ſuitable acquaintance has been gained with them, to go on to general facts and ſtatements. In like manner with reſpect to words, it is ſufficient if we can give a clear idea of the ſignification of a word as it occurs: it will afterwards be an excellent employment of the underſtanding to combine theſe meanings together, ſo as to generalize the term; and where the mind has been well cultivated, this will be done almoſt without our direct efforts. But it ſhould not unfrequently conſtitute a direct exerciſe in the more advanced periods of education, to trace out that common ſignification which a word has throughout all its varieties of ſignification; and previouſly to this, it is deſirable to accuſtom the young to expect that the particular force of a word which they have acquired is by no means the only one, and to be ready to receive the change of meaning which the circumſtances of the connection may require, or which the writer may, by his definitions, endeavour to communicate to his readers.

The wrong application of words is one of the chief obſtacles in the acquiſition of knowledge, and conſtitutes the cauſe of ſome of our earlieſt and ſtrongeſt prejudices. By the magic power of aſſociation, not only do the connections of ideas ſuggeſt combinations of words, but combinations of words, in innumerable inſtances, produce connections of ideas. And this ought to furniſh to the early inſtructor, a powerful motive to caution in the employment of words; ſo that, in his communications with his pupils, he may avoid, not only thoſe modes of expreſſion which are in themſelves calculated to convey wrong ideas, but thoſe alſo which muſt convey wrong ideas in conſequence of the partial knowledge poſſeſſed by thoſe who hear them. It ſhould be a leading object, in every department of education, ſince it is totally impoſſible to give full and complete ideas, to render thoſe which we can communicate clear and correct. Where this object is ſteadily purſued, the underſtanding may be expected for itſelf to ſeek, and will, in all probability, acquire all which is neceſſary beyond.

But notwithſtanding all the care and ſelf-culture of parents and inſtructors, numerous erroneous aſſociations will be formed or imbibed, which will warp the judgment from the perception of truth, and ſometimes obſcure it. A large proportion of them operate through the medium of the affections; and ſome attention will be paid to theſe under the head of MORAL *Education*; but ſtill many remain which ariſe from the ambiguities of language, from partial obſervation, from accidental combinations of external objects, &c. Theſe will often give way to the gradual developement of the mental faculties, and the acquiſition of knowledge; but ſometimes theſe irregular aſſociations will continue for a long period to perplex and miſlead the underſtanding. It is highly deſirable, therefore, to watch for them, and, where they are diſcovered, to take ſuitable means for deſtroying them. When we perceive a want of readineſs to admit obvious truths which are level to the progreſs of the intellect, we may uſually conclude that ſome incorrect idea has been connected with the words employed. Sometimes the immediate end may be gained by a change of words; but it is, perhaps, generally preferable to endeavour to enter into the little mind and trace its errors and their ſources. We remember once diſcovering that a child had formed the prepoſterous idea, that the duſt which flies about in the road is in part compoſed of the particles of the human body; an idea derived (by ſome proceſs of reaſoning, which we do not now recollect, aided no doubt by an effort of the imagination,) from impreſſions received from the words in the burial ſervice, "duſt to duſt." Here, and in ſimilar caſes, to diſcover the link and to ſeparate it, are almoſt the ſame thing. It is one great advantage of domeſtic education, that it enables the parent or inſtructor to watch over the early aſſociations, and to prevent the formation, or effect the diſunion, of many which are injurious to the acquiſition of knowledge, and what is ſtill more important, unfriendly to the moral judgment, and to the happineſs of the individual. To have the power of availing themſelves of this advantage, however, parents muſt accuſtom their children to view them as friends, to open their little minds to them with the utmoſt confidence; they muſt treat their erroneous judgments with mildneſs, and be habitually careful in their own modes of expreſſion in their preſence, and eſpecially in their direct communications with them.

Before quitting the ſubject of words we would add, that it is very deſirable to accuſtom children to the peculiar terms of ſcience and art, as ſoon as they can underſtand their meaning. In very many inſtances this can be done with eaſe, not as a formal object, but in the courſe of converſation, or while explaining what is met with in books. When the terms are become familiar, and are pretty well underſtood, the difficulties attending the acquiſition of any ſcience are greatly leſſened. Even familiarity with the mere words employed, is of ſome ſervice when we begin a new branch of knowledge; but in many caſes even clear ideas may be early obtained in connection with ſcientific language, which will effectually prepare the way for future progreſs. Suppoſe, for inſtance, the leading terms of geometry are early explained, by means of figures or models, not only will the underſtanding receive ſome exerciſe by the acquiſition of diſtinct ideas in connection with words, but it will be ready whenever the reaſoning powers are ſufficiently matured to be directed to geometry, to enter upon the field without that perplexity which is ſo often produced by the multitude of new words as well of new ideas. The utmoſt care ſhould, however, be taken to make our explanations correct as far they go. If poſſible, children ſhould have nothing to unlearn; and though we cannot effect this completely, yet more depends than is uſually ſuppoſed upon thoſe who have to guide the early aſſociations and mould the habit; and the leſs error enters the mind, the more readily will truth find admittance.

XI. "It is more likely," ſays Miſs Edgeworth, "that *wit* ſhould be engrafted upon judgment, than that judgment ſhould be engrafted upon wit." Numerous excellent obſervations may be found in her Practical Education reſpecting the cultivation of the underſtanding; we ſhall conclude what we have advanced on the ſubject, by quoting her very judicious remarks on the ſubject of the early cultivation of wit.

"We have adviſed, that the judgment of children ſhould be exerciſed upon the objects of their ſenſes. It is ſcarcely poſſible that they ſhould reaſon upon the ſubjects which are ſometimes propoſed to them: with reſpect to manners and ſociety, thay have had no experience, conſequently they *can* form no judgment. By imprudently endeavouring to turn the attention of children to converſation that is unſuited to them, people may give the *appearance* of early intelligence, and a certain readineſs of repartee and fluency of expreſſion; but theſe are tranſient advantages. Smart, witty children amuſe the circle for a few hours, and are forgotten; and we may obſerve, that almoſt all children who are praiſed and admired for ſprightlineſs and wit, reaſon abſurdly, and continue ignorant. Wit and judgment depend upon different and oppoſite habits of mind. Wit ſearches for remote reſemblances between objects or thoughts apparently diſſimilar. Judgment compares the objects placed before it, in order to find out their differences rather than their reſemblances,

blances. The compariſons of judgment may be ſlow; thoſe of wit muſt be rapid. The ſame power of attention in children may produce either wit or judgment. Parents muſt decide in which faculty, or rather, in which of theſe habits of the mind, they wiſh their pupils to excel; and they muſt conduct their education accordingly. Thoſe who are deſirous to make their pupils witty, muſt ſacrifice ſome portion of their judgment to the acquiſition of the talent for wit; they muſt allow their children to talk frequently at random. Amongſt a multitude of hazarded obſervations, a happy hit is now and then made: for theſe happy hits children who are to be made wits ſhould be praiſed; and they muſt acquire ſufficient courage to ſpeak from a curſory view of things; therefore the miſtakes they make from ſuperficial examination muſt not be pointed out to them; their attention muſt be turned to the comic rather than to the ſerious ſide of objects; they muſt ſtudy the different meanings and powers of words; they ſhould hear witty converſation, read epigrams and comedies: and in all company they ſhould be exerciſed before numbers in ſmart dialogue and repartee.

"When we mention the methods of educating a child to be witty, we at the ſame time point out the dangers of this education: and it is but juſt to warn parents againſt expecting inconſiſtent qualities from their pupils. Thoſe who ſteadily prefer the ſolid advantages of judgment to the tranſient brilliancy of wit, ſhould not be mortified when they ſee their children, perhaps, deficient at nine or ten years old in the ſhowy talents for general converſation; they muſt bear to ſee their pupils appear ſlow; they muſt bear the contraſt of flippant gaiety and ſober ſimplicity; they muſt purſue exactly an oppoſite courſe to that which has been recommended for the education of wits; they muſt never praiſe their pupils for hazarding obſervations; they muſt cautiouſly point out any miſtakes that are made from a precipitate ſurvey of objects; they ſhould not harden their pupils againſt that feeling of ſhame which ariſes in the mind from the perception of having uttered an abſurdity; they ſhould never encourage their pupils to play upon words; and their admiration of wit ſhould never be vehemently or enthuſiaſtically expreſſed."

XII. *Imagination* reſpects the thoughts and the feelings. Conſidered in reference to the conceptions and trains of thought, it properly falls under the head of Intellectual Education: conſidered in reference to pleaſure and pain, it comes under the head of Moral Education. How the imagination affects the moral judgments, and what influence its pleaſures and pains have upon the happineſs of life, how they are to be cultivated, and how regulated, will probably be the ſubject of ſome remarks in a ſubſequent article: our buſineſs in this will be very brief.

Conſidered as an intellectual faculty, as aſſiſting to raiſe the mind above mere ſenſation, as preſenting to the mind conceptions, or trains of conceptions, which are not immediately derived from ſenſation, (though of courſe compoſed of the elements which ſenſation furniſhes,) as forming new combinations of ideas, or as ſuggeſting the grounds of reaſoning, the operations of the imagination are very important, and indeed not only powerfully aid the exerciſe of the judgment, and the purſuits of philoſophy, but are even eminently ſubſervient to the cauſe of morality. Mr. Stewart furniſhes us with many admirable obſervations, which will aſſiſt in ſhowing the point to which we ſhould endeavour to raiſe the imagination, as well as the limits which we ſhould aim to preſcribe to it; and from theſe we ſhall ſelect the following, as immediately bearing upon our object:

"Point out to two men," ſays this elegant and intereſting writer, "any object of compaſſion;—a man, for example, reduced by misfortune from eaſy circumſtances to indigence. The one feels merely in proportion to what he perceives by his ſenſes. The other follows, in imagination, the unfortunate man to his dwelling, and partakes with him and his family in their domeſtic diſtreſſes. He liſtens to their converſation while they recal to remembrance the flattering proſpects they once indulged; the circle of friends they had been forced to leave; the liberal plans of education which were begun and interrupted; and pictures out to himſelf all the various reſources which delicacy and pride ſuggeſt, to conceal poverty from the world. As he proceeds in the painting, his ſenſibility increaſes, and he weeps, not for what he ſees, but for what he imagines. It will be ſaid, that it was his ſenſibility which originally rouſed his imagination; and the obſervation is undoubtedly true; but it is equally evident, on the other hand, that the warmth of his imagination increaſes and prolongs his ſenſibility.

"The foregoing obſervations may account, in part, for the effect which exhibitions of fictitious diſtreſs produce on ſome perſons who do not diſcover much ſenſibility to the diſtreſſes of real life. In a novel or a tragedy, the picture is completely finiſhed in all its parts; and we are made acquainted, not only with every circumſtance on which the diſtreſs turns, but with the ſentiments and feelings of every character with reſpect to his ſituation. In real life we ſee, in general, only detached ſcenes of the tragedy; and the impreſſion is ſlight, unleſs imagination finiſhes the characters, and ſupplies the incidents that are wanting.

"It is not only to ſcenes of diſtreſs that imagination increaſes our ſenſibility. It gives a double ſhare in the proſperity of others, and enables us to partake, with a more lively intereſt, in every fortunate incident that occurs either to individuals or to communities. Even from the productions of the earth, and the viciſſitudes of the year, it carries forward our thoughts to the enjoyments they bring to the ſenſitive creation, and by intereſting our benevolent affections in the ſcenes we behold, lends a new charm to the beauties of nature.

"I have often been inclined to think, that the apparent coldneſs and ſelfiſhneſs of mankind may be traced, in a great meaſure, to a want of attention and a want of imagination. In the caſe of misfortunes which happen to ourſelves, or to our near connexions, neither of theſe powers is neceſſary to make us acquainted with our ſituation; ſo that we feel, of neceſſity, the correſpondent emotions. But without an uncommon degree of both it is impoſſible for any man to comprehend completely the ſituation of his neighbour, or to have an idea of a great part of the diſtreſs which exiſts in the world. If we feel therefore more for ourſelves than for others, the difference is to be aſcribed, at leaſt partly, to this, that, in the former caſe, the facts, which are the foundation of our feelings, are more fully before us than they poſſibly can be in the latter."

The power of forming vivid and accurate conceptions is an important acquiſition; but the true foundation of it is only to be laid in clear diſtinct perceptions; and if the imagination early gain ſuch influence as to call off the mind from obſervation, the moſt injurious effects may be expected to follow. The exerciſe of the imagination, (including, as is generally done, what Mr. Stewart denominates the conception,) is neceſſary to enable us to enter into the reaſonings of the philoſopher, where theſe reſpect individuals, as well as into the pictures of the poet, and the details of hiſtory. In reference to this laſt head, we may be allowed here to mention, that the conception aids the cauſe even of religious truth: for he who is not able, or who does not take the trouble, to picture to the mind's eye the ſtatements of the goſpel hiſtorians, will not have his judgment ſuitably affected with the reality of the facts which they record, nor will his affections be warmed as they ought to be by the contemplation of the character which, with the moſt artleſs ſimplicity, they pourtray.

Like the memory, though in a different way, the imagination ſhould be made a ſubſervient faculty; and the early cultivation of it muſt depend upon the tendency which we perceive to the exerciſe of it, and the degree in which it is likely to gain ground among the intellectual faculties. If the conceptions are very lively, and we perceive a tendency to dwell upon them inſtead of the objects of perception, our aim muſt be to invigorate the obſervation, to cultivate the judgment, and, as much as poſſible, to turn the efforts of the imagination into the channel of philoſophical invention. If, on the other hand, as is ſometimes the caſe, either from early neglect of the obſervation, or a want of what may perhaps be properly called phyſical ſenſibility, the conceptions are very dull, and the mind ſeems unable to enter into any thing which cannot be made the object of perception or abſtract reaſoning, it is perhaps deſirable, with caution, to ſtimulate the imagination: and in this view the following remarks of Miſs More appear to us to deſerve the attention of all who are concerned in education.

" I would not however prohibit ſuch works of imagination as ſuit this early period. When moderately uſed, they ſerve to ſtretch the faculties and expand the mind; but I ſhould prefer works of vigorous genius, and pure, unmixed fable, to many of thoſe tame and more affected moral ſtories which are not founded upon Chriſtian principle. I ſhould ſuggeſt the uſe on the one hand of original and acknowledged fictions; and on the other, of accurate and ſimple facts; ſo that truth and fable may ever be kept ſeparate and diſtinct in the mind. There is ſomething that kindles fancy, awakens genius, and excites new ideas in many of the bold fictions of the Eaſt. And there is one peculiar merit in the Arabian and ſome other oriental tales, which is that they exhibit ſtriking, and, in many reſpects, faithful views, of the manners, habits, cuſtoms, and religion of their reſpective countries; ſo that ſome tincture of real local information is acquired by the peruſal of the wildeſt fable, which will not be without its uſes in aiding the future aſſociations of the mind in all that relates to Eaſtern hiſtory and literature."

The imagination ſhould early be employed in what is its peculiar field, invention. We do not of courſe mean, that which has for its object to form combinations with the ſole view of pleaſing the fancy or gratifying the taſte; but that which has in view contrivances to facilitate the purpoſes of life, and the acquiſition of ſcience. We by no means wiſh to be underſtood, that in the early part of education, (and ſtill leſs in the later,) the imagination ſhould never be actively employed on works of fancy and taſte; but in a general way it ſhould be laid down as a principle, that the ſolid and uſeful qualities of the mind ſhould be cultivated firſt, the ornamental as a ſecondary object. The ingenuity and little inventions of children ſhould be encouraged; and where ſufficient ſcope is given for the play of the faculties, and there is no phyſical cauſe to prevent activity of mind, not a day will paſs, even at a very early age, without ſome employment in which the inventive power of the imagination is concerned. The inventions of children generally ariſe, in the firſt inſtance, from neceſſity; but, in their little diverſions, they often diſplay, (of courſe, in a low degree,) the exerciſe of thoſe qualities by which the moſt important combinations and inventions have been effected. As they advance in mental culture, this exerciſe of the imagination ſhould be more and more ſubmitted to the guidance of the judgment. Many of the literary and ſcientific purſuits to which the young are directed, have a tendency to cultivate a philoſophical imagination; and they furniſh numerous opportunities, which a judicious inſtructor will carefully employ, of calling forth and exerciſing its moſt important operations.

Some young perſons, we muſt be contented to allow to paſs through life, ſatisfied if we can make them comprehend the combinations and inventions of others; but it is very ſeldom, where the mind is active and unſhackled, and has been properly ſtimulated and employed by the uſual objects of mental purſuit, that it will reſt here. Either in the manner in which it attains to its concluſions, or in which it tries and applies them, or in the concluſions themſelves, it will leave the track which may have been beaten by others, and ſhew the exerciſe of invention. Novelty ought never to be our object, but truth; but it is pleaſant to ſee any indication of ingenuity; and it ſhould be remembered, that combinations and inventions which are not abſolutely new, may be ſo to the individual.

We ſhall now finiſh this head with a few more remarks from Mr. Stewart, which may ſerve as a reſtraining check upon the irregular or exceſſive exerciſe of the imagination; and may lead the judicious parent to the concluſion with which Miſs Edgeworth ends her chapter on the imagination, that it is a good ſervant but a bad maſter.

" It was undoubtedly the intention of nature, that the objects of perception ſhould produce much ſtronger impreſſions on the mind than its own operations. And, accordingly, they always do ſo, when proper care has been taken in early life, to exerciſe the different principles of our conſtitution. But it is poſſible, by long habits of ſolitary reflection, to reverſe this order of things, and to weaken the attention to ſenſible objects to ſo great a degree, as to leave the conduct almoſt wholly under the influence of imagination. Removed to a diſtance from ſociety, and from the purſuits of life, when we have been long accuſtomed to converſe with our own thoughts, and have found our activity gratified by intellectual exertions, which afford ſcope to all our powers and affections, without expoſing us to the inconveniences reſulting from the buſtle of the world, we are apt to contract an unnatural predilection for meditation, and to loſe all intereſt in external occurrences. In ſuch a ſituation too, the mind gradually loſes that command which education, when properly conducted, gives it over the train of its ideas; till at length the moſt extravagant dreams of imagination acquire as powerful an influence in exciting all its paſſions, as if they were realities.

" When ſuch diſorders of the imagination have been long confirmed by habit, the evil may perhaps be beyond a remedy; but in their inferior degrees, much may be expected from our own efforts; in particular, from mingling gradually in the buſineſs and amuſements of the world; or, if we have ſufficient force of mind for the exertion, from reſolutely plunging into thoſe active and intereſting and hazardous ſcenes, which, by compelling us to attend to external circumſtances, may weaken the impreſſions of imagination and ſtrengthen thoſe produced by realities.

" When a man, under the habitual influence of a warm imagination, is obliged to mingle occaſionally in the ſcenes of real buſineſs, he is perpetually in danger of being miſled by his own enthuſiaſm. What we call good ſenſe in the conduct of life, conſiſts chiefly in that temper of mind which enables its poſſeſſor to view at all times, with perfect coolneſs and accuracy, all the various circumſtances of his ſituation; ſo that each of them may produce its due impreſſion on him, without any exaggeration ariſing from his own peculiar habits. But to a man of an ill-regulated imagination, external circumſtances only ſerve as hints to excite his own thoughts, and the conduct he purſues has, in general, far leſs reference to his real ſituation, than to ſome imaginary one, in which he conceives himſelf to be placed; in conſequence of which, while he appears to himſelf to be acting with the moſt perfect wiſdom and conſiſtency, he may frequently exhibit to others all the appearances of folly."

XIII. In every branch of inſtruction, and in the mode of conveying it, our firſt conſideration ſhould be, its effect upon the underſtanding. The mental habits formed, rather than the number of ideas acquired, ſhould be conſidered as the leading object of attention. We have already intimated, that in a ſubſequent article we ſhall have an opportunity of ſuggeſting ſome obſervations relative to the manner of communicating knowledge, particularly of the ſcientific claſs; and we ſhall conclude our preſent article with ſome remarks which may aſſiſt in the appreciation of the value of the common objects of inſtruction in farthering the cultivation of the intellect, ſuppoſing that the beſt modes of conveying them to the mind have been ſucceſsfully aſcertained. We ſhall not attempt to follow the natural order of them; but ſhall be guided by that which appears moſt ſuitable to our object.

The acquiſition of the *dead languages* forms a leading employment in education; and we truſt it will be long before it ceaſes to be ſo, though we cannot but regret that it ſhould ever be made an excluſive object. Thoſe who know the intimate connection which ſubſiſts between the real command of words, and the nobleſt exerciſes of the underſtanding, will readily allow that the ſtudy of language forms a moſt important auxiliary in intellectual culture. We ſhall have occaſion to ſpecify hereafter to what plans of education the ſtudy of the claſſics ſhould be limited; and this will lead us to enter more at large into the importance of the object. We ſhall content ourſelves therefore, in this place, with ſtating, that the general advantages of this branch of inſtruction are, the cultivation of the habits of patience, of attention, of inveſtigation, of accuracy, of diſcrimination, and of ingenuity; the poſſeſſion of a key to the ideas contained in thoſe languages; greater power in the uſe of our own; and the acquiſition of numerous data for that branch of mental philoſophy which reſpects language.

Geography exerciſes the memory, and were it only for its ſubſerviency to hiſtory, would be highly valuable; but it has other advantages. It may be made the vehicle for various topics of information, and from theſe adjuncts, it acquires a rank in the ſcale of utility, to which, ſeparately conſidered, it would not be entitled. Independently of this, the habit of aſſociating names with things, and of arrangement, which ſeems likely to be formed by learning geography, entitle it to a place in the early part of education.

We uſe the word in its exact though confined ſenſe; and conſidered as comprehending its adjuncts, the ſtudy of it is very important. It leads the mind beyond the narrow ſphere of its own obſervation, enlarges its comprehenſion, and weakens its prejudices; it forms an intereſting link between mere ſenſation and abſtract ſpeculation; it raiſes the mind above the former, and cultivates and ſtores it for the latter. Here, however, it obviouſly borrows its principal utility from what rather comes under the head of civil or natural hiſtory, or of natural and mental philoſophy.

Natural hiſtory, in its various branches, being principally concerned about things, is well adapted for the early ſtage of mental culture. The ſtudy of it forms habits of obſervation, of attaching diſtinct conceptions to words (and conſequently of uſing words correctly), of claſſification, and of attention to objects not connected with ſelf. In all the ſtages of mental culture, theſe ends are anſwered; it gives additional intereſt to ſurrounding objects, and leads us to view them as the works of the great Author of nature. We muſt add here the words of one of our ableſt naturaliſts, in his introduction to his favourite ſcience. "I would recommend botany for its own ſake. I have often alluded to its benefits as a mental exerciſe, nor can any exceed it in raiſing curioſity, gratifying a taſte for beauty and ingenuity of contrivance, or ſharpening the powers of diſcrimination. What, then, can be better adapted for young perſons? The chief uſe of a great part of our education is no other than what I have juſt mentioned. The languages and the mathematics, however valuable in themſelves when acquired, are even more ſo as they train the youthful mind to thought and obſervation. In Sweden, natural hiſtory is the ſtudy of the ſchools by which men riſe to preferment; and there are no people with more acute or better regulated minds than the Swedes."

Mathematical ſcience forms a higher ſtep in the gradation of mental culture. The loweſt branch of it is arithmetic. Learnt merely as an art, it is not without its utility in the culture of the mind. We, however, conſider it as more comprehenſively ſtudied, or rather as *taught* with further views. The commencement of habits of clear perception, of abſtraction, of regularity and correctneſs in practice, of acuteneſs, of uſing definite means in order to obtain definite ends, and of acting upon general rules, may reaſonably be expected from the proper mode of learning this ſcience. It then becomes an introduction to ſcientific inveſtigation; and in this view it is peculiarly valuable, from the exact arrangement of our notation, and the certainty of the reſults of our operations. Algebra poſſeſſes nearly the ſame advantages, and in addition to them, others more important to a higher degree of mental culture. It generates the power of invention and combination, and it accuſtoms the mind to general reaſoning, at the ſame time leaving it the power to check and correct that reaſoning at every ſtep. Geometry forms a habit of clear and cautious reaſoning. It ſerves as a corrective to the wild flights of imagination, and gives proportional vigour to the judgment. The higher branches of mathematical ſcience reſemble, in their effects upon the mind, the one of theſe elementary branches which they moſt reſemble in their mode of inveſtigation. "If there were nothing valuable in the mathematical ſciences for the uſes of human life, yet they are well worth our ſtudy; for by perpetual examples they teach us to conceive with clearneſs, to connect our ideas in a train of dependance, to reaſon with ſtrength and demonſtration, and to diſtinguiſh between truth and falſehood. Something of theſe ſciences ſhould be ſtudied by every one; and that, as Mr. Locke expreſſes it, not ſo much to make us mathematicians, as to make us reaſonable creatures."

Another ſource of the utility of the mathematics, is their ſubſerviency to natural philoſophy. To deſcribe the phenomena of the univerſe, to inveſtigate their cauſes and the connection of theſe cauſes, are the principal objects of this ſcience. To mention theſe objects, is nearly all which is neceſſary to indicate its valuable effects on the mind. The habits of accurate and perſevering obſervation, of inveſtigation, of abſtraction, and of correct reaſoning, are more or leſs produced and cultivated by the ſtudy of the philoſophy of nature. It furniſhes abundant ſcope for the moſt ſublime ſpeculations, and calls forth the nobleſt exerciſes of the imagination, yet reſtrains the mind within the limits of reality. It carries us beyond the boundaries of ſenſe, and leſſens our intereſt in ſelf by increaſing our concern with every thing around us. It enlarges the comprehenſion of the ſoul; for it offers for contemplation the laws of the univerſe. It prepares the ſtudent for an acquaintance with the human mind; for the ſtrictneſs with which its inveſtigations are conducted, prevents that wildneſs of theorizing which is the bane of ſcience, and forms the habit of cautiouſly attending to phenomena, in order to aſcertain the general laws which regulate them. It aids the cauſe of religion; for it accuſtoms the mind to ſeek for the cauſes of obſerved appearances, and leads it from deſign and regularity to infer an intelligent Firſt Cauſe.

Hiſtory produces or cultivates the habit of purſuing with accuracy a ſeries of connected events or phenomena; of tracing cauſes from effects, and of obſerving the operation of cauſes, either ſingly, or in their various combinations. The ſtudent is concerned about realities, and his judgment is corrected; the web he contemplates is not unfrequently intricate, and his penetration is exerciſed in unfolding it. He obſerves the ſlow operation of moral cauſes, and he learns patience as to the reſult of his exertions for the good of others; he ſees the efficacy of minute cauſes operating in conjunction with prediſpoſing circumſtances, and he learns prudence in the direction of thoſe exertions. The enlightened ſtudy of hiſtory prevents the formation, or promotes the eradication of thoſe prejudices which narrow the comprehenſion of the mind. "There is ſcarce any folly or vice," ſays lord Bolingbroke, "more epidemical among the ſons of men, than that ridiculous and hateful vanity, by which the people of each country are apt to prefer themſelves to thoſe of any other, and to make their own cuſtoms, and manners, and opinions, the ſtandard of right and wrong, of true and falſe." This preſents an effectual bar to improvement in the great ſocial concerns of man; and it is apt, perhaps neceſſarily ſo, to be accompanied with contracted views of the qualities of thoſe who differ from us in their religious or political ſentiments. Now what in one caſe deſtroys the illuſion tends to diſſipate it in the other. He who has learnt to view the qualities and actions of other nations as not to be deſpiſed becauſe unlike thoſe of his own, places himſelf out of his little narrow ſphere of ſelf, and gains a comprehenſive habit of thought, which will prevent him from refuſing to admire thoſe qualities and actions, which can ſtand the teſt of reaſon, in bodies of men, or in individuals who differ from him in their modes of thinking. The ſtudy of hiſtory is well adapted to the cure of thoſe prejudices. Accuſtomed to contemplate the hiſtory of other nations, to view them in their mutual dependencies and connections, for a time to make their intereſts our own, we learn to regard the community of which we form a part as itſelf a part of a ſtill greater community, and without becoming indifferent to its welfare and its excellencies, we acquire the power of diſcerning the value of opinions and practices which are of foreign growth.

The ſtudy of compoſition derives its value, partly from facilitating our own practice, and partly from putting it in our power, more fully to feel and to appreciate the beauties of the beſt authors. The practice of compoſition is highly valuable, becauſe it enables us to benefit others by our mental attainments; to judge of the extent and ſolidity of thoſe attainments; to command our knowledge; and to make that knowledge clear and ſubſtantial. Habits of correct compoſition are almoſt neceſſarily productive of preciſion in our ideas, of perſpicuity in our reaſonings; they prevent their poſſeſſors from reſting ſatisfied with ſuperficial notions; and they force them to think cloſely.

The higheſt ſcientific object to which the young can be directed, and what indeed ſhould form the laſt art of education, is mental philoſophy, or the philoſophy of the human mind, that ſcience which teaches us the laws of our mental frame, which ſhews us the origin of our various modes and habits of thought and feeling, how they operate upon one another, and how they are cultivated or repreſſed. The well directed ſtudy of it calls into action and improves the higheſt intellectual faculties; and while it employs the powers of the mind, it ſuggeſts the beſt means for their culture, and the beſt mode of their direction. It enables us to trace the intricacies of our own hearts, and points out the proper diſcipline for their correction. It diſcovers to us the real excellencies of the mind, and guides us in our efforts for the attainment of them. To ſucceſs in forming the moral and mental character of others, it is more or leſs eſſential; for it diſcloſes the nature of our influence over their minds, and the beſt mode of exerciſing it ſo as to bring their various faculties into the beſt adjuſted and moſt perfect ſtate. Purſued with proper views, and in a proper manner, it lays the beſt foundation for the higheſt degrees of intellectual, moral, and religious improvement. "There are difficulties," to uſe the words of the great Hartley, "both in the word of God, and in his works; and theſe difficulties are ſometimes ſo magnified, as to lead to ſcepticiſm, infidelity, or atheiſm. Now the contemplation of our own frame and conſtitution, appears to me to have a peculiar tendency to leſſen theſe difficulties attending natural and revealed religion, and to improve their evidences, as well as to concur with them in their determination of man's duty and expectations."

The beſt ground-work for the purſuit of mental ſcience is, an accurate judgment, a diſcriminating, penetrating intellect, and a habit of correct and cautious reaſoning; and therefore the beſt preparatory culture of mind is the ſtudy of the various branches of the mathematics and of natural philoſophy. But habits of reflection, and good ſenſe, are all which is eſſential to the beneficial purſuit of mental ſcience; and with theſe, it will in all caſes lead to reſults highly important to individual welfare and uſefulneſs. The young in particular will be led, by an acquaintance with the practical laws of the mind, to perceive how their preſent conduct affects their future character and happineſs; to perceive the importance of avoiding a frivolous employment of their time without any end beyond mere amuſement; to perceive the impoſſibility of indulging in vicious gratifications without leſſening their means of happineſs, and checking their progreſs towards excellence. They will learn how habits are formed, almoſt imperceptibly, and, when long exerciſed, how exceedingly difficult it is to eradicate them; they will learn to conſider the formation of habits, as requiring, therefore, their utmoſt circumſpection. They will be enabled to diſcern what habits of thought and feeling are baneful, what uſeful; what means of happineſs ſhould be regarded as of primary value, what ſhould be regarded as ſecondary only. In ſhort, there can be no heſitation in affirming, that, next to the immediate purſuits of religion, to which the laws of the mind direct, a judicious acquaintance with thoſe laws is the moſt important means for the right employment of that period of life on which the happineſs of our exiſtence in a great meaſure depends.

INTELLECTUAL *Thinking.* See THINKING.

INTELLIGIBLE, any thing capable of being underſtood, or conceived, by the mind.

Philoſophers have invented certain beings which are purely intelligible, and only ſubſiſt in the underſtanding: ſuch are the *entia rationis*, univerſal ideas, and other chimeras.

The intelligible, or intellectual world, is the idea of the world in the divine mind, frequently ſpoken of by Malebranche.

INTEMPERIES, in the *Galenical* and *Humoral Pathology*, the ſame with *dyſcraſy*, δυσκρασια, and the oppoſite of *temperament*, or κρασις, *craſis*. As health was ſuppoſed to conſiſt in the proper temperament, or proportion of the four qualities of hot and cold, dry and moiſt; ſo the *intemperies*, or diſproportionate prevalence of any one or two of theſe qualities, or of the four humours, in which they were ſuppoſed to be particularly inherent, was deemed the origin of all diſeaſes: and according to the ſuppoſed predominance of this or that quality or humour, each morbid intemperies received its name. Thus when heat or bile prevailed, it was called *intemperies calida*, or biliosa; when cold and phlegm, *intemperies frigida*, and pituitoſa; and ſo on. (See Sennert. Inſtit. Medicinæ, lib. ii. cap. 3.) See Humoral *Pathology*, and Galen.

INTENDANT, one who has the conduct, inſpection, and management of any thing.

This is a title frequent among the French: they have intendants *of the marine*, who are officers in the ſea-ports, whoſe buſineſs is to take care the ordinances and regulations relating to ſea-affairs be obſerved; intendants *of the finances*, who have the direction of the revenues; intendants *of provinces*, who are appointed by the king to take care of the adminiſtration of juſtice, policy, and finances, in the provinces; alſo, intendants *of buildings*, *of houſes*, &c.

INTENDMENT *of Law*, the ſenſe, intention, or true meaning of the law.

The judges ought to judge according to the common intendment of the law.

Intendment *of Crimes*. In caſes of treaſon, intention proved by circumſtances is puniſhable as if it were put in execution. So likewiſe, if a perſon enter the houſe in the night-time, with intent to commit burglary, it is felony: and an aſſault on the high-way, with an intent to commit burglary, is felony, and puniſhed with tranſportation, 23 Car. II. c. 1. 7 Geo. II. c. 21.

INTENSIO, *Lat.* Intenso, *Ital. Intenſe*, in *Muſic*. Intenſe ſounds are ſuch as are produced with the greateſt force, which are loudeſt, and heard at the greateſt diſtance. They are ſuch ſounds likewiſe, as are produced from ſtrings of greateſt tenſion, and which, on that account, vibrate more powerfully.

INTENSION is a term frequently uſed by the Greek and other ancient writers on muſic: intenſions of the gravitas, were the major harmonics of the aſcent, in the deſcending major ſcale of the gravitas, according to M. Overend's Manuſcripts in the library of the Royal Inſtitution, vol. vi. p. 7. alſo, vol. ii. p. 213. in which volumes much information on this curious, but almoſt obſolete ſubject, will be found.

INTENSIONE, in *Law*, a writ which lies againſt him who enters after the death of the tenant in dower, or tenant for life, and holds out him in the reverſion, or remainder.

Intensione, *Ital.* as *prima intenſione*, in *Muſic*, as well as painting, implies a *ſketch*, a ſubject, a firſt deſign.

INTENSUM Diatonum. See Diatonic and Genus.

INTENT, in *Civil Law*, ſignifies to begin or commence an action, or proceſs.

INTENTION, or Intension, in *Medicine*, that judgment or method of cure, which a phyſician forms to himſelf from a due examination of the ſymptoms.

Intention, in *Phyſics*, the increaſe of the power, or energy, of any quality; as heat, cold, &c.

By which it ſtands oppoſed to *remiſſion*; which ſignifies its decreaſe, or diminution.

Intention, in *Metaphyſics*, denotes an exertion of the intellectual faculties with more than ordinary vigour; when the mind with earneſtneſs fixes its view on any idea, conſiders it on all ſides, and will not be called off by any ſolicitation.

The ſchoolmen alſo ſpeak of terms of firſt and ſecond intention.

Intention, *a Term of Firſt*, is that which ſignifies a thing; the primary deſign of men, in eſtabliſhing words, being to expreſs things, or the ideas they have of things.

Intention, *a Term of Second*, is that which does not ſignify a thing, but another term, or ſign.

Thus, a tree, a man, &c. are terms of *firſt* intention; and the terms in rhetoric, grammar, &c. as figure, kind, &c. are terms of *ſecond* intention.

Intention, *Intentio*, επιτασις, in the *Ancient Muſic*, was uſed to denote the paſſage of the voice from grave to acute.

INTENTIONAL Qualities. See Qualities.

INTER *Canem et Lupum*, in *Law*, words uſed formerly in appeals, to ſignify that a crime was committed in the twilight, i. e. *inter diem et noctem*, &c. This part of a day has divers other denominations: thus, in ſome parts of England, they call it *mock-ſhadow*, corruptly *muck-ſhade*: and, in the north, *day-light's gate*; others ſay, *betwixt hawk and buzzard*.

INTERAMNA, or Interamnium, (*Teramo*,) in *Ancient Geography*, a town of Italy, ſituated in Latium, very near Campania, on the river Nar, which, from its ſource to its mouth, ſerved as a boundary between the countries of the Sabines and Umbrians.

INTERCALARY Day, denotes the odd day inſerted in the leap year. See Bissextile.

The word is derived from the Latin *intercalaris*, of *calo*, *calare*, which anciently ſignified, *to call with a loud voice*: an intercalary day, among the Romans, ſignifying a day inſerted between two other days; which, for that reaſon, was proclaimed by the prieſts with a loud voice.

INTERCALATION. See Interpolation.

INTERCAPSULARIA, in *Anatomy*, a name given by ſome writers to the cavities between the ſcapulæ and the vertebræ.

INTERCEPTED Axis, in *Conic Sections*, is the ſame with what is otherwiſe called the *abſciſſa*.

INTERCESSION, Intercessio, was uſed in *Ancient Rome*, for the act of a tribune of the people, or other magiſtrate, by which he inhibited the acts of other magiſtrates; or, even, in caſe of the tribunes, the decrees of the ſenate. *Veto* was the ſolemn word uſed by the tribunes when they inhibited any decree of the ſenate, or law propoſed to the people. The general law of theſe interceſſions was, that any magiſtrate might inhibit the acts of his equal, or inferior; but the tribunes had the ſole prerogative of controlling the acts of every other magiſtrate, yet could not be controlled themſelves by any.

INTERCESSOR, from *inter* and *cedo*, *I go between*, a perſon who prays, expoſtulates, or intercedes, in behalf of another.

In the Roman law, interceſſor was the name of an officer, whom the governors of provinces appointed principally to raiſe taxes, and other duties.

Intercessor is alſo a term heretofore applied to ſuch biſhops as, during the vacancy of a ſee, adminiſtered the biſhopric, till a ſucceſſor to the deceaſed biſhop had been elected. See Bishop.

The third council of Carthage calls theſe *interventors*.

INTERCIDENT Pulse, a term uſed by medical writers to expreſs a ſort of pulſe, in which between two regular ſtrokes there is perceived a third irregular.

INTERCOLUMNIATION, or Intercolumnation, in *Architecture,* ſignifies the ſpace between two columns. See the plan of *Baſilic,* in *Plate Architecture.*

Vitruvius calls it *intercolumnium;* which, according to that author, is of five kinds: viz. *picnoſtyle,* A, one diameter and a half; *ſiſtyle,* B, two diameters; *euſtyle,* C, two and a quarter diameters, which is the moſt graceful; *diaſtyle,* D, three diameters; and *aræoſtyle,* E, four diameters; which ſee explained under their proper heads, Picnostyle, &c. The intercolumniation, or ſpace between the columns to the arcade F, is ſeven and a half diameters; and the intercolumniation wherein there is a ſpace, G, of only one half a diameter, is called coupling columns, an invention aſcribed to the moderns.

From a medium, ſome authors have laid down the following proportions; in the Tuſcan order, the intercolumniation, is to be four diameters of the body of the column below; in the Doric, three; in the Ionic, two; in the Corinthian, two one quarter; and in the Compoſite, one and a half.

INTERCOMMONING is when the commons of two manors lie together, and the inhabitants of both have, time out of mind, cauſed their cattle to feed promiſcuouſly in each.

INTERCOSTALES, in *Anatomy,* the muſcles which fill the intervals of the ribs, and are arranged in two ſtrata, diſtinguiſhed by the epithets of *external* and *internal.* This region of the body includes alſo the levatores coſtarum and triangularis ſterni.

The intercoſtal muſcles (intercoſtiens) conſiſt of two thin muſcular planes in each of the intercoſtal intervals, having their fibres diſpoſed obliquely, and attached to the margins of the ribs, which bound theſe ſpaces.

The *external intercoſtal* muſcles are attached by their upper edges to the outer border of the lower margins of the ribs, by means of tendinous and fleſhy fibres. Their fibres are directed obliquely downwards and forwards; and they are attached below by an inſertion exactly reſembling the former to the upper edge of the ſucceeding rib. Various blood-veſſels and nerves penetrate them in different parts of the trunk. Their origin begins at that part of the rib which is articulated to the tranſverſe proceſs of the vertebra, and is continued towards the front as far as the junction of the bone with the cartilage: beyond this point the intervals of the cartilages are filled with their aponeurotic fibres, which have ſimilar attachments and direction to the external intercoſtal muſcles.

As the fibres of theſe external intercoſtal muſcles paſs from above obliquely downwards and forwards, they form towards the front acute angles with the upper and obtuſe angles with the lower ribs. The poſterior fibres are more oblique than the anterior. The ſtratum placed under the firſt rib, between it and the ſecond, is called the firſt intercoſtal muſcle; and thoſe of the following intervals, according to the order in which they ſucceed, the ſecond, third, &c. to the eleventh.

The external intercoſtal muſcles are covered on their outer ſurfaces by moſt of the broad muſcles of the trunk, as the two pectorals, obliquus externus abdominis, ſerratus anticus, and the ſerrati poſtici; and in ſome degree behind by the ſacrolumbalis and longiſſimus dorſi. They correſpond on the internal ſurface to the internal intercoſtals, from which they are partly ſeparated by the intercoſtal veſſels and nerves. Near the vertebral column they are covered by the pleura.

The *internal intercoſtal* muſcles exactly reſemble the former in ſituation, attachments, and number. They commence behind at the angles of the ribs, and extend in front to the ends of the cartilages. They are attached to the inner borders of the edges of the ribs; and their fibres proceed in an oblique courſe from above downwards and backwards, ſo as to decuſſate thoſe of the external ſtratum. They form thinner ſtrata than the external intercoſtals, are more tendinous, have their fibres leſs oblique and conſequently rather ſhorter. Sometimes a faſciculus of one or two of the internal intercoſtals paſſes over one rib to be fixed into the ſecond. Theſe are very irregular in number, ſize, and ſituation, and do not require a ſeparate deſcription: they have however been noticed as diſtinct muſcles by the name of *ſubcoſtales.*

As the external intercoſtals only reach to the ends of the bony portions of the ribs, and the internal do not extend beyond the angles, a ſmall part of the intercoſtal intervals in front and behind is filled only by a ſingle ſtratum of fibres; but the remaining and largeſt part is cloſed by two layers.

The internal intercoſtal muſcles are covered by the external, from which they are partly ſeparated by the veſſels and nerves of the ſame name. Where the former end in front, the latter are covered by the thin aponeuroſis already deſcribed. They are lined on the inſide by the pleura.

The *levatores coſtarum* (les tranſverſo-coſtiens) are ſmall, thin, and flat faſciculi of a radiated form, placed behind the external intercoſtals, from which they are very diſtinct. They are twelve in number, as each rib has one. Each of theſe muſcles has an aponeurotic origin from the apex of the tranſverſe proceſs of the correſponding dorſal vertebra, or from the ligament connecting the rib to that proceſs; its fibres paſs obliquely downwards and forwards, and, growing broader, are attached to the upper edge of the rib immediately below. The levator of the firſt rib ariſes from the tranſverſe proceſs of the ſeventh cervical vertebra, that of the ſecond from the correſponding proceſs of the firſt dorſal vertebra, and ſo on to the twelfth. They increaſe in ſize regularly from above downwards.

Beſides theſe, each of the two, three, or four lower ribs has a longer faſciculus, ariſing from the tranſverſe proceſs of the ſecond vertebra above it. Theſe are called levatores longiores, to diſtinguiſh them from the former, which are named breviores. They have thin tendinous origins from the tranſverſe proceſſes, paſs over the ribs immediately below theſe proceſſes, and are inſerted into the upper borders of the ſucceeding ribs: thus the firſt levator longior, ariſing from the tranſverſe proceſs of the ſeventh dorſal vertebra, is fixed to the ninth rib.

Theſe muſcles are placed between the external intercoſtals and the ſacrolumbalis and longiſſimus dorſi.

The *triangularis ſterni* (ſterno-coſtalis, ſterno-coſtien) is a very thin flattened ſtratum, of a triangular figure, placed behind the cartilages of the ribs. It is fixed to the poſterior part of the edges of the enſiform cartilage, and of the ſecond bone of the ſternum, as high as the cartilage of the fourth rib, by aponeurotic fibres, which cover a conſiderable portion of the muſcle. The fleſhy fibres, directed outwards and upwards, and more oblique as they are nearer to the upper part, form at firſt a continuous broad layer, and then divide into ſeparate portions attached by thin aponeuroſes to the third, fourth, fifth, and ſixth ribs. It is continuous below with the tranſverſus abdominis; correſponds in front to the cartilages of the four laſt true ribs, to the internal intercoſtal muſcles, and to the mammary veſſels; and behind to the pleura, and for a ſmall ſpace to the diaphragm.

The motions produced by the muſcles in this region are the elevation and depreſſion of the ribs, which coincide with inſpiration and exſpiration. The agents of elevation are the levatores and intercoſtal muſcles, beſides other auxiliary powers. The former, fixed to the tranſverſe proceſſes, which are immoveable, can obviouſly exert their action only on the ribs, which they elevate and carry outwards. Thus they increaſe the tranſverſe diameter of the cheſt, particularly at its lower part, where, on one hand, the muſcles are much ſtronger, and on the other, in conſequence of the greater mobility of the lower ribs, the reſiſtance to be overcome is much leſs. The action of the intercoſtals in elevating the ribs is much favoured by the mode of attachment of the firſt and ſecond of theſe bones. They poſſeſs but little power of motion, and therefore form a fixed point, to which the others can be elevated. They are moreover ſtill further fixed, particularly in deep inſpirations, by the ſcaleni, which may carry them in a ſlight degree upwards. Both ſtrata, although the directions of their fibres are ſo different, act equally as elevators: in fact, as the upper part of the cheſt is fixed, the lower portion muſt be moved by theſe powers. In great inſpirations, other muſcles attached to the cheſt, as the pectorales, ſerrati, &c. aſſiſt the levatores and intercoſtal muſcles in elevating and turning outwards the ribs.

The depreſſion of the ribs, or their reſtoration from the elevated to their former ſtate, is nearly a paſſive motion: it depends, in the firſt place, on the relaxation of the elevating powers, and then on the elaſticity of the cartilages connected to the ſternum. Theſe are twiſted in the act of elevation, and immediately recover themſelves when this force ceaſes to act. When the depreſſion is more conſiderable, as in coughing, in difficult expectorations, in ſneezing, caſes in which a ſtrong exſpiration is required for the purpoſe of expelling much air from the cheſt, an active power is exerted for drawing down the ribs. The triangularis ſterni, which has its fixed point in the ſternum, depreſſes the cartilages of the true ribs. The abdominal muſcles fix below the looſe edges of the falſe ribs, which thus become a fixed point to which the other ribs may be depreſſed by the intercoſtal muſcles. Thus the latter muſcles are elevators or depreſſors, according as the fixed point is above or below. Moreover, the quadratus lumborum holds down firmly the laſt rib; and bears the ſame relation to that bone in great exſpirations, which the ſcaleni do to the two firſt ribs in deep inſpirations. The ſerratus inferior poſticus aſſiſts the abdominal muſcles on theſe occaſions.

The intercoſtal muſcles and the diaphragm ſeem to form an exception to that general law of the voluntary muſcles, by virtue of which, any muſcle after long exerciſe goes into a ſtate of fatigue, requiring for the reparation of its power an intermiſſion of action, which may be particularly obſerved in ſleep. Now the motions of the cheſt, beginning and ending with life, are never interrupted. This exception is only apparent; each contraction is ſucceeded by a proportionate relaxation, ſo that the time of inactivity of the pectoral muſcles equals that of their active ſtate. Moreover, the diaphragm and intercoſtals mutually ſupply each other's places; both are ſaid to be employed in inſpiration, but ſometimes one and ſometimes the others are more actively concerned; ſo that we may conſider them in ſome degree as alternately acting and reſting. The intercoſtals appear to be the moſt concerned during ſleep, and the diaphragm in the waking ſtate. Indeed a conſiderable contraction of the latter, in ſome meaſure, oppoſes that of the lower intercoſtals, ſince it tends to contract the lower circumference of the cheſt which the others enlarge. The two ſtrata of the intercoſtals may contract ſeparately; thus one may reſt while the other is employed. Laſtly, the levatores may alternate with the latter muſcles: thus, although the motions of the cheſt are conſtant, their agents, like all the other muſcles of the animal life, may be ſubjected to the law of intermiſſion of action. Hence, if reſpiration is conſiderably hurried, and all the inſpiratory muſcles are brought into action, they are affected with a real laſſitude, and at laſt cannot contract without difficulty. In running, where the blood is carried in great abundance to the heart, and muſt paſs quickly through the cheſt, we ſoon loſe breath; which is merely experiencing a difficulty in contracting the tired muſcles of inſpiration. Reſpiration is then interrupted, as locomotion would be by a fatigued ſtate of the muſcles of the lower extremities; and this may even go ſo far as to produce a real immobility of the inſpiratory muſcles, a ſtate, which though not dangerous in other inſtances, as in the organs of locomotion for example, is fatal in the reſpiratory muſcles as it ſuſpends breathing. Examples of animals, and even of men falling ſuddenly dead after great exertions in running, are not extremely rare. Death occurs in theſe inſtances, as when the phrenic nerve or the ſpinal marrow is divided. Thoſe affections of the cheſt, in which reſpiration is hurried for a certain time, occaſion at laſt a real laſſitude of the pectoral muſcles; and the difficulty of breathing produced by this tired ſtate of the moving organs, ſucceeding to that produced by the diſeaſe itſelf, prolongs the painful ſenſation of ſuffocation. We muſt diſtinguiſh, in theſe caſes, what belongs to the lung, from that which ariſes from the muſcles. After certain hyſterical attacks, in which the diaphragm and intercoſtal muſcles have been violently agitated, a real ſenſe of fatigue is experienced in the cheſt, which can only be moved with difficulty, and not to a ſufficient extent for the production of loud ſounds, a phenomenon which may be obſerved alſo after exertion in running. The muſcles require reſt before they can expel air in a quantity capable of producing ſtrong and diſtinct ſounds.

INTERCOSTALES *Arteriæ*, arteries which run in the intervals of the ribs: the intercoſtales venæ are veins correſponding to thoſe. See ARTERY and VEIN.

INTERCOSTALES *Nervi*, are the branches of the ſpinal marrow in the back, which accompany theſe arteries and veins. The epithet *intercoſtales* is ſometimes alſo applied to the great ſympathetic nerve. See NERVE.

INTERCUS, a word uſed by ſome medical writers, to expreſs that ſort of dropſy more uſually called an *anaſarca*.

INTERDICT, a cenſure inflicted by a pope, or biſhop, ſuſpending the prieſts from their functions, and depriving the people of the uſe of ſacraments, divine ſervice, and Chriſtian burial.

In common law, interdict is alſo uſed in the ſame ſenſe as in the canon law; where it is defined to be, "cenſura eccleſiaſtica prohibens adminiſtrationem divinorum."

INTERDICT is moſt properly underſtood of a general excommunication of a country, or city, as appears by the Decretals. See EXCOMMUNICATION.

There is a *local* and a *perſonal* interdict: where theſe two are joined, the interdict is ſaid to be *mixed*.

This puniſhment, as well as general excommunications, were but little known till the time of pope Gregory VII. In the year 1169, pope Alexander III. put all England under an interdict, forbidding the clergy to perform any part of divine ſervice, except the baptizing of infants, taking confeſſion, and giving abſolution to dying penitents.

In excommunicating a prince, all his adherents, that is, his ſubjects who retain their allegiance, are excommunicated, and the whole country is put under an interdict. In the reign of king John, the kingdom of England lay under a papal interdict, for above ſix years together: it began A. D. 1208.

In imitation of the popes, the biſhops alſo ſoon began to interdict; and it became a common thing for a city, or town, to be excommunicated for the ſake of a ſingle perſon whom they undertook to ſhelter; but this ſeverity was found to have ſuch ill effects, that they have been obliged to moderate it.

An interdict is denounced, and taken off again, with the ſame formalities as an excommunication.

INTERDICTS, in the *Roman Law*, certain formulæ of words by which the prætor, when the poſſeſſion of any thing was conteſted between many, ordered or forbade ſomething to be done with it, till the right or property ſhould be legally determined.

Which formulæ were called interdicts, becauſe they related to the poſſeſſion of the thing in the interim, or till the right was aſcertained.

They had three kinds of interdicts, *prohibitory*, *reſtitutory*, and *exhibitory*. *Prohibitory*, were thoſe by which the judges forbade any one to vex another in the poſſeſſion of any thing legally belonging to him. *Reſtitutory* were thoſe by which the judges appointed any one, who had been expelled out of his eſtate to be repoſſeſſed, before his right was legally aſcertained; and this was the ſame with what they called the *reintegrant*. *Exhibitory* were thoſe by which any thing in diſpute was ordered to be exhibited; as a teſtament, &c.

There was alſo a ſecond diviſion of interdicts; *viz.* into *adipiſcendæ*, *retinendæ*, and *recuperandæ:* the firſt tending to the acquiring a new poſſeſſion, as the *interdict quorum bonorum*, &c., the ſecond to the keeping an old one till it was farther determined, as the *uti poſſidetis*, &c., the laſt to the recovering one loſt, as *unde vi*, &c.

INTERDICTION *of Water and Fire*, a ſentence anciently pronounced againſt ſuch as, for ſome crime, were to be baniſhed.

They were not directly adjudged to baniſhment; but by giving order, that nobody ſhould receive them, but deny them *fire and water*, they were condemned, as it were, to a civil death: and this they called *legitimum exilium*. Livy. See EXILE.

INTEREST, a ſum of money reckoned for the loan and forbearance of ſome other ſum, lent for, or due at, a certain time, according to ſome certain rate.

The ſum lent, or forborn, is called the *principal*, becauſe it is the ſum that procreates the intereſt, or from which the intereſt is reckoned.

Intereſt is either *ſimple* or *compound.*

INTEREST, *ſimple*, is that counted from the principal only.

Let p repreſent the principal, n the number of years or parts of a year, r the intereſt of 1*l.* for a year, and m the amount of the principal p for the time n at the rate r; and ſince the amount of 1*l.* for one year is $1 + r$, the amount of 1*l.* for n years, muſt be $1 + nr$; the intereſt of the principal p at the rate r in n years muſt be pnr; and $1l. : 1 + nr :: p : p + pnr = m$ the amount: from this general theorem we can eaſily deduce problems for reſolving all the caſes that occur in ſimple intereſt.

Prob. 1.—Having any principal ſum, and time, and rate of intereſt given, to find the amount: as $m = p + pnr = p \times \overline{1 + nr}$; we ſhall have this rule: multiply the intereſt of 1*l.* for a year by the given number of years. Add unity to the product and multiply the ſum by the given principal: this ſecond product will be the amount required. *E. g.* what ſum will 567*l.* 10*s.* amount to in nine years at 5 *per cent. per annum?* Here $p = 567.5$, $n = 9$, and $r = .05$; therefore $m = p \times \overline{1 + nr} = 567.5 \times \overline{1 + .45} = 822.875 =$ 822*l.* 17*s.* 6*d.* Or if it were required to find the amount of one penny at 5 *per cent.* ſimple intereſt in 1780 years; $p =$ 1*d.*, $n = 1780$, and $r = .05$, therefore $m = 1 \times \overline{1 + 89} = 90$ *d.* = 7*s.* 6*d.*

If the time given does not conſiſt of whole years the fractional part may be eaſily reduced to decimal parts of a year.

Prob. 2.—Having the amount of any principal at a given rate in a given time, to find the principal; it appears, from the theorem, $m = p \times \overline{1 + nr}$, that $p = \frac{m}{1 + nr}$; *i. e.* divide the amount by the product of the time and intereſt of 1*l.* for a year with unity added to it. *E. g.* what principal will amount to 822*l.* 17*s.* 6*d.* in nine years at 5 *per cent. per annum?* Here $m =$ 822*l.* 17*s.* 6*d.* or 822.875, and n, r as before: therefore $\frac{m}{1 + nr} = \frac{822.875}{1 + .45} = 567.5$, or 567*l.* 10*s.*

Prob. 3.—Having the amount of a given principal at a given rate, to find the number of years. From the theorem we eaſily deduce, by tranſpoſition and diviſion, $n = \frac{m - p}{pr}$, *viz.* ſubtract the principal from the amount, and divide the remainder by the product of the principal and intereſt of 1*l.* for a year. *E. g.* in what time will 567*l.* 10*s.* amount to 822*l.* 17*s.* 6*d.* at 5 *per cent. per annum?* $n = \frac{m - p}{pr} = \frac{822.875 - 567.5}{28.375} = \frac{255.375}{28.375} = 9$.

Prob. 4.—Having the amount of a given principal in a given time, to find the rate, and conſequently the intereſt *per cent.* From the theorem we eaſily derive $r = \frac{m - p}{pn}$; *i. e.* ſubtract the principal from the amount, and divide by the product of the principal into the number of years; *e. g.* at what rate *per cent.* will 567*l.* 10*s.* amount to 822*l.* 17*s.* 6*d.* in nine years? Here $\frac{m - p}{pn} = \frac{822.875 - 567.5}{5107.5} = \frac{255.375}{5107.5} = .05$: and, therefore, the intereſt is 5 *per cent.*

Prob. 5.—The annual intereſt of any principal p at the rate r, is pr; *i. e.* multiply the principal by the intereſt of 1*l.* for a year, *e. g.* the intereſt of 75*l.* for one year at 3 *per cent.* is $75 \times .03 = 2.25 =$ 2*l.* 5*s.* The intereſt of 157*l.* 17*s.* 6*d.* at 5 *per cent.* is 157.875 (reducing the 17*s.* 6*d.* to decimals of a pound) $\times .05 = 7.89375 =$ 7*l.* 17*s.* 10½*d.* The intereſt of any principal p at the rate r for n years, is prn; obtained by multiplying the principal, rate, and number of years.

The daily intereſt is found by dividing the annual intereſt by 365; thus .05, being the intereſt of one pound for one year at 5 *per cent.*, divided by 365, the quotient will be .0001369, &c. which is the intereſt of one pound for one day at the ſame rate. And $\frac{.03}{365} = .0000821$ is the intereſt of one pound for one day, at 3 *per cent. per annum.* The intereſt for one day, at any rate, being thus found, that intereſt multiplied by 2, 3, 4, 5, 6, &c. gives the intereſt of one pound for any number of days; and thus the following table of ſimple intereſt for any number of days is eaſily made.

INTEREST.

A TABLE

Of Simple Intereſt.—The Intereſt of One Pound for any Number of Days, &c.

Days.	3 per cent.	3½ per cent.	4 per cent.	4½ per cent.	5 per cent.	Days.
1	.0000,821	.0000,958	.0001,095	.0001,232	.0001,369	1

22	.66	.77	.88	.99	1.1	22
23	.69	.805	.92	1.035	1.15	23
24	.72	.84	.96	1.08	1.2	24
25	.75	.875	1.	1.125	1.25	25

The Uſe of the preceding Table.—When the intereſt of any ſum of money is required for any number of days, look in the table for the number of days, and even with that number, under the given rate of intereſt, will be found the intereſt of one pound, for that time, and at that rate; which intereſt, ſo found, being multiplied by the principal ſum, the product anſwers the queſtion.

Example.—What is the intereſt of 462*l.* for 85 days, at 5 *per cent. per annum?*

In the table, even with 85 days, and under 5 *per cent.*, you find the intereſt of 1*l.* to be .0116,438.

Which multiplied by the principal 462, the product will be 5*l.* 7*s.* 7*d.*

N.B. If the principal ſums contain ſhillings and pence, you muſt reduce them into decimal parts, and multiply accordingly.

When the intereſt of any ſum is required for a number of years and days together, as it frequently happens upon paying off a bond or mortgage, add the intereſt of one pound for the years at the end of the foregoing table, to the intereſt of one pound for the odd days; multiply that by the principal ſum, and the product will anſwer the queſtion.

By the aſſiſtance of the following table the intereſt of any ſum of money may be obtained, from a million to a pound, for any number of days, at any rate of intereſt.

the intereſt required. See Smart's Tables. Ferguſon's Tracts, &c. For the method of calculating annuities, ſee ANNUITIES.

INTEREST *Compound,* is that which is counted both from the principal, and the ſimple intereſt forborn; called alſo *intereſt upon intereſt.*

Compound intereſt ariſes from the principal and its intereſt put together, as that intereſt becomes due. To find this, it is neceſſary to find the new principal, which is ſtill created by the increaſe of the growing money, at the ſeveral times when the payments of intereſt were due.

Although it be not lawful to lend money at compound intereſt, yet in purchaſing annuities, penſions, reverſions, &c., it is uſual to allow compound intereſt to the purchaſer for his ready money; and, therefore, it is very neceſſary to underſtand this ſubject. Let *p, r, n,* and *m,* be as before;

and let it be required to find m the amount of the ſum p in n years at the rate r. Now, ſuppoſing the amount of 1*l.* in one year to be $\overline{1+r}$, the amount of the ſame ſum in two years will be $\overline{1+r}|^{2}$; for $1 : \overline{1+r} = \overline{1+r} : \overline{1+r}|^{2}$. In like manner $1 : \overline{1+r} = \overline{1+r}|^{2} : \overline{1+r}|^{3}$ the amount of 1*l.* in three years, and the amount of 1*l.* by the ſame rule in n years will be $\overline{1+r}|^{n}$. Conſequently the amount m of the ſum p in n years will be $p \,.\, \overline{1+r}|^{n}$. From this equation we have $p = \frac{m}{\overline{1+r}|^{n}} \;.\;.\;.\;.\; n = \frac{\log. m - \log. p}{\log. \overline{1+r}}$, and $r = \overline{\frac{m}{p}}|^{\frac{1}{n}} - 1$.

Example. 1.—Let $p = 50 \;.\;.\; \overline{1+r} = 1.04 \;.\;.\; n = 30$, then will m (the amount of 50*l.* in 30 years at 4*l. per cent.*) be $= 50 \times \overline{1.04.}|^{30} = 162$*l.* 17.

Ex. 2.—Let $m = 162$*l.* $17 \;.\;.\;.\; n = 30$ $(\overline{1+r} = 1.04)$, the ſum p will then be $= \frac{162.17}{\overline{1.04}|^{30}} = 50$.

Ex. 3.—Let m, p, and r be reſpectively equal to $162.17 \;.\;.\;.\; 50 \;.\;.\;.$ and $.04$, then will n be $= \frac{2.2099705 - 1.6989700}{.0170333} = 30$.

Ex. 4.—Let m, p, and n be reſpectively equal to $162.17 \;.\;.\;.\; 50 \;.\;.\;.$ and 30, and r will be equal to $\overline{\frac{162.17}{50}}|^{\frac{1}{30}} - 1 = .04$.

As the amount of 1*l.* in n years is $\overline{1+r}|^{n}$, the amount of the ſame ſum in $\overline{n-1}$ years will be $\overline{1+r}|^{n-1}$, in $\overline{n-2}$ years $\overline{1+r}|^{n-2}$, &c.; therefore, if 1*l.* be the amount at the end of the firſt year, the ſeries $1 + \overline{1+r} + \overline{1+r}|^{2} + \;.\;.\;.\;.\;.\;.\; \overline{1+r}|^{n-1}$ will expreſs the amouut of 1*l. per annum* in n years, which may eaſily be found $= \frac{\overline{1+r}|^{n} - 1}{r}$, and m (the amount of the annual ſum a) will be $= \frac{a \,.\, \overline{\overline{1+r}|^{n} - 1}}{r}$, hence a will be $= \frac{m\,r}{\overline{1+r}|^{n} - 1}$, and $n = \frac{\log. \overline{m\,r + a} - \log. a}{\log. \overline{1+r}}$.

In order to find the value of r, let the binomial $\overline{1+r}|^{n}$ be expanded, &c., and $\frac{m}{a\,n}$ will be $= 1 + \frac{n-1}{2}\, r + \frac{\overline{n-1} \,.\, \overline{n-2}}{2 \,.\, 3}\, r^{2} + \text{\&c.}$ and $\overline{\frac{m}{a\,n}}|^{\frac{2}{n-1}} =$ $\overline{1 + \frac{n-1}{2}\, r + \frac{\overline{n-1} \,.\, \overline{n-2}}{2 \,.\, 3}\, r^{2}, \text{\&c.}}|^{\frac{2}{n-1}} = 1 + r + \frac{n+1}{12} \,.\, r^{2}$ nearly. Put $\frac{m}{a\,n} - 1 = c$, and $\frac{6}{n+1} = b$, then will r be $= \sqrt{b\,b + 2\,b\,c} - b$.

Example 1.—If $a = 10 \;.\;.\;.\; n = 10 \;.\;.\;.\; \overline{1+r} = 1.04$, m will be $= \frac{\overline{1.04}|^{10} - 1}{.04} = 120.06$*l.*

Ex. 2.—Let n and $\overline{1+r}$ be the ſame as above, and $m = 120.06$, then will $a = \frac{120.06 \times .04}{\overline{1.04}|^{10} - 1} = 10$.

Ex. 3.—Putting $\overline{1+r}$ and $m = 1.04$ and 120.06 reſpectively, and $a = 10$, n will be $= \frac{1.170333 - 1}{.0170333} = 10$.

Ex. 4.—Retaining the ſame values of m and a as in the preceding example, and putting $n = 10$, $c \left(= \overline{\frac{120.06}{100}}|^{\frac{2}{9}} - 1\right)$ will be $= .04146$, $b \left(= \frac{6}{11}\right)$ will be $= .5454$, and r $\left(= \sqrt{.29751 + .04523} - .5454 = .5854 - .5454\right)$ will be $= .04$.

Since $\overline{1+r}$ is the amount of 1*l.* in one year, the converſe of this expreſſion, or $\frac{1}{1+r}$ will be the diſcount of 1*l.* for the ſame time; for if $\overline{1+r}$ to be received at the end of a year is of the ſame value with the preſent payment of 1*l.* by the rule of proportion 1*l.* to be received at the end of a year will be of the ſame value with $\frac{1}{1+r}$ now received, that is, $\overline{1+r} : 1 = 1 : \frac{1}{1+r}$. By the ſame reaſoning $\overline{1+r} : 1 = \frac{1}{1+r} : \frac{1}{\overline{1+r}|^{2}}$ the value of 1*l.* to be received at the end of two years, and hence $\frac{1}{\overline{1+r}|^{n}}$ will be the preſent value of 1*l.* to be received at the end of n years, the value of the ſum a, therefore, to be received at the end of n years will be $\frac{a}{\overline{1+r}|^{n}} = \varpi$; from this equation the value of a will be found $= \varpi \,.\, \overline{1+r}|^{n}$, the value of $n = \frac{\log. a - \log. \varpi}{\log. \overline{1+r}}$, and the value of $r = \overline{\frac{a}{\varpi}}|^{\frac{1}{n}} - 1$.

Example 1.—Let a be $= 20 \;.\;.\; n = 40 \;.\;.\; \overline{1+r} = 1.06$, and $\varpi = \frac{20}{\overline{1.06}|^{40}} = 1.944$.

Ex. 2.—If $\varpi = 1.944$, $\overline{1+r} = 1.06$, and $n = 40$, a $\left(= \overline{1.06}|^{40} \times 1.944\right)$ will be $= 20$.

Ex. 3.—Retaining the values of ϖ and $1 + r$, and putting $a = 20$, n will be $\frac{1.30103 - .2887856}{.0253059} = 40$.

Ex. 4.—If $\varpi = 1.944 \;.\;.\; a = 20$, and $n = 40$, r $\left(= \overline{\frac{20}{1.944}}|^{\frac{1}{40}} - 1\right)$ will be $= .06$.

The value of 1*l.*, payable at the end of n years, being $\frac{1}{\overline{1+r}|^{n}}$, its value at the end of $\overline{n-1}$ years will be $\frac{1}{\overline{1+r}|^{n-1}}$, at the end of $\overline{n-2}$ years $= \frac{1}{\overline{1+r}|^{n-2}}$, and ſo on. It follows, therefore, that the preſent value of the *annual payment* of a for n years will be expreſſed by the ſeries $\frac{a}{1+r} + \frac{a}{\overline{1+r}|^{2}} + \frac{a}{\overline{1+r}|^{3}} \cdots\cdots\cdots + \frac{a}{\overline{1+r}|^{n}} = \frac{a}{r} - \frac{a}{r \,.\, \overline{1+r}|^{n}} = p$; which, therefore, is given when a, n, and r are given. If p, n, r are given, the value of a will be obtained, being $= \frac{pr \,.\, \overline{1+r}|^{n}}{\overline{1+r}|^{n} - 1}$. If a, r, p are given, the value of n will be obtained, being $= \frac{\log.\, a - \log.\, \overline{a - pr}}{\log.\, 1+r}$. In order to find the value of r, when a, p, n are given, let the binomial $\overline{1+r}|^{n}$ in the equation $\frac{a}{r} - \frac{a}{r \,.\, \overline{1+r}|^{n}} = p$, be expanded, &c., and we ſhall have $\frac{p}{na} = 1 - \frac{n+1}{2} r + \frac{\overline{n+1} \,.\, \overline{n+2}}{2 \,.\, 3} r^{2}$, &c.; conſequently $\frac{p}{na}\Big|^{-\frac{2}{n+1}} = \frac{na}{p}\Big|^{\frac{2}{n+1}}$ will be $= \overline{1 - \frac{n+1}{2} r + \frac{\overline{n+1} \,.\, \overline{n+2}}{2 \,.\, 3} r^{2}, \&c.}\Big|^{-\frac{2}{n+1}} = 1 + r - \frac{n-1}{12} r^{2}$ nearly. Let $\frac{na}{p}\Big|^{\frac{2}{n+1}} - 1 = d$, and $\frac{6}{n-1} = b$, then will r be $= b + \sqrt{bb - 2bd}$.

Example 1.—Suppoſing a, n, r to be reſpectively equal to 10, 21, and .05, then will p be $= \frac{10}{.05} - \frac{10}{.05 \times \overline{1.05}|^{21}} = 200 - 71.79 = 128.21$.

Example 2.—Let n, r, and p be reſpectively equal to 21, .05, and 128.21, then will a be $= \frac{.05 \times \overline{105}|^{21}}{\overline{1.05}|^{21} - 1} = \frac{.1393 \times 128.21}{1.78} = 10$.

Example 3.—The quantities r and p being ſtill the ſame and a being equal 10, n will be $= \frac{1 - .5150340}{.0211893} = 21$.

Example 4.—a, p, n being reſpectively equal to 10, 128.21, and 21, r will be equal to $\frac{6}{20} - \sqrt{.06246} = .3 - .25 = .05$.

The following twelve caſes, though they do not ſo frequently occur in practice as the preceding, may not improperly be added here. Let a, as before, be the annuity, n the number of years, m the amount of the annuity in n years, p its value for the ſame time, and r the rate of intereſt.

Caſe 1.—m, p, a being given to find r. In the foregoing caſes m being $= \frac{a \,.\, \overline{1+r}|^{n} - 1}{r}$, and $p = \frac{a \,.\, \overline{1+r}|^{n} - 1}{r \,.\, \overline{1+r}|^{n}}$, $\frac{m}{p}$ therefore will be $= \overline{1+r}|^{n}$, and $p = \frac{\overline{\frac{m}{p} - 1} \,.\, a}{r}$, from which r will be found $= \frac{\overline{m-p} \,.\, a}{mp}$.

Caſe 2.—n, m, p being given to find r. Since $\frac{m}{p} = \overline{1+r}|^{n}$, the log. $\overline{1+r}$ will be $= \frac{\log.\, m - \log.\, p}{n}$, hence $\overline{1+r}$, and conſequently r, will be known.

Caſe 3.—m, r, p being given to find n. This is derived from the preceding caſe, being $= \frac{\log.\, m - \log.\, p}{\log.\, 1+r}$.

Caſe 4.—a, m, p being given to find n ... $\overline{1+r}|^{n}$ being $= \frac{m}{p}$, $\overline{1+r}|^{n} - 1$ will be known; and ſince r is $= \frac{a \,.\, \overline{1+r}|^{n} - 1}{m}$, r will alſo be known, therefore, ſince log. $\overline{1+r}|^{n}$ is $= n \times$ log. $\overline{1+r}$, n will be known, being $= \frac{\log.\, \overline{1+r}|^{n}}{\log.\, 1+r}$.

Caſe 5.—a, r, p being given to find m. By *Caſe* 1, m may be eaſily found $= \frac{ap}{a - pr}$.

Caſe 6.—a, n, p being given to find m. The value of r may be derived from one of the foregoing theorems, in which a, p, n are given (being $= b \pm \sqrt{bb - 2bd}$), and hence $m = p \,.\, \overline{1+r}|^{n}$ will alſo be given.

Caſe 7.—n, r, p being given to find m. As r is given, this value is immediately obtained from the preceding caſe, being $= p \,.\, \overline{1+r}|^{n}$.

Caſe 8.—m, r, a being given to find p. By *Caſe* 1, r is $= \frac{\overline{m-p} \,.\, a}{mp}$, therefore $p = \frac{am}{a + mr}$.

Caſe 9.—n, m, r being given to find p. Since $\frac{m}{p} = \overline{1+r}|^{n}$ p will be $= \frac{m}{\overline{1+r}|^{n}}$.

Caſe 10.—n, m, a being given to find p. Let the value of r be found when m, n, a are given by one of the preceding theorems (being $= \sqrt{bb + 2bc} - b$), and $p = \frac{m}{\overline{1+r}|^{n}}$ will then be given.

Caſe 11.—n, m, p being given to find a. Since $\frac{m}{p} = \overline{1+r}|^{n}$, r will be $= \frac{m}{p}\Big|^{\frac{1}{n}} - 1$, and conſequently given; therefore the value of a may be found from the equation $m = \frac{\overline{1+r}|^{n} - 1}{r}$ to be $= \frac{mr}{\overline{1+r}|^{n} - 1}$.

Caſe 12.—m, p, r being given to find a. Let $\frac{m}{p}$ be ſubſtituted for its equal $\overline{1+r}|^{n}$ in the expreſſion $\frac{mr}{\overline{1+r}|^{n} - 1}$, and a will be $= \dfrac{mr}{\frac{m}{p} - 1} = \dfrac{mpr}{m-p}$.

Dr. Maſkelyne, in his introduction to Taylor's logarithms, has, with the view of facilitating theſe operations, had recourſe to the tables of logarithmic ſines and tangents, by putting $r = t^2 . \mathrm{A}$, $1 + r = \text{ſec.}^2\,\mathrm{A}$, $\overline{1+r}|^{n} = \text{ſec.}^2\,\mathrm{B}$, &c.; thus, in *Caſe* 1, the value of r becomes $= \frac{a}{m} \times t^2 . \mathrm{B}$; for $\frac{m}{p}$ being $= \overline{1+r}|^{n} = \text{ſec.}^2\,\mathrm{B}$, and $\dfrac{\frac{m}{p} - 1}{r} \times a = \dfrac{\text{ſec.}^2\,\mathrm{B} - 1}{r} \times a = \dfrac{t^2 . \mathrm{B}}{r} \times a$, $r \left(= \dfrac{m-p}{mp}\right)$ will be $= \dfrac{t^2 . \mathrm{B}}{m} \times a$. In like manner, in *Caſe* 12, $a = \dfrac{mr}{\overline{1+r}|^{n} - 1}$ becomes $= \dfrac{mr}{\text{ſec.}^2\,\mathrm{B} - 1} = \dfrac{mr}{t^2 . \mathrm{B}} = mr \times co - t^2 . \mathrm{B}$, or $m . t^2 . \mathrm{A} \times co - t^2 . \mathrm{B}$. But though the expreſſions appear more ſimple, I do not know that in general the operations will be found to be much facilitated by theſe means.

In the preceding caſes money has been ſuppoſed to be improved or diſcounted *yearly*. But all theſe different theorems may, however, be applied to the ſolution of caſes which require money to be improved or diſcounted at ſhorter intervals. Thus, ſuppoſing it were required to determine the amount of 50*l.*, when laid out *half yearly*, to accumulate at 4*l.* *per cent.* for the term of 30 years: p is $= 50$, $n = 2 \times 30 = 60$, r the intereſt of 1*l.* for half a year $= .02$, and $m = p . \overline{1+r}|^{n}$ becomes $= 50 \times \overline{1.02}|^{60} = 164.05$. If improved *quarterly* it will be $= 50 \times \overline{1.01}|^{4 \times 30} = 165$.

Again, if it were required to determine the amount of 5*l.* laid out *half yearly*, to be improved at 4*l.* *per cent.* during a term of 10 years. In this caſe $m = \dfrac{a \times \overline{1+r}|^{n} - 1}{r}$ will be $= \dfrac{5 \times \overline{1.02}|^{2 \times 10} - 1}{.02} = 121.486$, and if it be improved *quarterly*, it will be $= \dfrac{5 \times \overline{1.01}|^{4 \times 10} - 1}{.01} = 122.2$.

In like manner, if money be diſcounted at ſhorter intervals than a year, the preſent value will be obtained from the expreſſion $\dfrac{1}{\overline{1+r}|^{n}}$; thus, let the preſent value be required of 20*l.* payable at the end of 40 years, ſuppoſing money to be diſcounted every half year at 6*l.* *per cent.* Here n becomes $= 2 \times 40 = 80$, $r = \frac{.06}{2} = .03$, and conſequently $\pi = \dfrac{a}{\overline{1+r}|^{n}} = \dfrac{20}{\overline{1.03}|^{80}} = 1.8795$.

Let k be any fraction of a year in which money is to be improved or diſcounted, and the amount or preſent value may always be found from the amount or preſent value when money is improved or diſcounted yearly, being the ſame with ſuch amount or value at $\frac{r}{k}$ intereſt for kn years. Thus, the amount of 50*l.* improved *half yearly* at 4*l.* *per cent.* for 30 years is the ſame with the amount of 50*l.* improved *yearly* for 60 years at 2*l.* *per cent.*; the amount of 5*l.* *per ann.* improved half yearly for 10 years at 4*l.* *per cent.*, is the ſame with the amount of 5*l.* *per ann.* improved yearly for 20 years at 2*l.* *per cent.*; and 10*l.* diſcounted half yearly for 40 years at 6*l.* *per cent.* is the ſame with 10*l.* diſcounted yearly for 80 years at 3*l.* *per cent.* The different values of annuities, when payable yearly, half yearly, quarterly, or at ſhorter intervals, may in the ſame manner be deduced from the preceding theorems, but theſe are explained in the article ANNUITIES.

M. De Moivre, M. D'Alembert, and ſome others, inſtead of making the intereſt of 1*l.* for the kth part of a year $= \frac{r}{k}$, have choſen to make it $= \overline{1+r}|^{\frac{1}{k}} - 1$, and hence the amount of 1*l.* in n years, or its preſent value at the end of n years, will be the ſame, whether money be improved or diſcounted yearly, or at ſhorter intervals. But the amount of 1*l.* *per ann.* will be to its amount when improved yearly in the conſtant ratio of r to $k \times \overline{1+r}|^{\frac{1}{k}} - 1$, and the value of an annuity of 1*l.* will be to its value, when paid yearly, inverſely as r to $k . \overline{1+r}|^{\frac{1}{k}} - 1$, whatever the length of the term during which the money is to accumulate, or the annuity is to continue. Now, it is well known that the difference between the values of annuities payable yearly, and their values, when payable half-yearly, quarterly, or at ſhorter intervals, is always leſſened as the term is extend d, ſo that if the annuity be perpetual, the values will be the ſame, whether the payments are made yearly, or in any fractional part of the year; which can never be the caſe on the ſuppoſition above mentioned. When n is $= \log. \dfrac{r}{r - k . \overline{1+r}|^{\frac{1}{k}} - 1} \div \log. \overline{1+r}$, an annuity payable every kth part of the year, will be equal to the perpetuity, ſo that an annuity payable *half-yearly*, at 5*l.* *per cent.* for $90\frac{1}{2}$ years, or *quarterly* for 80 years, will be equal to the ſame annuity payable *yearly* for ever. And at 6*l.* *per cent.* the annuities will be of equal value if the term be only $72.\frac{1}{2}$ years in the one caſe, or $65.\frac{1}{5}$ years in the other. But while theſe rules, when the term is very long, give the values of *annuities* payable at ſhorter intervals than a year too high, they always, on the contrary, and eſpecially when the term is very long, give the *amount* of a ſum much too low. Thus ſuppoſing *one penny* to be laid out at 5*l.* *per cent.* compound intereſt at the birth of our Saviour, or 1810 years ago, it will accumulate, when money is improved *yearly*, to a ſum which is equal to 381,860,000 globes of ſolid gold, each equal to the earth in magnitude. When improved *half-yearly*, to a ſum which is equal to 1,121,470,000 of ſuch globes, and when improved *quarterly*, to a ſum which is equal to 1,945,680,000 ſuch globes; ſo that although in this long time the accumulation is nearly three times greater when money is improved *half-yearly*, and more than five times greater when improved *quarterly* than it is when money is improved *yearly*, yet according to the ſuppoſition that $\overline{1+r}|^{\frac{1}{k}}$ is the amount of 1*l.* in the kth part of a year, or $\overline{1+r}|^{\frac{kn}{k}} =$ its amount in n years, its accumulation will be the ſame, whether money is improved yearly, half-yearly, or quarterly. It may eaſily be ſhewn that $\overline{1+r}|^{\frac{1}{k}} - 1$ is always leſs than $\frac{r}{k}$, or, in other words, that this expreſſion does not give the full intereſt of 1*l.* for the kth part of a year. It is no wonder, therefore, that any theorems derived from a principle ſo erroneous, ſhould, like the preceding, lead to concluſions which are not only incorrect but abſurd

To the foregoing, a great number of other caſes might be added. But it will be ſufficient to give only a few of the moſt curious and important; ſome of which having occurred in practice, it would perhaps be improper to omit them.

Theorem 1.—To determine the time in which 1*l.* will be doubled by compound intereſt.

Solution.—Since $\overline{1 + r}|^{n}$ the amount of 1*l.* at the end of n years is in this caſe $= 2\ n$, or the required time, will be $= \frac{\log.\ 2}{\log.\ \overline{1 + r}}$; from which it appears that money doubles itſelf at 3*l. per cent.* in $23\frac{1}{2}$ years nearly; at 4*l. per cent.* in $17\frac{2}{3}$ years; at 5*l. per cent.* in $14\frac{1}{5}$ years; at 6*l. per cent.* in $11\frac{9}{10}$ years; at 8*l. per cent.* in 9 years; at 10*l. per cent.* in $7\frac{1}{4}$ years; and at 12*l. per cent.* in $6\frac{1}{6}$ years nearly.

Theorem 2.—Suppoſing money to be doubled by compound intereſt in n years, required r the rate of intereſt at which it has been improved.

Solution.—The log. $\overline{1 + r}$, by the preceding theorem being given $= \frac{\log.\ 2}{n}$, the value of r will alſo be given. Or, if the hyperbolic logarithm of 2 be expreſſed by h, it will be found $= 1 - \frac{\sqrt{n - 2\ h}}{\sqrt{n}}$.

Theorem 3.—Suppoſing 1*l.* to be doubled in n years at the intereſt r, and in m years at the intereſt $2\ r$, to find the ratio of m to n.

Solution.—Since $\overline{1 + r}|^{n}$ and $\overline{1 + 2\ r}|^{m}$ are each of them equal to 2, they will be equal to each other, and conſequently m will be to n as log. $\overline{1 + r}$ to log. $\overline{1 + 2\ r}$, or by fluxions and the binomial theorem, as $\frac{1}{2} + \frac{\overline{1 - r}\ .\ r}{4}$ to one very nearly, or ſtill more nearly, as $\frac{1}{2} + \frac{\overline{1 - r}\ .\ r}{4} + \frac{\overline{7 - 9\ r}\ .\ r^{3}}{24}$ to one.

Examples.—At 3 and 6 *per cent.* m and n are reſpectively to each other in the ratio of .50746 to one; at 4 and 8 *per cent.* of .50934 to one; at 5 and 10 *per cent.* of .51197 to one; at 6 and 12 *per cent.* of 51417 to one; at 8 and 16 *per cent.* of .51889 to one; at 10 and 20 *per cent.* of .52269 to one; and at 12 and 24 *per cent.* of .52681 to one. From theſe examples it appears that the higher the intereſt the greater will be the ratio of m to n. It follows alſo from the expreſſion $\frac{1}{2} + \frac{\overline{1 - r}\ .\ r}{4}$, &c. that money will not double itſelf at $2\ r$ intereſt in half the time that it doubles itſelf at r intereſt. The truth of this concluſion may perhaps be more ſatisfactorily proved in the following manner. Since $m : n = \log.\ \overline{1 + r} : \log.\ \overline{1 + 2\ r} = \log.\ \overline{1 + r} : \log.\ \overline{1 + r} + \log.\ \overline{1 + \frac{r}{r + 1}}$, we ſhall have $m : n = 1 : 1 + \frac{\log.\ \overline{1 + \frac{r}{\overline{1 + r}}}}{\log.\ \overline{1 + r}}$. But this latter fraction muſt be leſs than unity, therefore m will always be to n in a greater ratio than as 1 to 2.

Theorem 4.—To determine the ſum to which an annuity a will accumulate at the end of n years, ſuppoſing ſuch annuity to be received annually, and its intereſt to be improved *half-yearly*.

Solution.—The ſeries expreſſing theſe accumulations is

$$a \left(\overline{1 + \frac{r}{2}}|^{2} + \overline{1 + \frac{r}{2}}|^{4} + \overline{1 + \frac{r}{2}}|^{6} \ldots\ldots + \overline{1 + \frac{r}{2}}|^{2\,n-2} \right) = a \times \frac{\overline{1 + \frac{r}{2}}|^{2\,n} - 1}{\overline{1 + \frac{r}{2}}|^{2} - 1}.$$

Example.—Let $a = 500$, $n = 30$, and $r = .05$, the foregoing expreſſion will then be $\frac{\overline{1.025}|^{60} - 1}{\overline{1.025}|^{2} - 1} \times 500 = 67.1567 \times 500 = 33{,}578.35$. If the above annuity and its intereſt be improved yearly, the accumulation will be equal to 33,219.4*l.* and if both principal and intereſt be improved half-yearly, they will amount to 33,998*l.*

Theorem 5.—To determine the ſum p which at compound intereſt will amount in the time n to N, and in the time m to M.

Solution.—In this caſe $p\ .\ \overline{1 + r}|^{n} = \text{N}$, and $p\ .\ \overline{1 + r}|_{m} = \text{M}$, from which two equations, the log. of p may be found $= \frac{m\ .\ \log.\ \text{N} - n\ .\ \log.\ \text{M}}{m - n}$.

Corollary 1.—If the ſum p amounts to N in the time n, the log. of the amount M in the time m will be $= \frac{m\ .\ \log.\ \text{N} - \overline{m - n}\ .\ \log.\ p}{n}$.

Corollary 2.—If the ſum p in n years amounts to N, the time m in which it will amount to M, will be $= \frac{n\ .\ \overline{\log.\ \text{N} - \log.\ p}}{\log.\ \text{M} - \log.\ p}$.

Theorem 6.—Suppoſing the ſum a to become payable annually for n years, at what time t might all the payments ($n\ a$) be made at once, ſo as to be an equivalent to the ſeveral annual payments.

Solution.—The preſent value of the annuity a for n years (ſee ANNUITIES) being $= \frac{a}{r} - \frac{a}{r\ .\ \overline{1 + r}|^{n}}$, will in this caſe be $= \frac{n\ a}{\overline{1 + r}|^{t}}$, from which equation t may be found

$$= \frac{\log.\ n\ r + \log.\ \overline{1 + r}|^{n} - \log.\ \overline{\overline{1 + r}|^{n} - 1}}{\log.\ \overline{1 + r}}.$$

Example.—Let $a = 10$, $n = 15$, and $r = .05$, or, in other words, let an annuity of 10*l.* be payable annually for 15 years at 5*l. per cent.* at what period will the ſingle payment of 150*l.* be an equivalent to this annuity? In this caſe t will be $=$

$$\frac{\log.\ .5 + \log.\ \overline{1.05}|^{15} - \log.\ \overline{\overline{1.05}|^{15} - 1}}{\log.\ 1\ .\ 05} = 7.5$$

nearly, or $7\frac{1}{2}$ years. By the ſame rule, if the annuity were for 30 or 50 years, a ſingle payment made at the end of 13.7 years, or at the end of $20.\frac{1}{2}$ years, will be an equivalent to ſuch annuities reſpectively.

Corollary.—If the payments, inſtead of always being a, vary each year, ſo that in the firſt, ſecond, and third years they are a, b, c, d, &c. reſpectively, and the whole amount of them be p, the time t will be =

$$\frac{\log.\ p - \log.\left(\frac{a}{1+r} + \frac{b}{\overline{1+r}|^{2}} + \frac{c}{\overline{1+r}|^{3}} + \&c.\right)}{\log.\ \overline{1+r}}$$

Theorem 7.—Suppoſing the ſum b to be now borrowed on condition that the annuity c ſhould be paid in diſcharge of it, after the expiration of n years; for how many years t ſhould ſuch annuity be continued from that time ſo as to be an equivalent to the ſum ſo advanced?

Solution.—The amount of b in n years being $b\ .\ \overline{1+r}|^{n}$, and the value of the annuity c for t years being $\frac{c\ .\ \overline{1+r}|^{t} - c}{r\ \overline{1+r}|^{t}}$, theſe two expreſſions, by the condition of the problem, will be equal to each other. Let $\frac{c}{c - b\,r\ .\ \overline{1+r}|^{n}}$ be denoted by d, then may t be eaſily found $= \frac{\log.\ d}{\log.\ \overline{1+r}}$. Thus, if $b = 1032 \ldots\ldots c = 400 \ldots n = 37 \ldots$ and $r = .05$, d will be $= \frac{400}{400 - .05 \times 1032 \times 6.081} = 46.4$, and $t = \frac{\log.\ \text{of}\ 46.4}{\log.\ \text{of}\ 1.05} = 31.4$, that is, if 1032*l.* be now borrowed on condition that the debt ſhould be diſcharged at the end of 37 years by an annual payment of 400*l.* ſuch payment, computing at 5*l.* *per cent.* ſhould be continued for $31\frac{2}{5}$ years.

Corollary.—If c be $= \overline{1+r}|^{n} \times b\,r$, the annual payment muſt be continued for ever; if c be leſs than $b\,r \times \overline{1+r}|^{n}$, the debt can never be repaid.

From any four of the above quantities being given the fifth may be obtained without much difficulty. But it cannot be neceſſary to purſue this ſubject further, as the ſolution of theſe or any other caſes in compound intereſt may be eaſily derived from the principles already explained in this article.

See on this ſubject, Jones's Synopſis Palmariorum Matheſeos, part. i. ſect. 3. chap. 10. Gardiner's Tables of Logarithms, p. 13. 3d edition. Philoſ. Tranſactions, vol. lx. p. 508. and vol. lxvi. p. 109. Taylor's Tables of Logarithms, p. 30; and Mazere's Scriptores Logarithmici, vol. v. p. 220. See alſo ANNUITIES *Certain*, and DISCOUNT.

A mercantile friend has favoured the editor with the following *univerſal* rule for finding the intereſt upon *any* ſum at *any* rate, for *any* number of days.

Multiply the *ſum* by the *rate* of intereſt, and multiply that product by the *number* of days; then divide that product by 36500. The quotient will be the anſwer.

Now ſuppoſe the queſtion to be, What is the intereſt upon 127*l.* at 3*l.* *per cent. per annum* for 254 days?

```

```

It is evident, that in multiplying 127 by 3, according to the *firſt* operation of the rule, the amount is *increaſed* one hundred times too much, for the product 381 is only three, and eighty-one hundredths, or 381*l.* which is equal to 3*l.* 16*s.* 2¼*d.* or the intereſt of 127*l.* at 3 *per cent.* for one year. Therefore, to correct this *firſt* error, the product 381 muſt be divided by 100, and it will be right.

But in following the rule, the *firſt* error is *continued*, and we go on to multiply that product by the number of days, by which it is alſo evident that the product 96774 includes a *ſecond* error of 365 times too much, being for *days* inſtead of for *years*, and the amount of the *two* errors taken together is 100 times 365 times too much, or 36,500 times too much, therefore, to bring it right, it muſt be divided by that number.

This explains the principle of the firſt univerſal rule, which requires *three* operations, *becauſe* it is adapted to *any* rate of intereſt whatever.

To find the intereſt upon any ſum at 5 *per cent.* for any number of days:

Rule.—Multiply the ſum by the number of days, and divide the product by 7300.

Example.

What is the intereſt upon 2745*l.* for 365 days?

```
          365

```

Intereſt at 5 *per cent.* being the moſt common rate in Great Britain, may in general be worked as ſpeedily by the above ſhort rule as it can be found by referring to the tables in common uſe.

The editor's correſpondent has never yet met with ſo ſhort a rule as this, and as 5 *per cent.* is the general and legal rate of intereſt in this country, it muſt be very uſeful to mercantile perſons.

The explanation of the principle of the firſt rule being underſtood as above, there can be no difficulty in the laſt rule, it being derived from it.

When the intereſt is at any other rate, take the following rule:

Multiply the ſum by the number of days; multiply that product by the rate of intereſt, then divide by 36500.

Example.

What is the intereſt upon 1612*l.* for 154 days at 4 *per cent.*?

```
            154
         -------
           6448

```

If the rate of intereſt is not in even pounds, ſuch as 2½, 3½, or 4½ *per cent.* take the following rule:

Multiply the ſum by the number of days; multiply the product by double the rate of intereſt, then divide by 73000.

Example:—What is the intereſt upon 2746*l.* for 328 days at 3½ *per cent.*?

```
           2746
            328

```

Any calculation made by the ſecond rule may be proved by the third rule, and *vice verſâ*. Therefore every calculation of intereſt at any rate whatever, may be made by either of thoſe rules. When an intereſt account of conſiderable length is required to be made out, it may be done as much ſooner by this method than it can be done by any intereſt tables whatever, as there are different lines to be caſt.

By the following table of rules, intereſt upon any ſum for any number of days at the ſeveral rates of ¼, ½, 1, 1¼, 2, 2½, 4, 5, and 10 *per cent. per annum*, may be caſt by two operations only, namely, one multiplication and one diviſion.

Firſt, multiply the ſum by the number of days, then divide the product by the number ſtanding againſt the rate of intereſt, and the quotient will be the anſwer.

For intereſt at			divide by
¼ *per cent.*			146000
½	-	-	73000
1	-	-	36500
1¼	-	-	29200
2	-	-	18250
2½	-	-	14600
4	-	-	9125
5	-	-	7300
10	-	-	3650

The above rule may be ſtill further ſhortened in practice, by cutting off one figure each from the dividend and the diviſor, and in that caſe it will not in any inſtance make more than one farthing difference.

Intereſt is the compenſation which the borrower pays to the lender, for the profit which he has an opportunity of making by the uſe of the money. Part of that profit naturally belongs to the borrower, who runs the riſk and takes the trouble of employing it; and part to the lender, who affords him the opportunity of making this profit. Intereſt has been ſometimes confounded with uſury; and the latter term, the ſound of which is odious, has been occaſionally miſapplied and eſtimated on erroneous principles. (See Usury.) Accordingly thoſe who are enemies to intereſt in general, making no diſtinction between that and the kind of uſury which is criminal, hold any increaſe of money to be indefenſibly uſurious. This they ground, as well on the prohibition of it by the law of Moſes among the Jews, as alſo upon what is ſaid to be laid down by Ariſtotle in a paſſage, (Polit. l. i. c. 10.) ſuſpected to be ſpurious, that money is naturally barren, and that to make it breed money is prepoſterous, and a perverſion of the end of its inſtitution, which was only to ſerve the purpoſes of exchange, and not of increaſe. Hence the ſchool divines have branded the practice of taking intereſt as contrary to the divine law, both natural and revealed; and the canon law (Decret. l. v. tit. 19,) has proſcribed the taking of any, the leaſt, increaſe for the loan of money as a mortal ſin. But it has been obſerved in reply, that the Moſaical precept was clearly a political, and not a moral precept. It only prohibited the Jews from taking uſury of their brethren; but, in expreſs words, (Deut. xxiii. 20.) permitted them to take it of a ſtranger, which proves that the taking of moderate uſury, as a reward for the uſe, for ſo the word ſignifies, is not *malum in ſe;* ſince it was allowed where any but an Iſraelite was concerned. As to the reaſon, deduced from the natural barrenneſs of money, and aſcribed to Ariſtotle, the ſame may with equal force be alleged of houſes, which never breed houſes; and of twenty other things, which nobody doubts it is lawful to make profit of, by letting them to hire. And though money was originally uſed for the purpoſes of exchange, yet the laws of any ſtate may be well juſtified in permitting it to be turned to the purpoſes of profit, if the convenience of ſociety (the great end for which money was invented) ſhall require it. That the allowance of moderate intereſt tends greatly to the benefit of the public, eſpecially in a trading country, will appear from that generally acknowledged principle, that commerce cannot ſubſiſt without mutual and extenſive credit. Unleſs money can be borrowed, trade cannot be carried on; and if no premiums were allowed for the hire of money, few perſons would care to lend it; or at leaſt the eaſe of borrowing at a ſhort warning (which is the life of commerce) would be entirely at an end. Thus, in the dark ages of monkiſh ſuperſtition and civil tyranny, when intereſt was laid under a total interdict, commerce was alſo at its loweſt ebb, and fell entirely into the hands of the Jews and Lombards: but when men's minds came to be more enlarged, when true religion and real liberty revived, commerce grew again into credit; and again introduced with itſelf its inſeparable companion, the doctrine of loans upon intereſt. And, as to any ſcruples of conſcience, ſince all other conveniences may either be bought or hired, but money only can be hired, there ſeems to be no greater oppreſſion in taking a recompence or price for the hire of this than of any other convenience. To demand an exorbitant price is equally contrary to conſcience, for the loan of a horſe, or the loan of a ſum of money; but a reaſonable equivalent for the temporary inconvenience, which the owner may feel by the want of it, and for the hazard of his loſing it entirely, is not more immoral in one caſe than it is in the other. Indeed, the abſolute prohibition of lending upon any, even moderate intereſt, introduces the very inconvenience which it ſeems meant to remedy. The neceſſity of individuals will make borrowing unavoidable. Without ſome profit allowed by law, there will be but few lenders: and thoſe principally bad men, who will break through the law, and take a profit; and then will endeavour to indemnify themſelves from the danger of the penalty, by making that profit exorbitant. Accordingly it is well obſerved by Grotius, (De Jur. Bell. et Pac. l. ii. c. 12. § 22.) "if the compenſation allowed by law does not exceed the proportion of the hazard run, or the want felt, by the loan, its allowance is repugnant neither to the revealed nor the natural law: but if it exceeds thoſe bounds, it is then oppreſſive uſury: and though the municipal laws may give it impunity, they never can make it juſt." The exorbitance or moderation of intereſt depends upon two circumſtances, the inconvenience of parting with it for the preſent, and the hazard of loſing it entirely. The rate of intereſt will be generally in a compound ratio, formed out of the inconvenience and the hazard.

Mr. Locke, Mr. Law, and Mr. Monteſquieu, as well as many other writers, ſeem to have imagined that the increaſe of the quantity of gold and ſilver, in conſequence of the diſcovery of the Spaniſh Weſt Indies, was the real cauſe of the lowering the rate of intereſt through the greater part of Europe. Thoſe metals, they ſay, having become of leſs value than ſilver, the uſe of any particular portion of them became neceſſarily of leſs value too, and conſequently the price which could be paid for it. This notion appears at firſt ſight very plauſible; but it has been conteſted, not to ſay refuted, by Mr. Hume and Dr. Smith. It is in vain, ſays the firſt of theſe writers, (Eſſays, vol. i. eſſ. iv.) to look for the cauſe of the fall or riſe of intereſt in the greater or leſs quantity of gold and ſilver, which is fixed in any nation. High intereſt ariſes from *three* circumſtances: A great demand for borrowing; little riches to ſupply that demand; and great profits ariſing from commerce: and theſe circumſtances are a clear proof of the ſmall advance of commerce and induſtry, not of the ſcarcity of gold and ſilver. Low intereſt, on the other hand, proceeds from the three oppoſite circumſtances: a ſmall demand for borrowing; great riches to ſupply that demand; and ſmall profits ariſing from commerce: and theſe circumſtances are all connected together, and proceed from the increaſe of induſtry and commerce, not of gold and ſilver. In inveſtigating the cauſes and effects of a great or ſmall demand for borrowing, Mr. Hume traces the origin and eſtabliſhment of the *landed* intereſt; and he obſerves, after tracing the manner in which ſome perſons become proprietors of land, and the influence of a ſettled revenue on thoſe who are entirely without occupation, that the prodigals among the landholders will always be more numerous than the miſers. In a ſtate, therefore, where there is nothing but a landed intereſt, as there is little frugality, the borrowers muſt be very numerous, and the rate of intereſt muſt bear proportion to it; the difference depends not on the quantity of money, but on the habits and manners which prevail. By this alone the demand for borrowing is increaſed or diminiſhed. Were money ſo plentiful as to make an egg be ſold for ſixpence; ſo long as there are only landed gentry and peaſants in the ſtate, the borrowers muſt be numerous, and intereſt high. The rent for the ſame farm would be heavier and more bulky; but the ſame idleneſs of the landlord, with the higher price of commodities, would diſſipate it in the ſame time, and produce the ſame neceſſity and demand for borrowing. The ſecond circumſtance, above-mentioned, *viz.* the great or little riches to ſupply the demand, depends alſo on the habits and way of living of the people, not on the quantity of gold and ſilver. In order to have, in any ſtate, a greater number of lenders, it is not ſufficient nor requiſite that there be great abundance of the precious metals. It is only requiſite that the property, or command of that quantity, which is in the ſtate, whether great or ſmall, ſhould be collected in particular hands, ſo as to form conſiderable ſums, or compoſe a great *monied* intereſt; this begets a number of lenders, and ſinks the rate of uſury: and this, Mr. Hume affirms, depends not on the quantity of ſpecie, but on particular manners and cuſtoms, which make the ſpecie gather into ſeparate ſums or maſſes of conſiderable value. The reduction of intereſt muſt proceed from an increaſe of induſtry and frugality, of arts and commerce. Beſides the peaſants and the proprietors of land, there muſt be another rank of men, who, receiving from the former the rude materials, work them into their proper form, and retain part for their own uſe and ſubſiſtence. As induſtry increaſes, and the views of men enlarge, it is found that the moſt remote parts of the ſtate can aſſiſt each other as well as the more contiguous, and that this intercourſe of good offices may be carried on to the greateſt extent and intricacy. Hence the origin of " Merchants," who ſerve as agents between different parts of the ſtate ; and in all the tranſactions which this buſineſs of connecting agency or merchandize occaſions, it is neceſſary and reaſonable that a conſiderable part of the commodities and labour ſhould belong to the merchant, to whom, in a great meaſure, they are owing. Theſe commodities he will ſometimes preſerve in kind, or more commonly convert into money, which is their common repreſentation. If gold and ſilver have increaſed in the ſtate, together with the induſtry, it will require a great quantity of theſe metals to repreſent a great quantity of commodities and labour. If induſtry alone has increaſed, the prices of every thing muſt ſink, and a ſmall quantity of ſpecie will ſerve as a repreſentative. Trade, ſays Mr. Hume, increaſes frugality, and among merchants there is the ſame overplus of miſers above prodigals, as, among the poſſeſſors of land, there is the contrary. Commerce increaſes induſtry, as well as frugality. Merchants beget induſtry, and by their frugality they acquire great power over that induſtry, and collect a large property in the labour and commodities which they are the chief inſtruments in producing. Without commerce the ſtate muſt conſiſt chiefly of landed gentry, whoſe prodigality and expence make a continual demand for borrowing ; and of peaſants, who have no ſums to ſupply that demand. The money never gathers into large ſtocks or ſums, which can be lent at intereſt. Commerce alone aſſembles it into conſiderable ſums ; and this effect it has merely from the induſtry which it begets, and the frugality which it inſpires, independent of that particular quantity of precious metal which may circulate in the ſtate. Thus an increaſe of commerce neceſſarily raiſes a great number of lenders, and by that means produces lowneſs of intereſt. The next conſideration is, that this increaſe of commerce diminiſhes the profits ariſing from that profeſſion, and gives riſe to the *third* circumſtance, above-mentioned, requiſite to produce lowneſs of intereſt. When commerce has become extenſive, and employs large ſtocks, there muſt ariſe rivalſhips among the merchants, which diminiſh the profits of trade, at the ſame time that they increaſe the trade itſelf. The low profits of merchandize induce the merchants to accept more willingly of a low intereſt, when they leave off buſineſs, and begin to indulge themſelves in eaſe and indolence. Low intereſt and low profits both ariſe from an extenſive commerce, and mutually forward each other. No man will accept of low profits, where he can have high intereſt ; and no man will accept of low intereſt, where he can have high profits. An extenſive commerce, by producing large ſtocks, diminiſhes both intereſt and profits ; and is always aſſiſted, in its diminution of the one, by the proportional ſinking of the other. Thoſe, ſays our author, who have aſſerted, that the plenty of money was the cauſe of low intereſt, ſeem to have taken a collateral effect for a cauſe ; ſince the ſame induſtry, which ſinks the intereſt, commonly acquires great abundance of the precious metals. But though plenty of money and low intereſt naturally ariſe from commerce and induſtry, they are altogether independent of each other. As to the reduction of intereſt, which has taken place in England, France, and other kingdoms of Europe, that have no mines, it has been gradual ; and has not proceeded, ſays Mr. Hume, from the increaſe of money, conſidered merely in itſelf ; but from that of induſtry, which is the natural effect of the former increaſe, in that interval, before it raiſes the price of labour and proviſions. Dr. Smith (Wealth of Nations, vol. ii. p. 39.) coincides in inion with Mr. Hume, and propoſes a very ſhort and plain gument, which, he thinks, may ſerve to explain the fallacy which thoſe have been miſled who aſcribe the lowering of the rate of intereſt to the increaſe of the quantity of gold and ſilver. Before the diſcovery of the Spaniſh Weſt Indies, 10 *per cent.* ſeems to have been the common rate of intereſt through the greater part of Europe. It has ſince that time in different countries ſunk to 6, 5, 4, and 3 *per cent.* Let us ſuppoſe that in every particular country the value of ſilver has ſunk preciſely in the ſame proportion as the rate of intereſt ; and that in thoſe countries, for example, where intereſt has been reduced from 10 to 5 *per cent.*, the ſame quantity of ſilver can now purchaſe juſt half the quantity of goods which it could have purchaſed before. This ſuppoſition will not, as Dr. Smith believes, be found any where agreeable to the truth, but it is the moſt favourable to the opinion now examined ; and even upon this ſuppoſition it is utterly impoſſible that the lowering of the value of ſilver could have the ſmalleſt tendency to lower the rate of intereſt. If 100*l.* are in theſe countries now of no more value than 50*l.* were then, 10*l.* muſt now be of no more value than 5*l.* were then. Whatever were the cauſes which lowered the value of the capital, the ſame muſt neceſſarily have lowered that of the intereſt, and exactly in the ſame proportion. The proportion between the value of the capital and that of the intereſt muſt have remained the ſame, though the rate had never been altered. By altering the rate, on the contrary, the proportion between theſe two values is neceſſarily altered. If 100*l.* now are worth no more than 50*l.* were then, 5*l.* now can be worth no more than 2*l.* 10*s.* were then. By reducing the rate of intereſt, therefore, from 10 to 5 *per cent.*, we give for the uſe of a capital, which is ſuppoſed to be equal to one-half of its former value, an intereſt which is equal to one-fourth only of the value of the former intereſt. Any increaſe in the quantity of ſilver, while that of the commodities circulated by means of it remained the ſame, could have no other effect than to diminiſh the value of that metal. The nominal value of all ſorts of goods would be greater, but their real value would be preciſely the ſame as before. They would be exchanged for a greater number of pieces of ſilver, but the quantity of labour which they could command, the number of people whom they could maintain and employ, would be preciſely the ſame. The capital of the country would be the ſame, though a great number of pieces might be requiſite for conveying any equal portion of it from one hand to another. The funds for maintaining productive labour being the ſame, the demand for it would be the ſame. Its price, or wages, therefore, though nominally greater, would really be the ſame, they would be paid in a greater number of pieces of ſilver ; but they would purchaſe only the ſame quantity of goods. The profits of ſtock would be the ſame both nominally and really. The profits of ſtock are not computed by the number of pieces of ſilver with which they are paid, but by the proportion which thoſe pieces bear to the whole capital employed. The common proportion between capital and profit would be the ſame, and conſequently the common intereſt of money ; what can commonly be given for the uſe of money being neceſſarily regulated by what can commonly be made of it. The intereſt of money, keeping pace always with the profits of ſtock, might be greatly diminiſhed, though the value of money, or the quantity of goods which any particular ſum could purchaſe, was greatly augmented.

In countries, ſays our ingenious author, where intereſt is permitted, the law, in order to prevent the extenſion of uſury, generally fixes the higheſt rate which can be taken without incurring a penalty. This rate ought always to be ſomewhat above the loweſt market price, or the price which is commonly paid for the uſe of money by thoſe who can give the moſt undoubted ſecurity. If this legal rate ſhould be fixed below the loweſt market rate, the effects of this fixation muſt be nearly the ſame as thoſe of a total prohibition of intereſt. The creditor will not lend his money for leſs than the uſe of it is worth, and the debtor muſt pay him for the riſk which he runs by accepting the full value of that uſe. The legal rate, though it ought to be ſomewhat above, ought not to be much above the loweſt market rate. If the legal rate of intereſt in Great Britain, for example, was fixed ſo high as 8 or 10 *per cent.*, the greater part of the money which was to be lent, would be lent to prodigals and projectors, who alone would be willing to give this high intereſt. Where the legal rate of intereſt is fixed but a very little above the loweſt market rate, ſober people are univerſally preferred, as borrowers, to prodigals and projectors. Then a great part of the capital of the country is thrown into the hands in which it is moſt likely to be employed with advantage. The ordinary market price of land depends every where upon the ordinary market rate of intereſt. If the rent of land ſhould fall ſhort of the intereſt of money by a conſiderable difference, nobody would buy land, which would ſoon reduce its ordinary price. On the contrary, if the advantages ſhould much more than compenſate the difference, every body would buy land, which would ſoon again raiſe its ordinary price. When intereſt was at 10 *per cent.*, land was commonly ſold for 10 and 12 years' purchaſe. As intereſt ſunk to 6, 5, and 4 *per cent.*, the price of land roſe to 20, 25, and 30 years' purchaſe. As to the legal intereſt in this country, it has varied and decreaſed for 200 years paſt according to the acceſſion of trade, the introduction of paper credit, and other circumſtances. The ſtat. 37 Hen. VIII. c. 9. confined intereſt to 10 *per cent.* In the reign of Edward VI. religious zeal prohibited all intereſt. The ſtatute of Henry VIII. was revived by the 13th of Elizabeth, cap. 8. and 10 *per cent.* continued the legal rate of intereſt till the 21ſt of James I., when it was reſtricted to 8 *per cent.* It was reduced to 6 *per cent.* ſoon after the reſtoration, and by the 12th of Ann. ſtat. 2. cap. 16. it was brought down to 5 *per cent.* yearly, which is now the greateſt legal intereſt that can be taken. But yet, if a contract which carries intereſt be made in a foreign country, our courts will direct the payment of intereſt according to the law of that country, in which the contract was made.

INTEREST, *Intereſſe*, in *Law*, is commonly taken for a chattel real, as a leaſe for years, &c. and more particularly for a future term; in which ſenſe it is ſaid in pleading, that one is poſſeſſed *de intereſſe termini*: therefore an eſtate in lands is better than a right or intereſt in them. But in legal underſtanding, an intereſt extends to eſtates, rights, and titles, that a man hath in or out of lands, &c. ſo as by grant of his whole intereſt in ſuch lands, a reverſion therein, as well as poſſeſſion, in fee-ſimple, ſhall paſs.

INTEREST *on legacies*. In caſe of a veſted legacy, due immediately, and charged on land or money in the funds, which yield an immediate profit, intereſt ſhall be payable thereon from the teſtator's death; but if charged only on the perſonal eſtate, which cannot be immediately got in, it ſhall carry intereſt only from the end of the year, after the death of the teſtator. If a legacy be deviſed, and no certain time of payment mentioned, and the legatee be an infant, he ſhall have intereſt for the legacy from the expiration of one year after the teſtator's death; but if the legatee be of full age, he ſhall have no intereſt but from the time of the demand of the legacy. Where a legacy is payable at a day certain, it muſt be paid with intereſt from that day.

INTEREST, *Punitory*. See PUNITORY.

INTEREST or *no Intereſt*, a denomination applied to inſurances made without having any property on board the ſhips, in which large ſums were inſured. The ſtatute 19 Geo. II. c. 37. enacted that all ſuch inſurances ſhould be null and void. See *Marine* INSURANCE.

INTERESTED WITNESS. See WITNESS.

INTERESTING, in the Suppl. to the folio Encyclopédie, has been made an article for the Beaux Arts, without the leaſt alluſion to muſic. But dull and unintereſting muſic is, perhaps, more tireſome than the ſame degree of inſipidity in painting and poetry. You can quit a picture or a book whenever you pleaſe; but at a public performance of muſic, you have no eſcape from the bad compoſition or performance. A young compoſer, ambitious of fame, and of endearing himſelf to the public, ſhould never write for writing ſake, he ſhould not ſeize his pen without ideas, without a ſubject. There is no art which has more alluring means of obtaining attention. Grace, pathos, fire, fancy, hilarity, rich harmony, and learned modulation, cannot all have admiſſion in the ſame piece; yet it is abſolutely neceſſary that at leaſt ſome one of theſe excellencies ſhould predominate throughout a regular movement. And where a compoſer, not certain of his fertility and powers of pleaſing, has haſtily committed his thoughts to paper, he ſhould ſhut it up in his deſk for at leaſt nine days, if not nine years; at the end of which he ſhould perform it as the production of a ſtranger; then aſk himſelf what *intereſt* he thinks his piece would excite in an intelligent and impartial audience; and if ſelf-love is not the blindeſt of all loves, he will perceive where he is dull, and where genius and abilities are wanting.

INTERFEMINEUM, a word uſed by ſome to expreſs the perinæum.

INTERFERE, in the *Manege*. A horſe interferes, when the ſides of one of his ſhoes ſtrikes againſt and hurts one of the fetlocks. See CUTTING.

INTERJECTION, in *Grammar*, an expreſſion uſed to denote ſome ſudden motion or paſſion of the mind; as *oh! oh!* Theſe exclamations, uttered in a ſtrong and paſſionate manner, are conſidered by ſome writers as the firſt elements or beginnings of ſpeech.

As the greateſt part of the expreſſions uſed on theſe occaſions are taken from nature alone, the real interjections in moſt languages are monoſyllables: and as all nations agree in thoſe natural paſſions, ſo do they agree in the ſigns and indications of them; as of love, mirth, &c.

Some deny the interjections to be words, or any part of ſpeech; and make them mere natural ſigns of the motions or paſſions of the mind, expreſſed by theſe inarticulate ſounds, ſeveral whereof brutes have in common with us: but as theſe are paſſions, and muſt be repreſented in diſcourſe, the interjection has a good foundation in nature, and is a neceſſary part of ſpeech.

Mr. Harris obſerves, that interjections coincide with no part of ſpeech, but are either uttered alone, or elſe thrown into a ſentence, without altering its form, either in ſyntax or ſignification; and that they are not ſo properly parts of ſpeech, as adventitious ſounds; certain voices of nature, rather than voices of art, expreſſing thoſe paſſions and natural emotions, which ſpontaneouſly ariſe in the human ſoul, upon the view or narration of intereſting events. Hermes, p. 285.

Mr. H. Tooke, in his "Diverſions of Purley," excludes interjections from the parts of ſpeech; and aſſerts, that "the dominion of ſpeech is erected upon the downfall of interjections." See GRAMMAR.

The Greeks confound their interjections with adverbs, and the Hebrews confound them with their adverbs and prepoſitions: calling them all by the general name particle.

INTERIM, a term borrowed from the Latin, ſignifying *in the mean time.* It was firſt brought into popular uſe by Charles V. in 1548, in order to compoſe the diſturbances of Germany.

The interim of that prince was a kind of ordinance, or regulation, to be obſerved in the empire with regard to the articles of religion then controverted, till ſuch time as they ſhould be determined by a council; and therefore was called interim.

When it was laid before the diet, the archbiſhop of Mentz, preſident of the electoral college, thanked the emperor for his unwearied endeavours to reſtore peace to the church, and in the name of the diet, ſignified their approbation of the ſyſtem of doctrine which he had prepared, together with their reſolution of conforming to it in every particular. Although the whole diet was amazed at a declaration ſo unprecedented and unconſtitutional, as well as at the preſumption of the archbiſhop, in pretending to deliver the ſenſe of the diet, on a point which had not been the ſubject of conſultation or debate; none had the courage to contradict what he had ſaid. The emperor held the archbiſhop's declaration to be a full conſtitutional ratification of the interim, and prepared to enforce the obſervance of it, as a decree of the empire.

It was ſaid to have been drawn up by two Catholics and a Proteſtant; but as it retained moſt of the doctrines and ceremonies of the Romaniſts, though expreſſed for the moſt part in the ſofteſt words, or in ſcriptural phraſes, or in terms of ſtudied ambiguity, excepting that of marriage, which was allowed to prieſts, and communion, which was adminiſtered to the laity under both kinds, moſt of the Proteſtants rejected it. Thoſe who admitted it were nick-named Interimiſts, or Adiaphoriſts. Indeed the interim equally diſguſted the generality of both parties, the Proteſtants and Catholics.

Beſides this, there were two other interims made: the one called the interim of Leipſic, the other by the divines of Franconia, who, refuſing to accept the two former, made another for themſelves.

INTERIOR. See Internal.

Interior *Figure, Angle of.* See Angle.

Interior *Polygon.* See Polygon.

Interior *Talus.* See Talus.

INTERLACKEN, in *Geography*, a town of Switzerland, and capital of a conſiderable bailiwick, in the canton of Berne: deriving its name from an abbey, ſituated between the lakes of Brientz and Thun, and ſecularized in the year 1528; 32 miles S.E. of Berne.

INTERLINEATION, ſomething inſerted between two lines. See Deed.

INTERLOCUTORY Decree. In a ſuit in equity, if any matter of fact be ſtrongly controverted, the fact is uſually directed to be tried at the bar of the court of king's bench, or at the aſſizes upon a feigned iſſue. If a queſtion of mere law ariſes in the courſe of a cauſe, it is the practice of the court of chancery to refer it to the opinion of the judges of the court of king's bench, upon a caſe ſtated for that purpoſe.

In ſuch caſes interlocutory decrees or orders are made. See Decrees.

Interlocutory *Judgments* are ſuch as are given in the middle of a cauſe, upon ſome plea, proceeding on default, which is only intermediate, and does not finally determine or complete the ſuit. But the interlocutory judgments moſt uſually ſpoken of, are thoſe incomplete judgments, whereby the right of the plaintiff is eſtabliſhed, but the *quantum* of damages ſuſtained by him is not aſcertained, which is the province of a jury. In ſuch a caſe, a writ of inquiry iſſues to the ſheriff, who ſummons a jury, enquires of the damages, and returns to the court the inquiſition ſo taken, whereupon the plaintiff's attorney taxes coſts, and ſigns final judgment. See Judgment.

Interlocutory *Order,* that which decides not the cauſe, but only ſettles ſome intervening matter relating to the cauſe.

As, where an order is made in chancery for the plaintiff to have an injunction to quit poſſeſſion till the hearing of the cauſe; this order, not being final, is called interlocutory.

INTERLOPERS are properly thoſe, who, without due authority, hinder the trade of a company, or corporation lawfully eſtabliſhed, by dealing in the ſame way.

INTERLOPING, the intercepting or diſturbing the traffic of a company; or the taking up a new trade, or the employment, to the prejudice of thoſe who were brought up in it.

INTERLUCATION, in *Huſbandry*, the thinning of a wood, or letting in light between, by lopping or cutting away boughs.

INTERLUDE, an entertainment exhibited on the theatre between the acts of a play, to amuſe the ſpectators while the actors take breath, and ſhift their dreſs; or to give time for changing the ſcenes and decorations.

In the ancient tragedy, the chorus ſung the interludes, to ſhew the intervals between the acts.

Interludes, among us, uſually conſiſt of ſongs, dances, feats of activity, concerts of muſic, &c.

Ariſtotle and Horace give it for a rule, that the interludes ſhould conſiſt of ſongs built on the principal parts of the drama; but ſince the chorus has been laid down, dancers, buffoons, &c. ordinarily furniſh the interludes.

INTERMEDIATE, is uſually underſtood of the ſpace of time elapſed from any certain point to any other.

In *Chemiſtry*, thoſe ſubſtances are called intermediate, by means of which, other ſubſtances, incapable of uniting together of themſelves, may be united.

INTERMEWING, in *Falconry*, is a hawk's mewing, from the firſt change of her coat till ſhe turn white.

INTERMEZZO, *Ital.* Intermede, *Fr.*, a piece of muſic, a dance, or a ſhort dramatic ſcene, generally between two performers of different ſexes, exhibited between the acts of a ſerious opera, to vary the entertainment, and to relieve and enliven the audience, that may be too much oppreſſed and diſpirited by tragic ſcenes of great intereſt.

The ancient Romans had ſatires performed between the acts of their regular comedies; and theſe were afterwards exhibited as farces at the end of pious pieces.

Tragicomedies had a very early admiſſion on the ſtage at Bologna during the 17th century: as Andromeda, Tragicomedia, ſet by Girolamo Giacobbi, maeſtro di cappella of San Petronio, and founder of the Academy de' Filomaſi, in that city, was performed in 1610; and Amor vuol Gioventa, ſchirzo dramatico, at Viterbo, 1659. Muſica di Giambatiſta Mariani, 1659. But the only real burlettas which we have met with are Girello, Drama Burleſca, ſet by the famous Piſtocchi, 1672, which was repreſented at Venice by little figures of wax: I dos Diogeno, dramma burleſca per muſica, and Agripina in Baja, Schirzo drammatico per muſica, were both performed at Ferrara, 1687.

There are intermezzi, ſays Rouſſeau, that are true comic or burleſque dramas, which detach the audience from the intereſt of the principal piece, without taſte or reaſon. As the dance in Italy is never analogous to the drama, they are obliged to admit it on the ſtage as an intermezzo; "but this is not what I blame; on the contrary, I think it may be uſeful to efface, by an agreeable dance, the melancholy impreſſions left by the events of a grand ſerious opera; and I ſee plainly that the ſubject of this dance ſhould have no connection with the piece; but what offends me, continues the citizen of Geneva, is that they deſtroy all the intereſt that has been excited, and render each act a new piece." We ſuppoſe he means that the ballet ſhould be given at the end, not in the middle of the opera.

INTERMITTENT, a thing which ceaſes its action for ſome time; which time is called the *interval.*

Intermittent, in *Medicine*, any animal motion or action, which ceaſes and returns at intervals. The period of ceſſation is termed the *interval*, or *intermiſſion.*

Thus thoſe fevers which, after continuing ſeveral hours, altogether go off, and again return at certain intervals, as of one, two, or three days, are called *intermittent* fevers, in contradiſtinction from thoſe which go through their courſe with little variation, or with regular diminution and aggravation only; the former being called *continued*, the latter *remittent* fevers. See Fever and Ague.

Various other diſorders, beſides the acute fevers juſt mentioned, put on the *intermittent* form; ſuch as head-ache, eſpecially the *hemicrania*, or head-ache of one ſide of the head, the *megrim*, and ſometimes the *tic douleureux*; and pains, ſeated in various other parts of the body, as in the liver, bladder, uterus, &c. It is extraordinary, and does not eaſily admit of any explanation, that, in parts of the body, ſuffering ſevere organic diſeaſe, and actually much injured in their ſtructure, the pain connected with this diſorder ſometimes becomes regularly *intermittent* with intervals of abſolute freedom from the diſtreſs; while of courſe no variation can have occurred in the morbid ſtructure. Such intermiſſions we have witneſſed in cancerous and ulcerated conditions of the womb; and, in ſuppuration in the brain. But, indeed, it is equally difficult to account for the fact in all inſtances; and no ſpeculations have yet enabled us to explain, why the veſſels of any part, (as of the ſupra-orbital notch, in the caſe of *megrim*,) or of the whole ſyſtem, (as in *ague*,) ſhould take on an extraordinary action at regular but diſtant periods, and continue only their ordinary action in the intervals: whether the parts be actually diſeaſed in ſtructure or not, the periodical recurrence and ceſſation of increaſed vaſcular action is equally inexplicable. Dr. Darwin has ingeniouſly endeavoured to refer theſe periodical changes to the influence of our diurnal habits, in regard to activity and ſleep, exhauſtion of ſenſorial power and invigoration, and to the diurnal periods of heat and cold, light and darkneſs, &c. upon all the actions of our frame. That theſe circumſtances greatly influence the operations of the animal body, cannot be doubted: and were all the periods of action and intermiſſion *diurnal* only, we might admit the generalization as correct. But it is not eaſy to diſcover how the very frequent *intermiſſions* of diſeaſe, which continue for *tertian* periods, that is, during an interval of forty-eight hours, and ſtill more thoſe which continue for *quartan* periods, of ſeventy-two hours, can be referred to this general law. See Darwin, Zoonomia, vol. i. ſect. 36.

The bark of the cinchona, and ſome other bitter vegetable ſubſtances, it is well known, poſſeſs a conſiderable degree of power, when adminiſtered during the intermiſſions, for preventing the recurrence of diſeaſes of this claſs. But a remedy has been added to the liſt of the materia medica, which ſeems to have a ſpecific virtue of arreſting all *intermittent* affections: we mean the *arſenic*, which had long been uſed as an empiric noſtrum, under the appellation of the "taſteleſs ague-drop," but which was firſt prepared in a ſafe and manageable form by the late Dr. Fowler, of York, and is now introduced into the pharmacopeia of the College of Phyſicians of London. This medicine has not only been adminiſtered with decided benefit in intermittent fevers; but alſo in the intermittent head-ache and *megrim*, with the moſt marked ſucceſs. And we have found it, in more inſtances than one, ſpeedily arreſt the intermitting pains in diſeaſed uterus, and other organic painful diſeaſes. In a word, arſenic appears to have a ſpecific remedial power over periodical diſorders. But in caſes of organic diſeaſe, its influence is of courſe confined to the periodic pains connected with them, and is not exerted upon the fixed and continued affection.

The term *intermittent* is alſo applied to the *pulſe*, when, after an indefinite number of beats, it ſtops during the time of one pulſation, or loſes a ſtroke. This is ſometimes a formidable ſymptom, when connected with other ſigns of affection of the brain, or of the heart itſelf; but it is more commonly of minor import, being connected with indigeſtion, and a general irritability of the ſyſtem, and is removable by correcting the ſtate of the ſtomach and other organs concerned in the chylopoetic proceſs. See Pulse.

INTERMITTING Springs, in *Natural Hiſtory*, or ebbing and flowing wells, are phenomena which attracted a great deal of attention in former times, and ſeveral works on natural philoſophy contain explanations of the principles on which they might, by a proper application of the ſyphon, be made, by art, ſo as afterwards to be ſelf-acting: it can ſcarcely be doubted but ſome of the intermitting ſprings were natural, or produced their ebbing and flowing or intermiſſion, without the aſſiſtance of art, perhaps that on the N.N.W. ſide of Tideſwell town in Derbyſhire, which formerly exiſted and gave the name to the town, may have been of this number; and perhaps alſo Laywell ſprings at Brixham, in Devonſhire, may have been natural; but Mr. Farey, in his recent Report on Derbyſhire, (vol. i. p. 288.) ſtates the ebbing well at Barmoor, between Caſtleton and Chapel-en-le-Frith, on the ſkirt of Peak foreſt, in Derbyſhire, to occupy the ſcite of an old ſtone-quarry, in the firſt limeſtone rock, and to be evidently the work of art; he alſo mentions an artificial well of this kind lately made in the pariſh of Chapel-en-le-Frith. See Spring.

INTERNAL Angles, are all angles made by the ſides of any right-lined figure within.

In a triangle, as KLM (*Plate* VIII. *Geometry*, *fig.* 103.) the angles L and M are particularly called *internal* and *oppoſite*, in reſpect of the external angle IKM, which is equal to them both. See *Internal* Angles.

Internal *Angle*, is alſo applied to the two angles formed between two parallels, by a line interſecting thoſe parallels, on each ſide the interſecting line.

Such are the angles z and y, and x and s (*Plate* VIII. *Geometry*, *fig.* 104.) formed between the parallels OP and QR, on each ſide of the interſecting line ST.

The two internal angles are always equal to two right angles.

Internal and *Oppoſite Angles*, are alſo applied to the two angles z and x, formed by a line cutting two parallels.

Theſe are reſpectively equal to A and u, called the external and oppoſite angles.

Internal *Affection*, *Denomination*, *Ear*, *Modes*, *Orthography*, *Place*, *Senſe*. See the ſubſtantives.

Internal *Plans*, in *Mining*, ſignify, according to M. Werner (New Theory of Veins, Tranſl. p. 104.), the internal drawings, or ſections as they are called in this country, of the mines and the ſtrata, or of rocks in which they occur. Sections of particular diſtricts, formed into tablets inlaid with the principal rocks and minerals of ſuch diſtricts, have long been made by Mr. White Watſon of Bakewell, in Derbyſhire, Mr. Elias Hall of Caſtleton, Brown and Co. of Derby, and others, but it has juſtly been objected to all the tablets or ſections of this kind which we have ſeen, that they repreſent ſome imaginary hill or mountain, inſtead of being in any way proportioned to, or made to repreſent, the actual ſtrata and outline of any diſtrict. Now that mineral ſurveying, or the methods of obtaining a knowledge of the interior of ſtratified diſtricts, as well as of aſcertaining whether they are ſo ſtratified, has been fully explained in the Report to the Board of Agriculture on the County of Derby, by Mr. John Farey, ſenior, and illuſtrated by a ſurvey of that intereſting and difficult county, we hope that the making of accurate and natural repreſentations or tablets of the interior, or ſections of different diſtricts, will be attempted. A very neat and intereſting way of diſpoſing a tablet of a gentleman's mineral ſtrata in his eſtate, is in the front of his chimney-piece, inſtead of the flat or carved marble ſlab now generally uſed. Mr. William Milnes of the Butts in Aſhover, in Derbyſhire, has employed Mr. W. Watſon to make him ſuch a chimney-piece, which forms a very intereſting object as well as a ſubject of contemplation to his friends and viſitors.

INTERNODIUM, in *Anatomy*, the ſpace between two articulations. It is only applied to the fingers, where it is employed in naming ſome of the muſcles; at preſent it is uſed only in the extenſors of the thumb, which are called extenſor primi, and ſecundi internodii pollicis.

INTERNODIUM, in *Botany*, the ſpace that is between two knots, or joints, of the ſtalk of a plant; *e. gr.* of the ſtalk or ſtraw of wheat, or other corn.

INTERNUS MALLEI, in *Anatomy*, one of the muſcles of the oſſicula auditus, called more commonly tenſor tympani. See EAR.

INTEROSSEI, a number of ſmall muſcles of the hands and feet, ſo named from being ſituated in the intervals of the metacarpal and metatarſal bones.

The *interoſſei* of the hand are ſeven; *viz.* two for each of the three middle fingers, and one for the little finger. The abductors and the adductor of the thumb ſupply the places of the interoſſei in that member; and the adductor oſſis metacarpi indicis holds the place of an internal interoſſeous muſcle in the little finger. The interoſſei produce the lateral motions of the fingers to which they correſpond; they may therefore be moſt conveniently arranged as abductors and adductors of their reſpective fingers. More commonly, however, they are divided into two claſſes, according as they are placed towards the palm or the back of the hand, and diſtinguiſhed by the names of interoſſei interni priores or palmares, and externi poſteriores or dorſales. In this diſtribution, the internal claſs contains four muſcles, which are named by Albinus, 1, indicis prior, and 2, poſterior; 3, prior annularis; 4, prior auricularis; the external has only three; *viz.* 1 and 2, prior et poſterior digiti medii; 3, poſterior annularis. Sometimes they are diſtinguiſhed numerically, beginning from the thumb. The abductor indicis, or ſemi-interoſſeus, (ſee ABDUCTOR,) forms the firſt external interoſſeus of Soemmerring; who therefore enumerates four external interoſſei. This anatomiſt makes only three internal interoſſei; the 1ſt, internal interoſſeus of Albinus, being one of the heads of Soemmerring's firſt external interoſſeus. Both claſſes are called by ſome French writers metacarpo-ſus-phalangiens.

Interoſſei of the fore-finger. The abductor (prior indicis of Albinus, one of the heads of the firſt external interoſſeus of Soemmerring and others) is attached to the radial flat ſurface of the metacarpal bone of the fore-finger; it forms a tendon towards the finger, which is inſerted, in common with that of the abductor indicis, into the radial ſide of the metacarpal end of the firſt phalanx of that finger, having alſo a ſlight connection to the extenſor tendon; the radial artery dips into the palm of the hand between this muſcle and the abductor indicis.

The adductor of the fore-finger (poſterior indicis, Alb.) is placed towards the palm of the hand. It ariſes from the ulnar flat ſurface of the 2d metacarpal bone, and from the ligaments which unite that to the trapezoid bone. At the end of the metacarpus it forms a ſmall flat tendon, paſſes over the articulation of the index and metacarpus, the ſide and back part of the firſt phalanx, the articulation between the firſt and ſecond phalanges, and the dorſal ſurface of the 2d phalanx. On the middle of the latter bone, it meets at an acute angle with a correſponding tendon of the lumbricalis, and the two tendons unite into a broader one, which is ſlightly contracted and inſerted into the middle prominence of the back of the third phalanx. About the middle of the firſt phalanx, or rather ſooner, it becomes united to the broad tendon of the extenſor, from which it ſeparates a little before the termination of that tendon.

This connection is formed by a thin and broad tendinous expanſion, which cloſely covers the articulation of the index with the metacarpus.

Interoſſei of the middle finger. The abductor (prior digiti medii) is placed towards the back of the hand: it ariſes from the ulnar ſide of the ſecond, and radial ſide of the third metacarpal bone; and has a middle tendon, in which two oblique rows of fibres terminate. The courſe of its tendon correſponds exactly to that of the preceding, and is united, at its termination, to that of the ſucceeding muſcle.

The adductor of the middle finger (poſterior medii digiti) is placed alſo towards the back of the hand, and has a ſimilar form to the laſt muſcle. It ariſes from the third and fourth metacarpal bones, and is inſerted in the manner already deſcribed.

Interoſſei of the ring-finger. The abductor, (prior annularis,) placed towards the palm, is attached to the radial ſide of the fourth metacarpal bone, and to the ligaments which connect it to the carpus. It terminates in a tendon ending as already deſcribed. The adductor (poſterior annularis) is placed towards the back of the hand, ariſes from the ulnar ſide of the fourth, and from the radial ſide of the fifth metacarpal bone, and has a middle tendon placed between two planes of fibres, and inſerted like the preceding ones.

The *interoſſeus* of the little finger. This finger has only an abductor (prior auricularis), which ariſes from the radial ſurface of the fifth metacarpal bone, and from the ligaments joining it to the carpus. Its tendon has a courſe and inſertion like thoſe of the former.

The expanſions of the interoſſei, where their tendons begin to join thoſe of the extenſors, are connected by many fibres to the capſules of the joints formed between the metacarpal bones and the firſt phalanges: their aponeuroſes are alſo ſtrengthened by the tendons of the lumbricales. The relations of the interoſſei to the ſurrounding parts may be conſidered in a general view. On the ſides they correſpond to the metacarpal bones, and they are reciprocally in contact with each other. They are covered in front by the tendons of the flexor profundus, by the lumbricales, and, ſo far as the three firſt are concerned, by the adductor pollicis. They are retained, towards the end of the metacarpus, by the anterior tranſverſe palmar ligament, at the level of which they are all directed backwards. On the poſterior ſurface the firſt interoſſeus is ſubcutaneous: the others are covered by thin aponeuroſes attached to the correſponding metacarpal bones, ſeparating the interoſſei from the extenſor tendons, and in their intervals from the integuments. Their expanded tendons are placed between the phalanges and the ſkin.

Theſe muſcles ſeem to perform, as their primary uſe, the abduction and adduction of the fingers. They ſerve to fix the extenſor tendons; which, not being covered by any fibrous ſheaths, required this lateral ſupport. They partake this office with the lumbricales; when the two interoſſei of any finger act together, the extenſor tendon is drawn in the diagonal of their direction. If the fingers are extended, they will be fixed more firmly in this poſition; but if they are already bent, the flexion is increaſed by the action of the interoſſei, which exert themſelves ſo much the more effectually, as their tendon falls perpendicularly in the moving part. From the courſe which the tendons purſue, along the ſides to the backs of the fingers, they will have the effect of extending the middle and laſt joints. If the fingers are fixed, theſe muſcles may bend the metacarpus to them.

The *interoſſei* of the foot hold the ſame relation to the metatarſus, as thoſe of the hand do to the metacarpus; and are arranged into an internal and an external claſs, or a ſuperior and an inferior; of which the former is placed towards the back, and the latter towards the ſole of the foot. They are the adductors and abductors of the toes; and are ſeven in number, three internal, and four external. Of theſe, ſix belong to the three middle toes, and one to the little toe, their place being ſupplied, in the great toes, by its proper muſcles.

The *internal interoſſei* are the adductors of the third, fourth, and fifth toes. They agree very nearly in their mode of origin, figure, courſe, termination, and action. They are ſmall and tendinous at their commencement; grow gradually thicker and broader, then again decreaſe, and form long and flat tendons at the digital end of the metacarpus. They all paſs forwards from the metatarſus towards the toes, and end at the tibial ſides of the metacarpal extremities of their reſpective toes, near the terminations of the lumbricales. Their tendons are cloſely connected to the capſules of the firſt joints of the toes, to thoſe of the lumbricales, and of the extenſors. The firſt ariſes from the poſterior part of the under ſurface of the third metatarſal bone on its tibial ſide: the ſecond from the correſponding part of the fourth, and the third from that of the fifth metatarſal bone. The two latter are alſo connected to the ſheath which contains the tendon of the peroneus longus.

The *external interoſſei* are 1 and 2, the adductor and abductor of the ſecond toe, 3, the abductor of the third, and 4, the abductor of the fourth. The three latter reſemble each other, and reſemble alſo the external interoſſei of the hand, in having double origins: each of them has two heads, ariſing from the two contiguous metatarſal bones, tendinous at their commencement, uniting at acute angles in a middle tendon, which paſſes forwards to the toes. The tendons are thicker and broader than thoſe of the internal interoſſei, connected in the ſame way to the capſules of the firſt joints, and inſerted in the ſame manner, but on the oppoſite ſides of the firſt phalanges. The abductor of the ſecond toe has its larger origin from rather more than the poſterior half of the third metatarſal bone, on its outer or peroneal ſurface; the ſmaller head comes from the oppoſed ſurface of the ſecond bone. The abductor of the third toe has a larger origin from the fourth, and a ſmaller from the third bone; and the abductor of the fourth has the ſame relation in its origin to the fifth and fourth metatarſal bones. The adductor of the ſecond toe differs from the other external or ſuperior interoſſei, in ariſing from one bone only: its origin is derived from more than the poſterior half of the inner or tibial ſurface of the ſecond metatarſal bone: its inſertion is ſimilar to that of the others.

The interoſſei of the foot have the following relations to the ſurrounding parts: On the back of the foot they are covered by the tendons of the two extenſors, and by a very thin aponeuroſis, which is ſometimes ſcarcely ſenſible, and which is extended in the intervals of the metatarſal bones. In the ſole they are in contact with the muſcles of the great and of the little toe, with the tendons of the flexor longus digitorum and the lumbricales, and with the deepſeated plantar veſſels. On their ſides they correſpond to each other, or to the metatarſal bones.

The motions produced by theſe muſcles are analogous to thoſe of the correſponding ones in the hand. In the firſt place they are adductors and abductors of their reſpective toes. They may act as flexors of the firſt phalanges through the means of their tendons affixed to theſe bones, more particularly when the firſt joints are already ſlightly bent; for they are then directed obliquely or perpendicularly to the moveable point, with which, in the extended ſtate, they are parallel. By the portions, which they detach to the extenſor tendons, they may aſſiſt the extenſion of the laſt phalanges; but it is neceſſary that the extenſors ſhould have previouſly acted in ſome degree, to carry the laſt phalanx upwards and backwards, and this motion is then increaſed by the interoſſei. They ſerve alſo, as in the hand, to fix the extenſor tendons laterally.

INTEROSSEUS, an epithet of certain organs of the body, particularly in the fore-arm and leg, which are ſituated between two bones. The interoſſeous artery of the fore-arm is a branch of the ulnar, and is divided into an anterior and a poſterior interoſſeous branch. In the leg, the peroneal artery is ſometimes deſignated by this term. The interoſſeous ligaments are aponeurotic expanſions attached to the oppoſed edges of the bones of the arm and leg, and filling up the intervals between theſe bones. See ARTERY and EXTREMITIES.

INTERPLEADER, *Bill of*, in *Law*, is where a perſon who owes a debt or rent to one of the parties in a chancery ſuit, but, till the determination of it, he knows not to which, deſires that they may interplead, that he may be ſafe in the payment. In this laſt caſe it is uſual to order the money to be paid into court, for the benefit of ſuch of the parties to whom, upon hearing, the court ſhall decree it to be due. But this depends upon circumſtances; and the plaintiff muſt alſo annex an affidavit to his bill, ſwearing that he does not collude with either of the parties.

INTERPOLATION, a term uſed by critics in ſpeaking of ancient writings and manuſcripts, in which ſome ſpurious additions or alterations have been ſince made.

To eſtabliſh or aſcertain an interpolation, P. Ruinart gives us the five following rules. 1. That the piece ſuppoſed to be interpolated appear to have all the antiquity it pretends to. 2. That there be good proofs that it has been interpolated. 3. That the ſuppoſed interpolations agree to the time of the interpolator. 4. That the interpolations do not touch the foundation of the work; and that they be not too frequent, nor entirely disfigure the piece. 5. That the reſtitution made, agree perfectly to the reſt of the work.

Interpolations have occaſioned ſeveral of the various readings in the New Teſtament. Michaelis, in his "Introduction to the New Teſtament," and alſo other writers, have ſuggeſted how theſe were introduced, and how they may be diſtinguiſhed from the original text. *E. G.* If for a paſſage that is not abſolutely neceſſary to the conſtruction, various readings are found that differ materially from each other, we have reaſon to ſuſpect its authenticity; and that all the readings are interpolations of tranſcribers, who have attempted by different methods to ſupply the ſeeming deficiency of the original. An interpolation is ſometimes betrayed by the circumſtance of its being delivered in the language of a later church. To this purpoſe Michaelis obſerves, that in the time of the apoſtles the word "Chriſt" was never uſed as the proper name of a perſon, but as an epithet expreſſive of the miniſtry of Jeſus, and was frequently applied as ſynonymous to "Son of God." The expreſſion, therefore, "Chriſt is the Son of God," (Acts, viii. 37.) is a kind of tautology, and is almoſt as abſurd as to ſay Chriſt is the Meſſiah, that is, the Anointed is the Anointed. But the word being uſed in later ages as a proper name, this impropriety was not perceived by the perſon who obtruded the paſſage on the text. If one or more words, that may be conſidered as an addition to a paſſage, are found only in MSS., but in none of the moſt ancient verſions, nor in the quotations of the early fathers, we have reaſon to ſuſpect an interpolation. Acts, viii. 39. πνευμα [αγιον επεπεσεν επι τον ευνȣχον, αγγελος δε] Κυριȣ ηρπασε τον φιλιππον, is an inſtance of this kind, where the words between the crotchets are probably ſpurious. Interpolations of conſiderable length are occaſioned ſometimes in the following manner: The owner of a MS. makes a note in the margin, either explanatory of ſome narrative in the text, or containing an account of ſome event that was handed down by tradition; which MS., being afterwards tranſcribed, the copyiſt writes text and notes without diſtinction in the body of his work. "I am perſuaded," ſays Michaelis, "that John, v. 4., a very ſuſpicious paſſage, and omitted in a very great number of MSS. has been intruded in this manner into our preſent text, and that this ſcholion was written originally not in Greek, but in ſome oriental language." The diſputed paſſage in 1 John, v. 7. may probably be a ſpecimen of this kind of interpolation. Its ſpuriouſneſs has been ſhewn by ſir Iſaac Newton, in a letter to Le Clerc, firſt publiſhed in London in 1754, and more correctly by Dr. Horſley in 1785, from the author's origin al copy. (See his edition of Newton's Works, vol. v. p. 495—531.) This letter, ſays Dr. Marſh, is leſs known than it deſerves, as the immortal author has diſplayed in it as much critical knowledge, as penetration in his mathematical inquiries. The queſtion has been likewiſe examined, and with great impartiality, by Bengel, in his "Apparatus Criticus," p. 458—482. 2d ed.; and the diſpute has been ſatisfactorily terminated by the eminently learned Porſon, in his "Letters to Travis," publiſhed in 1791. See *Various* Readings.

Interpolation, in *Algebra*, is uſed for the finding an intermediate term of a ſeries, its place in the ſeries being given; and the method of doing this is called the *method of interpolations*.

When the algebraic equation of the ſeries is given, the term required, whether it be a primary or intermediate term, may be found by the reſolution of affected equations; but when this equation is not given, as it often happens, the value of the term ſought muſt be exhibited by a converging ſeries, or by the quadrature of curves.

When the firſt, ſecond, and other ſucceſſive differences of the terms of a ſeries become at laſt equal, the interpolation of any term of ſuch a ſeries may be found by ſir Iſaac Newton's differential method.

The method of interpolation was firſt invented by Mr. Briggs, Savilian profeſſor of Geometry at Oxford, and applied by him to the calculation of logarithms. His principles were followed by Dr. Wallis, who made ſeveral ingenious applications of this theory; and by Reginald and Mouton, in France. Sir Iſaac Newton, in lemma 5. lib. iii. Phil. Princip. Mathem. gave a moſt elegant ſolution of the problem for drawing a curve line through the extremities of any number of given ordinates; and in the ſubſequent propoſition applied the ſolution of this problem to that of finding from certain obſerved places of a comet, the place of it at any given intermediate time. Dr. Waring, who adds, that a ſolution ſtill more elegant, on ſome accounts, has been ſince diſcovered by Meſſrs. Nicholi and Stirling, has alſo reſolved the ſame problem, and rendered it more general, without having recourſe to finding the ſucceſſive differences.

The theory of interpolation is of very extenſive uſe, not only in pure analyſes and geometry, but in various other ſubjects of mathematical inquiry and computation, and particularly in aſtronomy; we ſhall therefore endeavour to explain the principles upon which it is founded, and ſhew its application in a few caſes to practical operations.

Firſt, then, let a, b, c, d, e, f, &c. repreſent any ſeries of ſimilar quantities, and let the difference between the firſt and ſecond, the ſecond and third, the third and fourth, &c. terms, be taken; and theſe ſeveral remainders will form what is called the firſt order of difference; then again, let the differences of theſe differences be taken in the ſame way; and the differences of theſe laſt again the ſame, and ſo on, which will give the following reſult, obſerving, that for the convenience of exhibiting the operation, we have only retained the firſt remainders in each ſucceſſive ſubtraction.

ſeries	$a \quad b \quad c \quad d \quad e \quad f$, &c.
1ſt diff.	$a - b$
2d diff.	$a - 2b + c$
3d diff.	$a - 3b + 3c - d$
4th diff.	$a - 4b + 6c - 4d + e$
5th diff.	$a - 5b + 10c - 10d + 5e - f$
6th diff.	$a - 6b + 15c - 20d + 15e - 6f + g$
	&c. &c. &c.

Now the co-efficients of theſe terms are reſpectively the ſame as thoſe of the co-efficients of the binomial, and the order of their generation evidently follows the ſame law, and therefore we may conclude with equal certainty, that the nth difference of any ſeries of quantities will be expreſſed by the formula

$$a - nb + \frac{n(n-1)}{1.2}c - \frac{n(n-1)(n-2)}{1.2.3}d$$
$$+ \frac{n(n-1)(n-2)(n-3)}{1.2.3.4}e - \text{\&c.}$$

Now it is obvious, that if the given quantities be ſuch, that any order of their differences become equal to 0, that any one of thoſe quantities may be accurately expreſſed in functions of the others; thus, for example, ſuppoſe the fourth difference to become zero, that is

$$a - 4b + 6c - 4d + e = 0$$

then will $$c = \frac{-a + 4b + 4d - e}{6}$$

and it is obvious that any other of theſe quantities might be expreſſed in a ſimilar manner; and therefore, if all thoſe quantities but one be known, that one may be aſcertained. Thus, by way of illuſtration, ſuppoſe we had the three ſquares $10^2 = 100$, $8^2 = 64$, and $7^2 = 4$, and the ſquare of 9 was required; ſince the third differences of ſquares equal 0, we ſhould have $9^2 = \frac{100 + 3 \cdot 64 - 49}{3} = 81$, and the ſame is obviouſly true of any terms of which the differences vaniſh.

But if the differences do not vaniſh, then any intermediate term found by this method only approximate towards the true reſult, which is however ſufficiently correct in a number of caſes; thus, in finding any logarithm, of which thoſe conſecutive to it are given, the above formulæ may be ſucceſsfully employed; for though, in fact, the differences of logarithm never become zero, yet their fourth differences are ſo ſmall, that by conſidering them as 0, the error will not effect the truth of the reſult to 8 or 9 places of decimals.

Exam.—Given the logarithms of 101, 102, 104, 105, to find the logarithm of 103.

Here, calling the log. of $101 = a$, of $102 = h$, $103 = c$, $104 = d$, and $105 = e$; and conſidering the fourth differences of theſe $\text{logs} = 0$; we ſhall have from the formula

$$a - 4b + 6c - 4d + e = 0$$

$$c = \frac{4(b + d) - (a + e)}{6}$$

Hence the following computation:

$$\begin{array}{lrl}
\text{log. } 101 = & 2.0043214 & = a \\
\text{log. } 102 = & 2.0086002 & = b \\
\text{log. } 104 = & 2.0170333 & = a \\
\text{log. } 105 = & 2.0211893 & = e \\
\hline
 & 4.0256335 & = b + d \\
 & 4 & \\
\hline
 & 16.1025340 & = 4(b + d) \\
\text{ſubtr.} & 4.0255107 & = a + e \\
\hline
 & 6)12.0770233 & \\
\hline
\text{log. } 103 = & 2.0128372 & \text{as required.} \\
\hline
\end{array}$$

This method of finding the intermediate logarithms between others that are known, though of little importance in the preſent ſtate of the ſciences, was of very eſſential ſervice to the original computers; and to whom the invention of it is due, or more properly to Briggs alone, who ſeems to have been the firſt that entered upon the inveſtigation of this theory.

This doctrine is applied with great ſucceſs in various aſtronomical operations, and is the means of ſaving in many caſes immenſe laborious calculations. Thus, for example, in finding the places of ſome of the planets, whoſe motion is not very rapid, it will be ſufficiently accurate to find their places by calculation for every fourth or fifth day, and then by means of the method above deſcribed, their places for all the intermediate days may be found by interpolating between the known terms, which method will give a reſult much nearer the truth, than by proportional parts, becauſe this ſuppoſes a uniformity both in motion and time, which is not correct.

Again, in computing the moon's place for any particular hour, ſuppoſing its place for every day at noon to be given, the method of interpolations may be applied with great ſucceſs, the reſults having ſcarcely any ſenſible difference from thoſe that ariſe from actual computation, and we may thus frequently avoid one of the moſt laborious of aſtronomical calculations.

By this means alſo, the place of a comet at any particular time may be aſcertained, from obſervations made on it prior to, and ſubſequent to, that preciſe period, as alſo the times of the equinoxes and ſolſtices, which are determined much more accurately by this method than can be done by proportional parts, for in this, we are obliged to ſuppoſe that the ſun's declinations increaſe and decreaſe proportionally to the diſtance of this body from the equinoctial point; which is evidently a falſe hypotheſis. In fact, aſtronomy has derived more aſſiſtance from this theory than any other of the mathematical ſciences, although it has been applied to other purpoſes with very great ſucceſs; but in order to render its application thus general, a much more accurate and extended inveſtigation of the theory than that which has been at preſent mentioned becomes neceſſary, and of which we propoſe to give a ſlight view in the ſubſequent part of this article.

The general problem to be reſolved in all theſe caſes is this. Having given two ſeries of numbers, which correſpond with one another, according to a certain law, and of which one may be called the ſeries of roots, and the other the ſeries of functions, to find an intermediate number, between two functions, which ſhall anſwer or correſpond to a given intermediate number between two roots. This problem is treated of in all its generality by Newton, in his "Methodus Differentialis," and by Stirling in his "Tractatus de Summatione, &c.;" ſee alſo Lacailles Aſtronomy, and a paper by Mayer in the Acta. Petrop. tom. ii. page 108; alſo an excellent memoir by Lalande, tranſmitted to the Academy of Sciences of Paris for 1761; in which he has ſhewn that in calculating the moon's place, and much more that of any other of the heavenly bodies, whoſe motions are more regular; it will always be ſufficient to conſider only the third differences, and in many caſes only the ſecond differences will be requiſite, and ſometimes only the firſt; in fact he has ſhewn how, and to what degree of accuracy, the method of interpolation may be employed in moſt caſes. The ſame author has alſo a very complete article on this ſubject in the Encyclopédie Méthodique, where, in explaining the nature of aſtronomical interpolation, he ſays, ſuppoſe a ſeries of numbers 0, 1, 3, 6, 10, 15, 21, &c. of which the differences are unequal, but follow a certain law, being in fact in arithmetical progreſſion as 1, 2, 3, 4, 5, 6, &c. ſo that the ſecond differences are conſtant, and equal to unity. Now if we take the alternate terms of this ſeries, as for inſtance 0, 3, 10, 21, &c. the firſt differences will be 3, 7, 11, &c. and the differences of theſe differences will be conſtant, and equal to 4; that is four times greater than before; becauſe in doubling the interval, we have for the firſt difference the ſum of 1 and 2, and in the other the ſum of 3 and 4; hence it follows that the ſecond difference increaſe in the ratio of the differences between 2 and 3, and 1 and 4: the increaſe, therefore, being equal to three times the firſt, this ſecond difference will be equal to four times that; and if we took every third number, the ſecond difference would be 9, and ſo on.

Thus, in general, the ſecond differences increaſe as the ſquare of the intervals of the numbers; and hence we have the following rule for ſupplying the intermediate terms of a ſeries of numbers of which the law of their generation is uniform.

For example, let there be four numbers which may repreſent longitudes, obſerved at the interval of 12 hours each; and of which the three differences are 78, 222, and 366, ſo that their ſecond differences will be conſtant, and equal to 144; according to the following tablet.

Hours	Nos.	1ſt Diff.	2d Diff.
0	0		
12	78	78	144
24	300	222	144
36	666	366	

Such an example is the moſt ſimple that can be conceived in interpolation, but ſimple as it is, it is all that is required in aſtronomy, even for the motion of the moon, which is the moſt irregular of all the planetary bodies; ſuch at leaſt is the aſſertion of Lalande in the article of the Encyclopédie above quoted.

Now knowing the above numbers, or obſerved longitudes, for every 12 hours, it will be eaſy, by means of the above rule, to find the ſame for every ſix hours; for ſince, in this caſe, the ſecond differences ought to be only one-fourth of thoſe above, that is 36, it will therefore only be neceſſary to conſtruct a ſeries of numbers beginning at 0, whoſe ſecond differences are 36, and whoſe ſecond term ſhall be 78; therefore $\frac{78 - 36}{2} = 21$ is the firſt term of the firſt differences; and all the other terms will be found by adding ſucceſſively to this, the conſtant ſecond difference 36; thus

1ſt diff.		21,	57,	93,	129,	165, 201
Nos. or long.	0.	21,	78,	171,	300,	465, 666.

But if, inſtead of interpolating one term between each of the given numbers, it had been required to interpolate two terms, then we muſt have taken a ninth part of the above ſecond difference, *viz.* 16, and found from hence a ſeries of numbers whoſe ſecond difference ſhould be 16, and the third term of the ſeries = 78. Now in order to find this ſeries, it will be ſufficient to find the firſt term of the 1ſt differences, as all the reſt that is required may be determined from this; ſuppoſe, then, this term to be x, which is alſo the firſt term of the required ſeries, then the ſecond will be $2x + 16$, and the third $3x + 48$; whence $3x + 48 = 78$, or $x = 10$; which gives for

the 1ſt diff.		10,	26,	42,	58,	74,	90,	106, &c.
Nos. or long.	0.	10,	36,	78,	136,	210,	300,	406, &c.

and on ſimilar principles may the interpolation in any other caſe be effected with the ſame degree of eaſe and accuracy; that is, generally, in order to interpolate any number of terms n, between any two given terms of a known ſeries, we muſt divide the ſecond difference of the given ſeries by $(n + 1)^2$, in order to have the ſecond difference of the new ſeries; and then again in order to obtain the 1ſt differences, we have this formulæ; where $d' =$ 1ſt term 1ſt diff. of the given ſeries; and $d'' =$ 2d difference new ſeries,

$$\text{1ſt term 1ſt diff.} = \frac{d'}{n+1} \pm \frac{n\,d''}{2};$$

which may be more conveniently expreſſed in terms of the 1ſt and 2d differences of the given ſeries as follows; $d' =$ 1ſt difference, $d' =$ 2d difference of the given ſeries, then the 1ſt term 1ſt diff. of the new ſeries, becomes

$$= \frac{2\,d'\,(n + 1) \pm n\,d''}{2\,(n + 1)^2},$$

and this term being thus determined, all the others are readily obtained; and conſequently alſo all the intermediate terms which were to be interpolated. The conſideration of ſecond differences, which render the interpolation ſo extremely eaſy, is, as we before obſerved, ſufficiently exact for the greater part of aſtronomical calculations, particularly in the conſtruction of tables; it was thus that Sharp in 1695 calculated his table of right aſcenſion and declination for every degree of latitude and longitude; having firſt calculated *trigonometrically* the ſame for every fifth degree, the other intermediate degrees having been aſcertained by means of the theory of interpolation. Mouton alſo, on ſimilar principles, calculated the declination of the ſun for every minute of longitude in ſeconds and thirds, having firſt found *trigonometrically* the ſame for every degree. In general, whatever be the nature of the calculation, it will be ſufficient to aſcertain rigorouſly by trigonometry, or otherwiſe, terms at ſuch a diſtance that their third differences may become zero, or ſo ſmall that no ſenſible error will ariſe in conſidering them as ſuch, and then all the intermediate terms may be ſupplied by the theory which has been inveſtigated. Lalande has publiſhed in the "Connoiſſance des Tems for 1771," a very commodious table for abridging theſe kind of operations, and there is another ſtill more extended in the "Recueil des Tables de Berlin."

The ſame theory of ſecond differences may alſo be conveniently applied to correct calculations and obſervations, that is, by aſcertaining the uniformity of the remainders or differences.

For example, a ſeries of obſervations being ſubmitted to this teſt, ought to have a certain order of their differences uniform, and if in any place ſuch a uniformity is not obſerved, one difference being greater, or leſs, than another, it may be concluded with certainty, that ſome error has been committed in the correſponding obſervation; the correction of which may be readily made, without repeating the obſervation; Lalande has alſo given, in his memoirs above-mentioned, general formulæ of correction, for all ſuch caſes, and which may be applied with the greateſt facility, and the correction computed to the utmoſt poſſible accuracy.

On nearly the ſame principles as the foregoing, the extraction of roots, as the ſquare root, cube root, &c. may be effected with great eaſe, by knowing certain equidiſtant roots. The application in this caſe being extremely ſimple, it may not be amiſs to enter a little into the explanation of it.

Let then

$$(x^3 + 1)^{\frac{1}{3}} = x + \frac{1}{3x^2} - \frac{1}{9x^5} + \frac{5}{81x^8} - \frac{10}{243x^{11}} + \text{\&c.}$$

$$(x^3 \quad)^{\frac{1}{3}} = x$$

$$(x^3 - 1)^{\frac{1}{3}} = x - \frac{1}{3x^2} - \frac{1}{9x^5} - \frac{5}{81x^8} - \frac{10}{243x^{11}} - \text{\&c.}$$

repreſent the cube roots of any three conſecutive numbers, the differences of which are

$$\text{1ſt diff.} \begin{cases} \frac{1}{3x^2} + \frac{1}{9x^5} + \frac{5}{81x^8} + \frac{10}{243x^{11}} + \text{\&c.} \\ \frac{1}{3x^2} - \frac{1}{9x^5} + \frac{5}{81x^8} - \frac{10}{243x^{11}} + \text{\&c.} \end{cases}$$

$$\text{2d diff.} \qquad \frac{2}{9x^5} + \frac{20}{243x^{11}} + \text{\&c.}$$

In the ſame way, was it neceſſary, we might have found the third and fourth differences, and ſo on; but in the caſe we ſhall ſuppoſe, of $x^2 > 1000$, or $x > 10$, this ſecond difference is ſufficiently exact, and even the ſecond term of this ſecond difference is ſo ſmall, that it may be omitted without affecting even the eleventh place of decimals, for taking $x = 10$, we have $\frac{20}{243\,x^{11}} = \frac{2}{2430000000000}$, which, when converted into a decimal, will not give an effective figure before the 11th place; we may, therefore, without any ſenſible error, call $\frac{2}{9x^5}$ the ſecond difference, which will remain conſtant for ſeveral terms, while our extraction is not carried farther than to eight decimal places. Suppoſing, therefore, the cube root of any two conſecutive numbers greater than 1000 to be known, that is, $\sqrt[3]{x^3-1}$, and $\sqrt[3]{x^3}=x$; the firſt difference is aſcertained by ſimple ſubtraction, and the ſecond difference is found by the formula $\frac{2}{9x^5}$; and with theſe data, we may calculate eight or ten of the ſubſequent roots, when a new computation becomes neceſſary.
